"Ramases" is not happy in his reference to Deuteronomy xviii. 2, which says, "Or a charmer, or a consulter with familiar spirits, or a wizard, or a necromancer." I respectfully deny that the passage proves that the Israelites believed in the immortality of the soul. It proves that the later Jews (near the time of the Captivity) were superstitious, and believed in demons and supernatural beings; but, as no one doubts but that they did, that proves nothing in dispute. When the great doctrine of the immortality of the soul is markedly absent from the Law of Moses, it is absurd to attempt to prove it by such a passage as the above; indeed, in no other case but in that of the Israelites would such an attempt be made; but in their case it is well known that words are twisted any way to suit certain popular theories, and are used naturally or non-naturally as is convenient. **Memnon.**

[26370.]—REFERRING to the letter of "Ramases" (26346, p. 133), I must say that this gentleman's assertions are very unconvincing.

1. If the Hebrews did not give all the links, then their genealogies are worthless, for the object of genealogy is to show that an unbroken chain extends from the first to the last person mentioned. The Hebrews themselves evidently meant to imply that they were complete.

2. Both the authorised and the revised versions say, "*in* the four hundred and eightieth year," not "*about*," therefore the original Hebrew must support the former reading. The revisers have not even thought it necessary to notice the various readings, if there be one.

3. "Ramases" does not explain where Matthew got his names from. We can understand the omissions on the "broken link" theory; but the additions are inexplicable. Why did Matthew insert names which are not to be found in the Old Testament lists?

4. As the Septuagint version was made about B.C. 280, while our present Hebrew text was only settled by the Masorethes about the 10th century A.D., the former may represent an older version than we have, and therefore its variations are of great consequence. But these variations do not help our chronology—they only raise difficulties.

5. Exodus distinctly says that "the king of Egypt spake to the *Hebrew* midwives." Mr. "Ramases" has evidently not read the Bible, for he

asserts they were "Egyptians." Only two midwives are spoken of, and if the Israelites increased so rapidly they must have had plenty to do.

6. Diodorus's sources of information were no doubt the same as those mentioned by Josephus in his work against Apion. Josephus cites some statements of Manetho, and others, in order to refute them; and says that Manetho, although his work was compiled from Egyptian records, relates some fables about the expulsion of the Jews from Egypt, "not from the Egyptian records; but," as he confesses himself, "from some stories of an uncertain original." (Book I. Part 16, Whiston's Translation.)

7. I fail to see that "Memnon" has contradicted himself. The great Hebrew scholars, Reuss, Kuenen, and others, have come to the conclusion that the language of the Pentateuch is much more like that of the Prophets in most parts than anything else. No one doubts the Mosaic authorship of these five books, for they are a perfect "mosaic" of different pieces, written by different authors at different times. The verse mentioned does not prove the belief of the Israelites in the Immortality of the Soul, for it only speaks of a "consulter with familiar spirits." Mr. "Ramases" twists this into having dealings with the spirits of the dead. He should purchase a Bible, and read it. There is no proof that the Israelites had any other idea of a future life than that which was common to all other Semitic nations—viz., that the soul went to an underground place, called "Sheol" in Hebrew, and "Sualu" in Assyrian, and slept there for ever. They had no such ideas as are contained in the Egyptian "Book of the Dead," until after their contact with the Persians. "Ramases" concludes by informing us that all "reliable evidence" from Eastern monuments supports the truthfulness of the Bible narrative. Evidence that does not is, therefore, unreliable according to him; so that the inscriptions of Sargon, who says that he carried away 27,280 of the Israelites, and replaced them by other peoples, and that two years afterwards the subjugated Israelites rebelled against him, and were defeated with their allies at Karkar, are not "reliable," because the Second Book of Kings says that all Israel was carried away, and none left but the tribe of Judah (II. Kings xvii. 18).

Mr. "Ramases'" objections to "Memnon" are simply cavillings and hairsplittings. He says nothing about the main question, as to the reliability of the Hebrew figures and dates. No one who has given any attention to the subject can have any doubts of the utter impossibility of getting any reliable data from them. Mr. Gerard Smith takes a few which he makes agree pretty well with Bunsen's chronology. But there are half a dozen other chronologists besides Bunsen, all different. Mariette Bey seems most followed just now. However, the departure of the Israelites cannot be placed before the time of Rameses II., for that king overran the whole of Palestine, crossed the Lebanon, and defeated the Hittites at Kadesh on the Orontes. He should have come into contact with the Jews if they had been in Palestine at that time. His son, Meneptah, has left us a monument of one of his campaigns, and he may have been the Pharaoh of the Exodus; but this is merely conjecture, although Manetho mentions a king Amenophis at this juncture, and he is consequently identified as the man "who knew not Joseph." We must wait for more light before deciding positively on one side or the other.

Menes.

SPECULA FIGURING.

[26371.]—My esteemed friend "Orderic Vital" invites remarks upon the method described a week or two ago in these pages; but the fact is the details, which would be highly interesting, are conspicuous by their absence. The probability is that the author's paper has been too much curtailed to make its meaning clear; but the idea of parabolising the surface in 10 minutes is too, too—well, too good to be true.

People talk readily enough about forming a truly spherical curve, as if the task were as easy as drawing on an old glove, while those who work at it know it is extremely difficult.

The statement that a *truly* spherical curve was obtained by rubbing together an 18in. concave and an 18in. convex must be looked upon as a hyperbolic expression, unless we limit the meaning of the word "truly" to a mechanical sense; but this is not sufficiently accurate for astro. reflectors. The method of correction mentioned, if carried out strictly and designedly, may be a somewhat new departure; but the same thing is done every day, more or less, unintentionally. When a speculum is not far removed from the parabola, and is tested *à la* Foucault with an artificial star at centre of curvature, it is easy to get at one point along the reflected cone of rays just the appearance as suggested by this mode of correction—namely, the deepened centre and an expanded marginal zone; but this does not prove the figure to be a parabola; in fact, it may be considerably over-corrected, or much under-corrected in those cases where the total aberration required reaches a considerable amount.

Increase of aperture, and not the focus, is the chief factor in increasing the aberration, operating, in fact, in a geometrical ratio, while the focus influences it in a proportional one, so that the paragraph which states "the rate of decrease required in the amount of correction is very rapid with the increase of radius of curvature" is somewhat inaccurate. Although "by decreasing the focal length the rays cross at a less acute angle," which is quite true, I think few will agree "that small variations in the reflecting surface have not so detrimental an effect," but will believe just the opposite of what is sought to be conveyed here.

I will leave Mr. Wassell to express an opinion as to the result likely to be obtained with a polisher graduated as shown in the woodcut on page 59. Personally, I should not care to try it, although the idea is ingenious; but I think I can see my way to avoid rings without running so much risk.

I can only express my regret once more that the article was not printed verbatim in this journal.

Ramsgate. J. C. Linscott.

A SIMPLE WAY OF MAKING GLASS MIRRORS.

[26372.]—It may interest the amateur optical readers of the English Mechanic if I describe to them a cheap and simple way by which I have finished a 10½in. glass mirror which defines very well, easily dividing Omega Leonis, Zeta Cancri, and Mu² Boötis. I may mention that this is not my first attempt at specula-making, having ground several by various processes for some years. Whoever tries this way of grinding and figuring must make Mr. Wassell's testing apparatus, so as to be able to see what he is doing when figuring. The glass discs I obtained from Mr. W. S. Scott, a contributor to the "E. M." Its cost was 10s. 6d. It was cast concave on one face with a radius of 14ft., the edge was nice and smooth, and required nothing doing to, so I proceeded to grind by placing it on five or six thicknesses of house-flannel, which was laid on a disc of wood 14in. in diameter, which I placed on a 56 gallon cask. This cask was placed in the centre of a room so as to be able to walk round it. The grinding tool was a 6in. disc of glass 1in. thick, which had been used for grinding a 6in. mirror, so that it had a convex curve on one face. The stroke used was to start from one side of the mirror, and in four or five zigzag strokes to reach the other, then take a step round the cask and repeat the stroke so as to reach the side of mirror first started from. This was continued through the various grades of emery until a surface was obtained fit for the polisher.

The polisher was made by covering the tool with pitch divided into 1in. squares with a straightedge, the stroke used the same as in grinding towards the end of the polishing. The tool must start about 1in. within the edge of mirror. Of course, it will go over the edge of mirror at the end of each stroke, but if it goes over the side as well the edge in testing will be found turned back. If these directions are followed, the mirror will have a regular curve with no sign of rings, but most likely hyperbolic in a slight degree. This can be corrected by using different sized polishers on the zone between the centre and edge. My polishers were 3in., 1½in., and some smaller made by sticking a cork on a penny, a halfpenny, and a farthing, and putting pitch on the other grooved after the manner described by Mr. Brashear in his paper on making flats. If an uneven surface is obtained with the smaller polishers, the large one will correct it if used as at first. Ninip.

HAS ENGLAND GONE UP-HILL OR DOWN-HILL DURING THE LAST FIFTY YEARS?

[26373.]—A "Socialist's" (26337, Oct. 8, p. 131) remark that the poorer class pawn their Sunday clothes on Monday, and redeem them on the following Saturday, is, unfortunately for themselves, only too common a practice; but in many cases this is caused rather from bad management than extreme poverty.

Referring to the hours of labour of the tramcar employés, the Birmingham and Central and the Aston Tramways Companies have lately reduced the hours of working to 12 per diem. The men receive a fair remuneration—the conductors a small bonus on the amount of business done in addition to regular wages.

I gather from the last paragraph of "A Socialist's" letter that it is unfair to accept dividends, and, of course, this gentleman would only invest in concerns which would be unable to declare them. U., Birmingham.

[26374.] — "A Socialist," in replying to "B. R.," talks as Socialists and Communists usually do—wildly.

One example will show how worthless are his facts. He states that "B. R.," on the question of population has ignored Ireland, and that in the last few years the population of that portion of our empire has decreased *millions* (the italics are his). In point of fact, I find "B. R.'s" figures include Ireland, and instead of millions in a few years, the decrease in 10 years (from 1871-81) was from 5,402,759 to 5,159,339, or about 240,000. So much for socialistic facts. The paragraph respecting savings banks is so vague I can neither make head nor tail of it.

"A Socialist" talks of the "real worker," as if the man who puts on an apron or stands at a bench is the only being who does any work, while, in point of fact, it will probably be found that the merchant, manufacturer, or capitalist is by far the hardest worker.

"Socialist" takes two cases, each of them representing only a small portion of the community, and each of them generally acknowledged as scandals to the 19th century, and treats them as if they were a fair sample of the position of the working classes of to-day. The idea of thus treating the downtrodden slopworkers and tramway men is so absurd that it needs no reply. I contend that the bulk of the working classes to-day earn at least 25 per cent. more than they did 20 years ago, and that for the generality of requirements a sovereign has increased its purchasing capacity at least another 25 per cent. in the same period.

Our correspondent next falls foul of the tramway shareholders, because he (the shareholder) did not lay the tram lines, and does not drive or conduct the car, forgetting or ignoring the fact that if the said shareholder had not worked hard at some other trade, the navvy, driver, and conductor would have little or no work to do, for want of capital.

The long and short of the matter is that Socialist and Co. want to reverse things, so that they can occupy the places of employers and capitalists, and they are prepared to go any length to achieve the object, even to driving the capital out of the country. I have sufficient confidence in the majority of the working classes to believe that while there may be troublous times ahead, in which we shall have to pass through a furnace which will destroy the dross of the paid agitators, socialists, and the like, yet the result will be that master and man will come to a better understanding of each others' rights and wrongs, and each will strive in the common cause of improving the welfare of our nation and the well-being of the population at large. H. G. E.

[26375.]—"Socialist" seems to be very excited, and charges me with furnishing incorrect statistics with regard to the population of England, Ireland, Scotland, and Wales. As I copied the numbers from "Whitaker's Almanack," I must make the compiler of that work responsible. My object for giving the population was not to show the great increase, but rather to show that the advances made in commercial transactions have been in a much greater ratio.

"Socialist" next takes exception to my *implying* that "the poor are less poor" because the deposits in the savings banks have increased. He believes increased deposits indicate greater poverty. I can only say I beg to differ in opinion, but will not argue the point, nor will I question but there are large numbers of persons who work for very low wages. I only maintain that, upon the whole, wages are far in excess of what they were during the present generation.

In giving details of advances made in the commerce, education, and comfort of the nation I include other classes besides those who pawn their coats and petticoats every Monday.

B. R.

COMPOUND NON-CONDENSING ENGINES.

[26376.]—I have carefully read the letters of "Engineering, Manchester" and "Ingeniero" on this subject. With regard to the tandem engine, I agree with "E. M.," as it has several advantages over the simple engine irrespective of mere economy in coal. As pointed out by "E. M.," the strains on the crank-shaft and framing are greatly reduced by compounding, while the first cost is very favourable as compared with the ordinary compound engine with cylinders side by side. The latter, however, is more economical in fuel, and this I attribute to the more uniform turning of the crank-shaft. Still, very good results as regards economy of fuel and water have been obtained from the tandem engine, and it is by no means a class of engine to be despised, a large number being at work both on board ship and on land, giving every satisfaction. In reply to "E. M.'s" inquiry *re* compound locomotives, I think quite enough has been said on this subject now. It has been most conclusively proved that they are greatly inferior to the normal locomotive in every respect, and until some further develop-

ment takes place I see no good in continuing the discussion. Every credit is due to the engineers who have tried them, and we can only regret that the results obtained have not proved more encouraging. **G. D. Seaton.**

THE ADVANTAGE OF STEAM DOMES.

[26377.]—THE results, so far of my attempt to induce your readers to discuss the mechanical arrangements of engines, instead of giving mere lists of locomotives and times of runs, are not encouraging. "A., Liverpool" (p. 84), says I am mistaken when asserting that the use of a dome on a boiler is to increase the area for containing steam, and thinks it necessary to inform me that its use is to prevent priming. As I have not made the assertion it is of no moment; but I pointed out in the very letter that the locomotives which do the fastest work in this country are without domes, and they do not prime. If that is all the dome is for, it may be given up at once. "Kappa," p. 86, thinks he has answered my question by saying he "should think" that sixty miles in one hour is done every day on the G.N.R. He qualifies this "thinking" with a condition which puts it out of court. If there is a train which does sixty miles in one hour—in which a passenger can take his seat and find himself sixty miles distant in sixty minutes—I should like to know where it is to be found. **J. T. M.**

RAILWAY MYSTERY.

[26378.]—I QUITE agree with the opinions expressed by Mr. A. H. Allen (letter 26339, p. 132) with reference to the possibility of a pistol remaining upon a carriage step. Mr. T. Perkins, p. 134, and "Glatton," p. 136, appear to express opinions which are not in accordance with the results of the practical experiments. The moment a pistol or other article is dropped from a window of a carriage in motion its velocity decreases, whereas the train continues at the same speed—therefore, during the time the pistol was falling the train would move forward a certain distance. The wind would, of course, also tend to reduce the velocity of the pistol, and this fact was stated by me in giving evidence before the coroner's jury.

As the case is almost sure to form the subject of litigation, I do not here express any opinion as to whether or not the case was one of murder or suicide, and therefore I do not in this letter deal with the concluding portion of Mr. Perkins' letter.

Clement E. Stretton,
Consulting Engineer Amalgamated Society of Railway Servants.
Railway Congress, Town Hall, Brighton, Oct. 8.

LOCOMOTIVES, &c.

[26379.]—YOUR correspondent "Loco.-Erector" (letter 26352) would apparently have us believe that Mr. Johnson does not understand his business In very offensive terms he contrasts Mr. Johnson's engines with those of his predecessor, Mr. Kirtley. But I should like to know whether it was Mr. Kirtley or Mr. Johnson who made the 800 class what they are—Mr. Kirtley, with his little boiler and 17in. cylinders, or Mr. Johnson, who has now completely rebuilt them, and turned them out a vastly superior engine to what Mr. Kirtley designed?

Has not Mr. Johnson now rebuilt and enlarged nearly all the engines that Mr. Kirtley constructed? and who will venture to say, much less to prove, that he has not improved them? And who can say that Mr. Johnson's own engines are not fully equal to the 800 class?

Out of several hundreds of engines designed by Mr. Johnson, the 1667 class are the only ones against which there has ever been a complaint raised. And these engines are not such egregious failures as some would have us believe. Until the 1740's came out, they worked the Leeds expresses south of Nottingham regularly, with splendid punctuality, on 29lb. of coal per mile. All they wanted was to be worked expansively. With more heating surface and 20lb. more steam they would be as fine engines as there are in the country. They have now gone to Derby to be altered, and when they come out I have no doubt they will answer the expectations formed of them when they were first built.

I should think that a gentleman who has turned out some of the very finest engines in the kingdom deserves the title of a *thorough engineer*, and I think the Midland Company has enough sense to fully appreciate his services.

If your correspondent thinks otherwise, I would ask him to compare the locomotive stock of the Midland Company now, with what it was when Mr. Johnson first went to Derby, and I think his doubts will very soon be set at rest.

"Engineer" (letter 26317) asks why no engines can be built now to equal the 800 class. I should like to know in what points any of Mr. Johnson's engines are inferior to them.

Do not the 1560 class pull the same trains between Skipton and Carlisle on a far harder road, as the 800 class pull between London and Skipton?

If "Engineer" will first prove that the 800 class are the best engines on the line, it may be worth while to discuss why; but till then any discussion on the subject would be out of place.

Rugby Oct. 8th. **E. A. Speed.**

[This must end the discussion, which, as unfortunately has been the case so many times lately with correspondents about railway engines, &c., has become absurdly personal.—ED.]

PLATELAYERS.

[26380.]—INTERMINABLE discussions continue on the subject of locomotives, their various types, capacities for work, and a vast amount of technical detail is brought forward, which is almost Greek to one not an expert. When you are borne along in an express train, perhaps by night, at the rate of 60 miles an hour, it must occur, of course, that your safety is primarily in the hands of the engine-driver who has charge of the train; and, secondly, of the various signalmen along the line. Doubtless the responsibility of engine-driver and signalman is most serious and weighty.

But it must not be lost sight of that the safety of the train equally depends upon the rails—a deficiency in the gauge here, or a bolt loose there, might be the cause of a train plunging off the rails to immediate destruction. Over all the many miles one may travel by railway, every inch almost of the permanent way must be in thorough order, and we therefore think the work of the platelayer is equal in responsibility to that of the engine-driver or signalman.

It would be interesting to have some details from some of those correspondents acquainted with the subject, about the work of platelayers. What is the average distance of the line one would have under his supervision; how often inspections are made, and the *modus operandi* of replacing a rail, which is rather a rare operation for an ordinary passenger to witness? Is this latter, on crowded lines, generally done in the night, when the traffic has virtually ceased for a few hours?

Oct. 10th. **E. E. M.**

LAUNCH ENGINES.

[26381.]—IN reply to Mr. W. H. Taylor (letter 26348, page 133), my opinion is that in adding a large cylinder to the two 6in. cylinders no beneficial results will be obtained; in fact, I firmly believe that the additional cylinder would be a drag. I have only had to do with two engines of this class, viz., in which the two h.p. cylinders exhausted into one l.p., both of which were a failure. It is the usual custom in a compound engine of this type to place one h.p. between the two l.p. cylinders. The reason this class of engine is made is, that when very high pressures are used it would necessitate a very large l.p. cylinder; consequently, by using two the areas may be reduced, the initial loads on the pistons are reduced, and the engine will run much smoother at slow speeds, on account of the power being distributed over the three cranks. But it has this against it: The friction of the three cylinders is greater, also the extra cost in making, and more space is occupied than the double crank compound. Another class of 3-cylinder engine is coming to the front—the triple expansion—this has a low pressure, medium pressure, and high pressure cylinders. To work this engine with success, it is necessary to expand the steam down to 8lb. to 12lb.; it has been found that this is the type of engine for very high pressures, such as 120lb. and over.

In your case, I would suggest your placing two 3in. cylinders on top of the 6in.; that is, if it is your intention of compounding. Then, again, assuming that you compound them in the 3-cylinder style, the engine would be too small to obtain good results.

In opening this discussion on the compound non-condensing engine for launches, I never anticipated that compound surface condensing engines would be brought against it; but of every 100 launch engines I have no doubt that 99 will be found high pressure, and in preference to these I advocated the compound non-condensing engine. There is not the least doubt but that the compound surface condensing engine is far superior as regards economy, and would do away with the evil of exhaust; but, as I mentioned in a previous letter, the extra cost and weight would be against it for small boats. The compound engine with outside condenser has been advocated. I know nothing of their efficiency; but I believe that a few of the steam pinnaces in the navy had them, and have given up using them for some reason or other; for myself, I like to see everything connected with a marine engine above board, and easy to get at.

Engineering, Manchester.

VIBRATION.

[26382.]—I NOTICE that it is thought much of that a flame will reply to the fundamental and harmonics of the voice and musical sounds. Perhaps it will interest our fellow-readers to know that the filaments of a pigeon's feather will *vibrate* the same. I do not say they will cause a sound for me to hear, as I have not a delicate microphone or telephone to test. A suitable feather will also vibrate any fundamental sound. If a certain supply of inked sand is made to rest on the point, the inked sand will be scattered according to the pitch of the note, and as it falls on a damp unrolling slip of paper, registers the sound. This small instrument was shown at the Inventions Exhibition (Stand 3707) by me, 1885.

T. Wood.

THE NEW APOCHROMATICS.

[26383.]—IN my paper on the new apochromatics, which you do me the honour to publish in your last issue, I observe one or two errors, and would esteem it a favour if you correct these in your next issue.

1st. On page 127, centre column, 40 lines from foot, read *num. aper.* instead of "mm. aper."

2nd. On page 127, end column, in table of apochromatic objectives read *focal lengths* instead of "screen distances."

3rd. The heading of the second table should be thus:

Screen distance of the objective 250 mm.	Search oculars.		Working oculars.				
Focal lengths	1	2	4	8	12	18	27

Kindly make these corrections.

Paul Schulze.

LATHE MATTERS, &c.

[26384.]—THE melancholy fate of useful appliances when made up after discussion or review in our columns, of the which "O. J. L." makes us aware, appears to me to be largely due to the depression in trade. Those who would purchase cannot, and are necessitated to get along with such appliances as they already possess. Some are in advance of and some unfitted to the times, and amateurs generally, I think, have a preference for their own schemes and a belief in their capacity to improve on any extant appliance—thus they become hesitating buyers.

Novelties have also to contend with vested interests in the form of other appliances and apparatus to produce them, as well as with prejudice, conservatism, or indifference.

The phrase "Survival of the Fittest" is an abbreviation responsible for a pretty complete and general misunderstanding of the natural law of selection. "Survival of the fittest *to the conditions*" is the proper expression, whereas the abbreviation implies, and is generally understood as meaning, the "survival of the fittest *to survive*"—a result or action of which the natural law is almost entirely innocent. That pills, toothpicks, penholders, and other "inventions," and trashy novels, &c., are more profitable and approved than things of sterling merit, simply shows that such are better adapted to existing conditions; the "remnant" is not the million. It is Zadkiel's and not the "Nautical Almanac" that sells. Which would the Hottentots prefer—beads, bangles, and rude weapons, or a Cremona?—fetishes and charms, or the appliances of science?

I have never been able to see the supreme difference in merit that the Patent Law decrees between two inventors, both of whom have brought the same invention to practical perfection—the loser having perhaps spent the more time, labour, and money, and being the more elaborate and careful, and the only difference between whom is an hour or so in the time of filing their specifications. The "telephone case," for instance. And how much might have been done, compared to what has been done, if right, justice, and "survival of the fittest to survive" had always ruled?

I like "F. A. M.'s" headstock, and should like also to see the rest of the drawings. A few suggestions might be made as regards the headstock. The inner portion of the front traversing bush is exposed. It would be better covered, the cone being moved back, if required. To allow the bushes to turn is desirable, and if headstock was properly made in a full workshop, could be done; but I doubt if tools or abilities of most amateurs would be equal to the task. The splits would require a piece of paper or wood between them after cutting, to keep grit from oil grooves, &c. The unusually large face and centring would be difficult and expensive, according to present ways; but if adopted and attempted, might be managed more easily than expected. If mandrel were cut after spring-tempering throughout, the face and centring would be easier to get true than if hardened after shaping closely, but the internal thread would be difficult to cut nicely. The large internal centring would be apt to come in contact

with the heads of screws; but if cut a little nearer centre than slot holes, the defect would be avoided. There appears to be room, in case spring-temper mandrels were used, for a hardened ring to be inserted and form the centring, attached with sunk screws, half and half into ring and plate, the ring being a pretty tight fit, and ground to truth and size after fixing.

I do not quite understand the traversing gear. In the explanation of the mechanism the "traversing handle" is called the "reversing handle," I think, and is spoken of as proceeding from *the strap* of the eccentric. This would result in a capacity to rotate the star-guide only. To throw it in and out of gear, it would be necessary to fix the handle, the traversing handle, with the tooth on it, on to the eccentric itself. Adjusting collars might be put behind the mandrel pinion to take back-thrust, and render cones more easily fitted by the less skilled, as the shoulders might be omitted.

Vulcan.

LATHE MATTERS.

[26385.]—"F. A. M." is to be congratulated on the good solid ground he has given us to work upon after our rather long pause. The general features of the design he gives us appear able to take care of themselves; but some of the details seem open to discussion and capable of improvement. To ease reference, I will number my remarks.

1. The reverse carriages on slide-rest are common in clock and small lathes, and are suitable for light cuts; the increased leverage, or overhang, on the V's renders the arrangement unsuited to heavy work. For working up to face-plate they are handy; but for general work, especially near centres or loose-head, they are less convenient than the more usual style, as the slide requires a clearance equal to its length plus its movement, instead of its length alone; in fact, they are awkward, and apt to foul the loose-head and such work as cranks, &c.

2. The vice-screw would be apt to catch clothes and sleeves, and there is not room to reverse tool to tail side of box, as is sometimes desirable; the rest seems designed for a "mandrel" rather than a lathe for working to fast-head only.

3. The slip or gib seems out of place under the tool: it is less solid than if on other side; the box could not be "set," or nipped up after setting tool, as two of the screws are covered by it; it would be unhandy when near face-plate, and if horizontal set-screws were used they would be left-handed to screwdriver.

4. A ball-turning arrangement might be fitted to saddle, but there would be little difficulty in doing so.

5. The collar on lead screw is a good device where screws are stiff and short; but in long screws when thrusting, nuts at the tail end lend a valuable tensional resistance to bending. A plain collar, about one diam. long, with set-pin in a groove —to prevent it turning—and a fit on shank, should precede nuts where a good result is needed.

6. The clasp-nut is on a neat mechanical plan; but a defect in connection with it is that it is fitted to one end of saddle only; the screw would get worn locally, and about a foot at tail end would not be used at all. The remedy is either two nuts, or to make the one movable from end to end, as then a little manœuvring with top-rests would wear the screw pretty evenly.

7. The gib at bottom of saddle is about in its best place; wear could be taken up, or, in case of local wear, bottom V of bed could be scraped up, without affecting general alignment. The bulk of the wear would come on this V, as it takes the weight and down thrust, but the saddle tending to come outwards, would be checked by top V, so I should suggest a more acute angle on top, and less acute one on bottom V—a rather obtuse angle on the latter.

8. From the height of centres, the V's look a trifle close together, and for metal work they would be none the worse for the support of a temporary V, or a counterweight, at far side of bed, and on horizontal saddle, or temporarily-fixed arm.

Vulcan.

STATIC ELECTRICITY—CHROMIC ACID.

[26386.]—IN reply to "A., Liverpool" (26344, p. 132), there is no difference in principle between the two editions of my "Electricity." The second is an extension of the first, taking up additional branches and describing the various advances of the science; but the whole of the first edition is wholly reproduced. I do not think more than 20 pages were cut out in the process of reconstruction, though the matter was differently arranged; therefore all I said on p. 107 applies, though my quotations were taken from the second edition. However, the greater part of them will be found on pp. 40 and 41 of the first edition, in the very description of the muslin bag experiment to which "A." refers. At the end of § 47 it is distinctly stated "If an interior body is provided, through which the circuit is completed, then electricity is to be found in the inner surface." The matter is also fully explained on the next page.

As to the other matter of the glass and rubber, "A." will never get a clear comprehension as long as he holds to the absurd notions of an electrical fluid or fluids, and talks about their trying to join each other. It is all clear enough when we study the action of the whole circuit instead of one part of it only. The resistance to discharge is in the air and the glass. The tendency to discharge is not at the point of contact of glass and rubber. The stress in the opposite direction is set up there, as it is in the valves of a pump; but there is no more tendency to discharge them than there is for the water in the pump to run back.

The other experimental observations of "A." in like manner are explainable by the simple laws of the induction circuit, in which static stresses correspond to the motions of the conduction circuit in which current occurs.

In regard to the remark of "Mag. est Ver.," p. 135, I will look up the question and see what I have to say. I may say now that some time ago I spent a week over some very full experiments on chromic acid; but pressure of other occupation has prevented me from working them into the form of an exhaustive article or two, as I intended. I suppose I shall manage to complete the work before long.

Sigma.

PHYSICAL BASIS OF LIFE.

[26387.]—WHETHER the following details will in any way supply the information inquired for by "No Sig., Paris," No. 26345, page 133, I am unable to say; but having long pondered on the fact of coal being permeated by sulphuret of iron, and in many cases blended with it, at the close of 1859, when reading M. Pouillet's "Eléments de Physique Expérimentale et de Météorologie," I stumbled on the Solar System, and when I came to "l'ellipse brillante" of Saturn's ring I paused, and frequently repeating the word "brilliant," it flashed to my mind that that ring must contain the gas of a metal, and, if so, it may be the source of our iron-beds, which in their construction correspond to those of coal and of salt, none of which are accounted for by geology, which branch of science is remote respecting the formation of our ocean and atmosphere.

We are told by Prof. Huxley, in "Physiography" (1882), both by word and sketch, that the roots of the plants of the coalbed period are invariably in the underclay, and as the seams of coal are very numerous, whilst the intervening rocks are, as we are told, of ocean formation, it does not exactly appear how the protoplasm for the production of the vegetation of the several seams or beds found its way into the mud or clay.

If, however, as it occurred to me in 1852, we contemplate the Solar System as being simply the means devised by the Creator by which to prepare an abode suitable for the reception of man, on the evidence of facts we find that geologically every orbit has assigned to it its share in the production of that abode, and the rungs of the ladder, after all, are not so very much opposed to those of Jacob. The sun, then, being a highly incandescent body, is surrounded by an atmosphere electrical in proportion to the incandescence, but decreasing with distance, and the approach of all the "planets" to that luminary at the rate of the diameter of their respective orbits will account for the changes they are respectively undergoing; hence the change in our climate—afterglows, earthquakes, &c., but more especially the chop seas instead of the round waves of 60 years ago.

The number of orbits, so far as we are aware, is nine, four on this side of the asteroids—those troublesome bodies to the astronomer and period of creation—and four on the other side: and allowing the positive or *cold* condition of the sun's atmosphere to cease with the orbit of man, that on the other side must necessarily be hot or negative in proportion to distance; and granite, it is said, has been subjected to heat, although "of deep-sea formation." I need scarcely state that the matter of the rock, &c., is in the respective orbits, and that the rocks themselves, so beautifully disposed in layers, are of nebulous formation —the orbits of Neptune, Uranus, and Saturn being of the primaries, terminating in the coalbeds; Jupiter the secondaries, Bath and Portland stone, saltbeds, reptiles, and cretaceous. The water of the North Atlantic and all other waters are as gas in Saturn, whose atmosphere extends to his outer ring, and as vapour in Jupiter's atmosphere, the crust of the north being formed as a belt round the Equator by centrifugal. The orbit of the Asteroids is divided into rings, the Wealden being the first evidence of fresh water, there being a geological break after the Cretaceous; so that it would appear that during this unaccounted-for period there prevailed an enormous vegetation to the production of the beds of lignite and our atmosphere, followed by the antediluvians of the Eocene and Miocene periods, when the belt was broken up by change of inclination to the Sun, and the antediluvian mud was sent to the North, forming Siberia and New Siberia, which collection of bones, &c., terminates at the Gulf of Obi. The Pliocene I conceive to have followed the disturbance above referred to, and to have been the period of the creation of the present race of animals, the post of honour being that of man; after which our planet passed from the Asteroids into the orbit of Mars, when the earth covered the whole surface of the planet, the orbit of Mars being the Compressing period (when were formed the gigantic convolutions that have so much engaged the attention of scientific men) preparatory to the formation of the bold headlands that were to resist the influence of the present disturbed ocean. I need scarcely state that all th protoplasm or germ matter came from above, and this closes the Forming period.

Chertsey, Oct. 11th. **F. T.**

LEGAL REPLIES.

[26388.]—SHARE CERTIFICATES (60593.)—A shareholder is (1) a subscriber to the memorandum of association, or (2) a person who has agreed to become a member, which is done by an application for shares followed by allotment. Every shareholder is entitled to a certificate of his shares upon payment of the nominal fee. In this question both classes named have become shareholders, and, therefore, they should have certificates; but these certificates will show what is paid upon each share, and will leave the holders liable for the rest of the share should they be called upon, or should anything happen to the company.

LEGAL MARRIAGE (60616).—The English Courts will recognise as valid a divorce of an English marriage granted by the courts of the foreign country in which the parties are then domiciled. But the English Courts would not admit the validity of a divorce granted in America at the instance of one party while the other was domiciled in England, and the fact of such an application by a wife would not legalise the husband's second marriage in England.

LIFE POLICY (60635.)—If money is lent upon a life policy it should be done by way of mortgage, and a proper deed of assignment drawn up, giving the borrower a power of redemption on repayment of loan, and providing for the application of the policy moneys; the payment of interest, the production of receipts, &c., and notice given to the insurance office. Compound interest cannot be claimed unless expressly agreed upon. If no proper mortgage is made the lender may have some trouble afterwards in enforcing his security.

Fred. Wetherfield, Solicitor.
2, Gresham-buildings, Guildhall, E.C.

A RECENT number of the *Japan Weekly Mail* contains a short account of a night ascent of the active volcano Asamayama. The party left Karnisawa in the afternoon, and commenced the ascent from the eastern side about sunset. The sky was perfectly clear, and the summit was reached an hour before midnight. The wind, blowing from the south, carried the sulphurous vapour away to the northwards, and thus the ascent was made less uncomfortable. The party saw quite to the bottom of the crater, which presented the appearance of a furnace filled with glowing coals. The sound of the roaring, hissing, and bubbling is described as loud and awful. The walls of the crater are of a light-brown colour, and are composed of successive layers marked out with striking regularity, like the seats of an amphitheatre. Allowing ten of these layers to each interval of 20ft., the depth from the surface to the incandescent matter would appear to be 200ft. The periphery of the crater is about half a mile, although the Japanese calculate it at two miles and a half.

Tobacco Growing—A correspondent writing to *Notes and Queries* with reference to the cultivation of tobacco in Yorkshire a hundred years ago, says:—Now that there seems a prospect of English-grown tobacco becoming a marketable commodity, it is interesting to call to mind the fate of a previous attempt. In and about 1782 many acres were sown with tobacco in the vales of Pickering and York, the greater quantity in the latter. In the Pickering district the growers were not molested, and in the richer parts a considerable quantity was grown and properly cured and manufactured for the pipe and pouch by a man who had been employed in an American plantation. But in the Vale of York the tobacco was publicly burnt, and the growers were severely fined and imprisoned, penalties being laid, it is said, to the amount of £30,000. This not only put a stop to the illegal cultivation of tobacco, but also stopped the cultivation of the limited quantity (half a rod) allowed by the law for purposes of "physic and chirurgy." It was applied in farming to the cutaneous disorders of cattle and sheep.

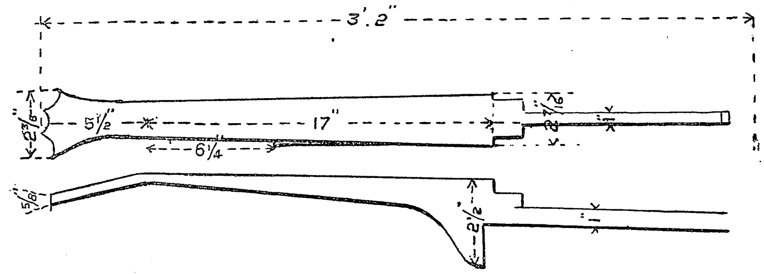
REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[60049.]—**Silica.**—To "SOUTH AMERICA."—If "South America" will send me a small sample of his silicious earth, I may perhaps be able to give him the information he requires. For my address please consult the Address Column.—P. HOLMES.

[60186.]—**Mathematical.**—To "E. L. G."—I took the size off the drawing-board as 9·4in., but here is the working:—The side x of the cube $= \frac{6 + 6\sqrt{3}}{\sqrt{3}}$, or $2\ (3 + \sqrt{3}) = 9{\cdot}464$in.—T. C., Bristol.

[60275.]—**New Banjo.**—Taking up your query, the vellum would be drawn down between if you screwed far enough; but it is little more than drawn over the inner hoop. I hope Fig. 1 will explain. The inner hoop must be very strong, and certainly ought to be thicker than the outer hoop or pan, as it is called. A 12in. hoop will be best. I



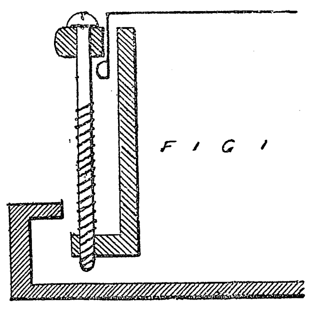


FIG 1

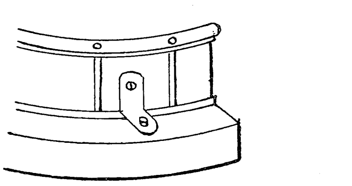
FIG 2.



send sketch of a staff for 12in. hoop; but you don't say how many strings, so I have left out the width of nut. You must allow ¼in. for each string; thus a 7-string banjo will be 1¾in. across the nut. Note that the inner hoop is to be made complete, the staff fitted to it; then the pan is put on, and held in its place by brackets, shown in Fig. 2. It is known as the Dobson banjo, and I advise you not to start on brass until you have overcome the difficulty of tightening the vellum without having to remove the pan. If you get into difficulties with your brass one, and would like to make a silver one of the latest pattern, I shall be glad to help you.—SAM KOE.

[60296.]—**Black Stain for Wickerwork.**—It is doubtful if anything cheaper than logwood and copperas can be found; but surely this is a matter for experiment by the querist.—NUN. DOR.

[60306.] — **Photographic Engraving.** — To discover the reasons for this querist's failure it would be necessary to have the book referred to and personal experience of the manner in which he carried out the instructions. Further, it is not easy to understand what is meant by "etching it wholly by mechanical means," for etching, which I believe comes directly from the German ätzen, implies the eating out of parts by means of acid.—SAML. RAY.

[60312.]—**Lubricating Oil.**—I do not think "J. B. G." will find any test of the kind he requires; but he should read the article on p. 496 of the last volume, and look through the indices. Something may, of course, be done with the spectroscope; but I know of no published experiments in that direction.—F. I. C.

[60316.]—**Electric Time Ball.**—I thank Mr. Glatton for his suggestion in answer to my query; but it would not be applicable to my case. I want the ball to rise suddenly about six minutes to each hour. I should be pleased to hear from E. Conry, or any practical man.—WATCHMAKER.

[60317.]—**Specimen Fish.**—The art of stuffing fish is one of the most difficult branches of taxidermy, and it would be useless to attempt its explanation in any detail. The fish is usually turned with its worst side uppermost, and a cut made along the sub-dorsal or lateral line, having previously covered the other side with thin paper, which will readily adhere to the scales, and keep them in position while the flesh is removed from the back. There are several manuals of taxidermy to which the querist may be referred.—ESOX.

[60323.]—**G.W.R. Outside Eccentric Engines.**—"G. N. R." asks for what purpose the eccentrics are placed outside on the engine which has since been illustrated on p. 90. I presume he knows that it is a common practice on the Continent, and that it is done to get more room for the cranks in the axle and the slide-valves, and also because the motion can then be more easily examined and oiled.—J. T. M.

[60324.]—**Terrestrial Telescope.**—A pancratic eyepiece is an ordinary four-lens eyepiece which permits the distance between the two pairs of lenses to be increased. Without examination it would be impossible to say if your glass was worth the alteration. My glasses were made by Dallmeyer.—EDWARD M. NELSON.

[60334.]—**Falling Bodies.**—If the track of a body falling through the earth is an ellipse, as "E. L. G." states, then its angular slope from the plumb-line will be at a maximum directly it is let fall, for at that point the tangent to the curve is at right angles to the major axis (i.e., to the plumb-line), and the angle will continually diminish until the extremity of the minor axis is reached, where it will be nothing, the tangent being parallel to the major axis. However, "Dubliniensis" says that the body starts along the vertical, and if this is the case the curve cannot be an ellipse. I do not see the utility of prolonging this discussion, for several assumptions as to the density of the earth have to be made, some of which we know to be incorrect, while we have no means of verifying others. Moreover, no two correspondents agree in their figures, the time required to fall to the centre of the earth being given as 20 minutes by one, and half an hour by another, and the velocity of passing the centre as 5 miles and 3½ miles per second, while another asserts that the body is retarded by the portion of the earth's crust behind it!—R. E. F.

[60334.]—**Falling Bodies.**—Suppose a stone capable of falling freely through the body of the earth were dropped from the surface at the Equator, it would have, at starting, an eastward velocity of about 1,525ft. per second, and since we are supposing the earth homogeneous, and are neglecting the slight disturbance of the problem caused by the fact that the earth is an oblate spheroid, the stone would be attracted towards the centre of the earth with a force proportional to its distance therefrom, and it would describe an ellipse, with its centre at the earth's centre. The axis major of the ellipse would be the diameter of the earth, and the axis minor would be twice the above 1,525ft. $\div \sqrt{\mu}$; μ being the attractive force at unit distance from earth's centre, or g the gravitation at earth's surface; $\div$ R, the earth's radius. Calculating from the numerical values of these, we shall find that said axis minor would be about 520 miles—that is to say, the stone would miss the centre of the earth by the half of this, or about 260 miles. When abreast of the centre, if we may so speak, the stone would be very nearly that distance away from the well bored through the centre of the earth to the opposite side. It is easy to see, by drawing the ellipse, which would be stationary, and considering the rotating well in connection with it, that the stone would be still increasing its distance from the well until it had reached the opposite side of the earth. The above 260 miles may be depended upon; it is easy to see, without calculation, that the distance must be pretty nearly that.—DUBLINIENSIS.

[60352.]—**Fire-Engine.**—Sorry to say I can't oblige "J. K." without more particulars, as S. and M. make many different sizes. Was it a vertical, single, double, or triple? If at a fire-station, where?—SAM KOE.

[60410.]—**Electro-Motor.**—To MR. THOMSON.—Length 36in., 9in. beam, 6in. deep, and 4in. deep in water. As I have not got the boat with me just now, I cannot tell you what weight it would take to sink it, because I have never tried. It is made of wood. I have got bichromate cells, chloride of zinc, and Bunsen cells, all pints.—ROCHDALE.

[60421.]—**Carriages — Railway Mystery.**—It is amusing what a controversy has sprung up on this apparently simple point. Without presuming to instruct "Glatton" or the others, may I remark that the wind would have remarkably little practical effect on such a body as a pistol, which would offer no resistance. The action of gravity, of course, would not have the least effect on the position of its fall, merely tending to pull it straight down, while *vis inertiæ* would tend to carry it on, being set in motion by the train, and, therefore, it would fall nearly under the window, as Mr. Perkins points out. There is no reason why it should move while on the foot-board, when once it got there, more than it would inside the carriage on the floor, barring the wind, which would have little or no effect.—R. A. R. BENNETT.

[60430.]—**Gravity Daniell Battery.**—To "WEALD."—Read my reply again. In using plain water to charge the zinc, where do you suppose the acid comes from which acts upon the zinc, if not from the copper sulphate? Free acid is formed in the cell as follows: Zinc and sulphuric acid form sulphate of zinc and hydrogen. The hydrogen so formed passes on towards the negative plate; but on reaching the sulphate solution is exchanged for copper, which, in turn, is deposited on the surface of the negative in the form of metal. This action transforms the sulphate of copper $CuSO_4$ into sulphuric acid H_2SO_4, and unless a reserve of crystals is kept to reinforce the solution, nothing but free acid will remain. You say that the solution contains free acid, per test paper. Then what need had you to ask from whence it came? Perhaps the above will make all plain to you; if not, you had better consult "Thompson," "Guthrie," "Sprague," or some authority, in preference to an "A.S.T.E.," as although the letters look imposing, the privilege of using them does not depend upon the amount of knowledge the individual may possess, but entirely rests upon the payment of one guinea per annum.—C. D. R.

[60432.] — **Architecture, &c.**—Among the books to be recommended, I would mention Fergusson's "History of Architecture," Stuart and Revett's "Antiquities of Athens," Tarn's "Geometry for Architects," Haskell's "Architect's Guide." With regard to the contemporary history of architecture, I should think that the most useful thing for "Upsilon" would be to consult the criticisms, expressed in torrents of execration, on Mr. Street's designs for the New Law Courts, which appeared in the public press. Let him see the *Builder*, Dec. 2nd, 1871, and March 30, 1872, the *Times*, August 19th, and Dec. 6th, 1871, the *Illustrated London News*, Sept. 23rd, 1871, and March 30th, 1872; also the attacks of Mr. Fergusson in Macmillan's *Magazine*, Jan., 1872, and in *Builder*, July 1st, 1871. As for special articles in periodical literature, I would refer "Upsilon" in particular to "Classic and Gothic Architecture," dispassionately considered by G. Wightwick, in *Builder*, March 1st and 15th, 1862; "A Fight against Gothic," by Alex. Thomson, in *Builder*, May 19th, 1866; a Lecture against Gothic, by the Hon. Cavendish Bentinck, in *Builder*, Feb. 24th, and March 3rd, 1877; also, "Have We a National Style of Architecture?" in *Builder*, Sept. 10, 1859. Architecture at the present day is labouring under a terrible incubus in the shape of the so-called Gothic Revival, which is causing our new buildings to be erected with hideous deformity, a galling air of monkish austerity, and the utmost inconvenience of plan. This is chiefly due to the action of some superstitious old women who have such a superstitious veneration for the remains of the Middle Ages that they insist on having our new buildings made in exact reproductions of those ancient edifices, and presented in one hotch-potch of such reproductions. The present mania in England for this Gothic patchwork has made our architecture the laughing-stock of the whole world, but it is only a passing fashion. Gothic—which is the monkish architecture of pre-Reformation times—is quite

inadequate for secular buildings; it cannot present unity of effect; it cannot afford convenience of plan. There is nothing to approach the majestic simplicity, the proud bearing, the dignified solidity and symmetry of Classic. But leaving aside architectural appearance, there never was such an atrocious failure in point of practical requirements —since the Tower of Babel—as was the new Law Courts, a building which does not even admit the light of day. We see also that the stonework of the Houses of Parliament is already falling fast into decay, so that they cannot remain as a lasting monument for future ages, and yet any common stone-mason ought to be able to test the durability of stone by simply trying its resistance to the action of fire. Such miserable and deplorable mistakes as these are due to the fact that the designs and plans for Government buildings are selected by one or two members of the Government who generally have no natural faculty for architectural discernment, nor any knowledge of the practical work of building.—DELTA.

[60453.]—**North British Engines.**—Dimensions of 592 class are: Cylinders, 18in. by 26in. Wheels—bogie, 3ft. 6in.; driving and trailing, 7ft. Boiler—length of barrel, 10ft. 3in.; diameter, 4ft. 5in. Heating surface—tubes, 980 sq. ft.; firebox, 110 sq. ft.; total, 1,090 sq. ft. Wheel base of bogie, 6ft. 6in.; of driving and trailing wheels, 9ft. 3in. Weight in working order, 45tons 9cwt. For working drawing and illustrations see the *Engineer* Sept. 17th and Oct. 8th.—E. A. SPEED.

[60454.]—**Wind Motor for Electric Lighting.**—I am afraid that I shall not be able to comply with "C. D. R.'s" suggestion at present; but I think I may promise that a full description of the motor shall appear in the "E. M." before very long.—J. G. GWYNT.

[60462.]—**Testing Lightning Conductors.**—The testing of the upper part of lightning conductors is simply humbug. For example, suppose that 11 strands out of 12 strands of No. 16 B.W.G. lightning conductor are broken, continuity would be maintained by the single strand; its resistance would be so low that no instrument would be capable of detecting it. The only way of testing the upper part of a lightning conductor is to periodically examine it. The "earth" may be tested in the following manner:—Connect one pole of a battery to the water supply and the other pole of the battery to a shunted galvanometer, the other pole of the galvanometer to a resistance box, thence to the lightning conductor. Open no resistance in the box, and adjust shunt until you get a deflection of, say, 30°; now open resistance until that deflection is halved: the resistance inserted will then equal the resistance of the battery, shunted galvanometer, line, and earth.—EDWARD M. NELSON.

[60484.]—**Twilight.**—My data last week seem to have got considerably mixed up. The distance apart of the two circles = circular measure of 18° × earth's radius = ·31416 × 3,956 = 1,242 miles. The actual distance is about 1,172 miles. In speaking of the "two *great* circles," I did not use the word in a technical sense, for it is evident that two great circles cannot be parallel to each other.—R. E. F.

[60484.]—**Twilight.**—The statement of "F.R.A.S." on p. 130, that "there is no doubt that twilight not only should, but does, last 72 minutes at the Equator," comes opportunely as authority for what "R. E. F." objects to. I had said only "nearly 70 minutes," because, if it ends (as generally allowed) when the sun's zenith distance is 108°, day does not end till his true zenith distance is 90° 50′—namely, 90° + his semidiameter + the horizontal refraction. It is not twilight, but day, as long as any of the sun's disc is visible above a sea horizon. He has only to descend 17° 10′ between that and the depression 18°, so that I cannot make the shortest possible twilight exceed 69 minutes, nor the width of the zone thereof exceed 1,200 statute miles. I must leave "R. E. F." to his own diagram to find that his line $a\,x$ necessarily cuts off double of this if inclined 18° to the horizon at a. If he means that to be a place where the sun is depressed 18°, and this line to point to the sun, x will be a place where he is elevated 18°. If the twilight zone were of the width he says, we could have no hours dark in London in the months of April, May, June, July, August, and half September! The shortest Equatorial twilight, too, he would make 141 minutes, while telling us there are places where it is but 15. Where, and according to whom? It does not end, moreover, at the "first sixth-magnitude star" appearing, but the faintest ones, and not at the zenith, but near the N. or S. horizon. Those in the east or west may be dimmed by zodiacal light when proper twilight is quite absent. "R. E. F." will find me as bad as "Libra" for persisting in "errors" that happen, like his probability calculus, to be more correct than peculiar.—E. L. G.

[60491.]—**Time.**—There are several ways by which "Chronos" might find time to rate his regulators. Star transits are, of course, the best and most accurate method; but for their observation they require a transit instrument with a telescope of at least 2in. in aperture on a very firm pillar, and in an apartment isolated from housemaids and their dusters. This puts star transits out of the category of "simple methods" which "Chronos" requires. Another very excellent method is an observation of the sun with a sextant and artificial horizon: a mean of five good sights of the sun when not less than three hours from the meridian should give you the time to one second. This method is simple enough. The objections to it are the time and trouble it takes, and it requires an assistant to note the times. Another method is by a dipleidoscope. It is an instrument for taking a meridian observation of the sun. It is very simple, but requires to be thoroughly well fixed. The best plan would be to bolt it to a stone pillar in the garden with a suitable cover to protect it from the weather. The simplest and best of all is a meridian sundial, of which Fig. 1 is a side view.

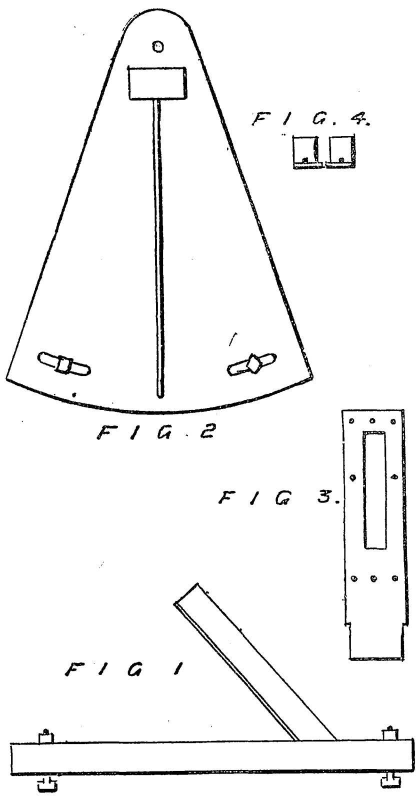


FIG. 4. FIG. 2. FIG. 3. FIG. 1.

It should be made of gunmetal, and should be bolted to a massive stone pillar which is set on a good foundation. Too much importance cannot be placed on the quality of the foundation. I have noticed that a great many sundials are inaccurate from want of attention to this point. The gnomon should be inclined to the base plate at an angle equal to the latitude of the place. Fig. 2 shows a plan without the gnomon. Slots are cut at the wider end for the bolts to pass through and allow for final adjustment. On the lower side of the gnomon a thin plate is screwed, having a vertical slit $\frac{1}{25}$in. wide. Fig. 3 shows the gnomon with the plate removed, and Fig. 4 shows a section of the gnomon with the plate fixed. The base plate might be 11in. long, and the gnomon 6in. The metal should be $\frac{1}{4}$in. thick, or, in any case, not less than $\frac{3}{16}$in. The meridian lines on the base plate should be very clearly ruled and be $\frac{1}{20}$in. apart. Time should be found with this dial to five seconds. Although not so accurate as some mentioned above, it will, I have no doubt, suit "Chronos'" purpose; at any rate, it fulfils his condition—viz., that of simplicity.—EDWARD M. NELSON.

[60503.]—**Photography.**—Mr. T. Perkins, replying to this query, is very inaccurate. He says: "Mr. S. Bottone, replying to this query, is very inaccurate." Now, as a matter of fact, Mr. Bottone did not send the reply quoted by Mr. T. Perkins. It was sent by a much better man than I—namely, Mr. R. A. R. Bennett. Surely, Mr. Perkins, if it pleases you to throw stones, you should be careful about your own glass house, and be quite sure you are *quite correct.*—S. BOTTONE.

[60503.]—**Photography.**—In case Mr. Bottone may be inclined to regard himself as a hardly-used mortal, after Mr. Perkins's remark, I hasten to take my sins upon my own shoulders, and to remark that it was not he, but I, that wrote the answer referred to. It is certainly gratifying to a humble individual like myself to be taken for such an authority as the gentleman above mentioned. As to the plates, I can answer Mr. Perkins that I know as much about them as he does, at any rate; the full explanation being that the "Ilford" plates now, and the "Britannia" plates a few months back, are one and the same. In consequence of a lawsuit between Harman and Marion, the name of the plates has lately been changed to "Ilford," and they are now manufactured by the "Britannia Works Company"; while Marion's present name of "Britannia" is a different make. If Mr. P. can get "German" and "Ilford" plates for 1s. per dozen, he may congratulate himself—I can't. Marion's old "Britannia" ("Ilford") plates were advertised at 1s. 6d.—R. A. R. BENNETT.

[60510.]—**Mathematical.**—If the origin be at the centre, then r cos. θ is the ordinate of any point in the periphery of the circle whose radius is r. Let all the cosines be drawn in a quadrant, so that any two adjacent ones have a perpendicular distance a between them, and let a be extremely small; then the area bounded by any two adjacent cosines, the periphery and the radius, is expressed by $r \times \cos.\,\theta \times a$, and the sum of all these small areas between 90° and 0° is the area of the quadrant, or $\frac{\pi r^2}{4}$; hence, $\sum_{0^\circ}^{90^\circ} r \cos.\,\theta \times a = \frac{\pi r^2}{4}$; and if n is the number of spaces or elementary areas, then $n\,a = r$, or $a = \frac{r}{n}$; wherefore, $\frac{r^2}{n} \sum_{0^\circ}^{90^\circ} \cos.\,\theta = \frac{\pi r^2}{4}$; but $\sum_{0^\circ}^{90^\circ} \cos.\,\theta$ is the average value of the cosines in the quadrant, and each side of last equation being divisible by r^2, we get average value cos. $= \frac{\pi}{4}$.—G. H. H.

[60511.]—**Boys' Marbles.**—It does not quite appear, from the account "J. K. P." quotes, how they become so accurately spherical. There is doubtless a trade mystery in the process. We used to buy some about a third the diameter of his, I think, in white marble for ½d., and in agate (or perhaps pale flint) for 2d. apiece, these last with a polish equal to glass. Now, it strikes me that, whatever way those were made, smaller ones of glass, clear quartz, or even garnet or zircon, ought to be producible, and being afterwards split, each piece could have a plain side wrought, and then serve for a lens, either for microscope or telescopic eyepiece. The boxes of "J. K. P." fully illustrate the waste of room I said must be involved if the border balls of a layer be in contact, as he seems in every case to put them. The number in his first; the cube of 8in., I suppose a misprint for 512, each internal ball touching only 6 others. If each layer were a honeycomb layer, it would be 68, and the box would hold 544, each touching but 8 others. But by making these layers alternately of 68 and 67, he will find depth for 9 of them, or 608 balls; each interior one touching 10 others. Of course, that still wastes room compared with natural piling, where each touches 12; but it is probably the most that his arbitrarily chosen size of cube will hold. Indeed it only needs $8 \times 7{\cdot}93 \times 7{\cdot}93 = 502{\cdot}9$ cubic inches. What he means by his No. 4 being "closer packing" than the others, I cannot tell. Its 11 equal layers, of 64 each, require $8{\cdot}5 \times 8{\cdot}5 \times 8{\cdot}0711 = 583{\cdot}2$ cubic inches, whereas No. 2 is but $8 \times 8 \times 8{\cdot}0711 = 516{\cdot}6$ cubic inches, and putting 629 balls into this, I make rather closer than putting 704 in the larger box. But now compare either with the cube of $1 + 5\sqrt{2}$, which holds half of $(11^3 + 1)$. The cubic inches are $151 + 265\sqrt{2}$ = not quite 525·8; holding 666 balls. It adds but 9·2 cubic inches to "J. K. P.s" No. 2, to admit 37 more balls. Again, his No. 4 has to augment it no less than 57·4 cubic inches for only 38 more balls.—E. L. G.

[60512.]—**Mathematical.**—I think "R. E. F." has rather missed the point of this query. We are required to solve the simultaneous equations $a = x^2 + y$, $b = x + y^2$, which means that we have to find x in terms of a and b, and y in terms of the same symbols, such values to satisfy both equations. From the first we get $y = a - x^2$, and from the second $y = \pm\sqrt{b - x}$. Equating these two values of y and squaring, we get an equation of the fourth degree between x and a and b, which if solved would give four values of x, and a similar equation in y would give four values for y; but as it is a troublesome business to solve a bi-quadratic the following will be found easier, especially if numerical values be given to a and b. We have $a - x^2 = \pm\sqrt{b - x}$, the term on the right may written $\pm\sqrt{b}\sqrt{1 - \frac{x}{b}}$. Now, take the square root of $1 - \frac{x}{b}$ and we get

$$a - x^2 = \pm\left(1 - \frac{x}{2b} - \frac{x^2}{8b} - \frac{x^3}{16b} - \text{\&c.}\right)\sqrt{b}$$

Now, if a and b are each not less than unity, we

must have a or b greater than y or x, consequently $\frac{x}{b}$ must be a proper fraction, and as the squares, cubes, &c., of fractions diminish rapidly, especially when divided by increasing denominators, the term involving x^3 and those following may be omitted for the present at least, and thus we get a quadratic equation in x, or rather two equations. Owing to the double sign each of these will give two values of x, so we get four values, and from these the corresponding values of y may be found. If further accuracy is required substitute the values thus found in the term involving x^3 and solve the quadratics again, and thus any degree of accuracy may be obtained.—M.I.C.E., Bath.

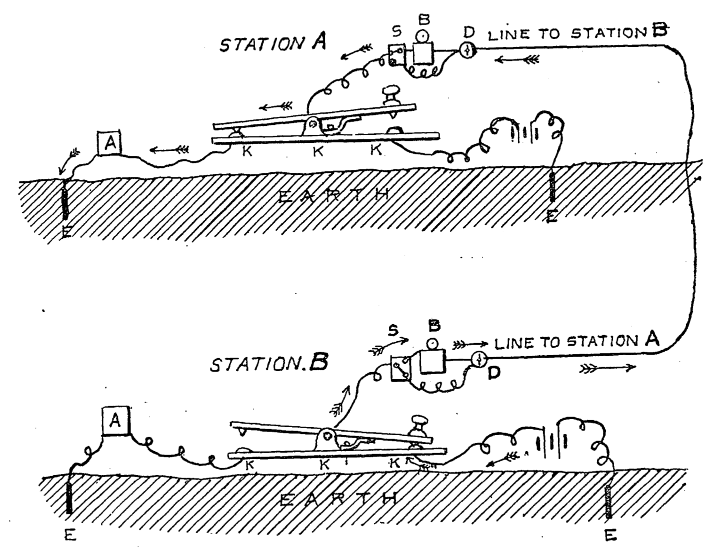
[60513.] — **Pianoforte Repairs.** — TO MR. DAVIES.—The keys cannot be taken out of a grand piano without first removing the hammer-frame; this may be done by taking out the screws or nuts at the ends and middle, when the frame may be lifted clear of the hoppers. In loop actions the process is more complicated, as each loop must first be unhooked from the spring and pulled through the hopper; in replacing the frame, the hammers should be kept clear of the hoppers by a straightedge, which may rest on each end of the frame. It will be rather tedious to rethread the loops, but a little patience is of as much value as experience in matters of this kind. Take your time, and do not get flurried or use force: if any part does not drop easily into its place, see what is stopping it before you exercise pressure. A little undue haste may break some of the delicate mechanism which would probably be out of your power to repair. If, as is most likely, the keys are bushed, the key-pins will be of an oval or cricket-bat shape, in which case the sticking may be eased by turning the oval of the pin more parallel to the key. If this is done with pliers the surface of the pin should be protected with paper, as a roughened key-pin would make an unpleasant grating noise and soon wear through the cloth.—W. H. DAVIES.

[60518.]—**The Starry Heavens.**—To "FELLOW OF THE ROYAL ASTRONOMICAL SOCIETY."—"Cœli besse tenus liceat convexum tueri." Thanks for your reply to the above query in the "E.M." of October 9th, p. 130, and also as to the Latin, which is not mine—certainly not the "infinitive" of the verb. I did not write tuera, which is purely an error of the printer. It is now nearly fifty years ago since I had anything to do with Latin.—ONE NOT AN ASTRONOMER.

[60525.] — **Bewitched Barometers.** — E. B. Fennessy seems to be one of the numerous class of people who look upon barometers as rain indicators, whereas a barometer simply tells the weight of the column of air above it; and this, I do not doubt, his barometer has continued to do faithfully and truly. As a rain indicator a barometer is only useful when read in conjunction with other things, such as the direction of the wind, the appearance of the sky, the amount of moisture in the air, the temperature, and the readings of other barometers at a distance. A great deal of the misunderstanding with regard to barometers is due to the practice of the makers in putting on the scale such words as very dry, dry, change, rain, much rain, which really have little or no meaning. It is quite possible by carrying a barometer up a mountain to change its reading from very dry to much rain, though the weather may be all the time perfectly fine, and likely to continue so. Let E. B. Fennessy observe other atmospheric phenomena, in addition to that one which the barometer indicates, and he will then find that, although he may not be such a dogmatic weather prophet, he will, on the whole, be a truer one.—BUNTING.

[60540.] — **Tricycling Matters.** — "Gamma Sigma" inquires why small geared-up wheels on tricycles give better results than large level-geared wheels? He has raised a question which has been discussed a great deal in cycling papers, and the great majority attribute it to decreased weight and windage; but, in my opinion, though they do make a difference, they do not make all the difference. I think the secret lies in their revolving at a greater rate, and on that account overcoming resistance more easily, especially up hill and against the wind. Then, again, the wheels being smaller, they throw less strain on the framework on account of their decreased leverage. With respect to the automatic steering, that is giving way to the "stuffing-box" system, which causes the steering-wheel to turn stiffly; the automatic steering was found very trying when not riding in a direct line.—G. TOWNSEND.

[60549.]—**Telegraph Connections.**—TO E. CONRY.—A, single needle telegraph; K, key, for sending: the axis of lever must, of course, be insulated from the two contacts on the stand. B, bell, S, two-way switch for putting bell in circuit or cutting it out; D, a simple low-resistance detector, or galvanometer, for indicating that the current is passing and the circuit therefore complete. This last is not absolutely indispensable



(as two bells will ring in series, though not well) but it is a better arrangement to have it in. A small compass with a few turns of wire round it will do. There is a battery at each end. When the telegraph is not in use, the bells are left switched on. When you ring to station B, you cut your own bell out for the instant, and directly you stop ringing switch it in again, so as to receive the answering ring of station B, who similarly cuts his own bell out, leaving it out until the completion of the message. These switches can be made by contacts above and below the lever, if you like it to be a better arrangement. You then cut your own bell out and send through A, by means of the key, the "Are you there?" (three raps), if there is any possibility of anybody but your regular correspondent being at the other end, to which he replies by two raps, and you then proceed to send your message. If there is a regular attendant at the station B, and no one else is allowed to touch the instrument, the "Are you there?" may be dispensed with. A similar signal, four raps answered by three, or any other you may arrange, marks the end of the message, when you and station B both switch your bells in, and leave the apparatus till next wanted. There are two batteries you will observe. With a line of the length you mentioned, I should use four cells at each end—they need not be large, the smallest Leclanchés made would do. If you experience any difficulty in getting your bells to ring with the four-cell battery, owing to not having specially wound telegraph bells, you can arrange another switch so as to leave A cut out, until wanted, like the telephone connection. The P. O. has special keys which do all the switching work automatically, so to speak. The lever is metal, with metal points—these and the contacts preferably of platinum.—E. CONRY.

[60554.]—**Charging Accumulators.**—It is very difficult to tell, merely from the quantity and gauge of the wire, what current a dynamo will give, as so much depends on the make; but even with the best make, I should think it would take you a long time with such a dynamo as you describe, to charge any cells, on account of the very little current. Cannot you get an actual measurement by ammeter or tan. galvanometer of what your machine gives.—E. CONRY.

[60557.]—**Honours Exam. in Electricity.**—TO S. BOTTONE. — Procure J. T. Sprague's "Electricity;" also S. P. Thompson's "Electricity and Magnetism." Join the City and Guilds or the Birkbeck classes, and try to repeat every experiment given in the two books mentioned above. Take written notes of every experiment, and do not be satisfied till you have thoroughly understood the why and wherefore of every one. By next May you will be ready for the exam. You must keep yourself in the swim with all electrical novelties, and must know mathematics.—S. BOTTONE.

[60560.]—**Water Wheel.**—There would be no theoretical difference in the velocity of the water, and the inclined trough is the best arrangement as things are; but the wheel should have been larger to utilise the fall. It is the weight of water and fall utilised, not the impact, which represents so much loss.—T. C., Bristol.

[60560.]—**Water Wheel.**—Yes; the position C B would be better, because you would thus add the force of gravity of a falling body to the impetus of the water. The A B position, however, might be advisable where you had a strong head of water on, and depended on this head or jet power for your force. Where there is no more head than will about make the water run freely, C B would be best, making the distance C D as great as possible. —E. CONRY.

[60561.]—**Polish.**—If "Colombo" has access to Vol. XLIII., July 9th, he will find several good recipes for polishes by "Nun. Dor." that will suit his purpose.—T. H. G.

[60561.]—**Polish.**—What does this querist mean by a good and cheap polish, as he does not wish to varnish? A polish is a varnish, and properly applied costs a great deal more than varnishing. French polish is made by dissolving shellac and gum benzoin in wood naphtha (say 3oz. shellac, ½oz. benzoin to the pint of spirit), and a good brush polish, which I suspect is what the querist requires, may be made by mixing two parts of French polish with three parts of the ordinary brown hard varnish of the shops. If either of the above is used on black work it will be as well to crush up a bit of Prussian blue, and put in it, so as to bring up the black of the stain.—SAML. RAY.

[60562.]—**Current Quantity.**—The intended process is impossible, and any answer in this direction wholly misleading.—SIGMA.

[60562.]—**Current Quantity.**—The size of the zinc has absolutely nothing to do with the number of ampères. This depends on the resistance of the fluid and the size of the negative element, together with the resistance of the interpolar.—S. BOTTONE.

[60562.]—**Current Quantity.**—Cannot be done by the method you propose; there are other considerations beside the surface of the zinc, viz., strength of liquid, surface of negative, distance of zinc from carbon, &c. You must calibrate by means of a standard instrument.—C. D. R.

[60562.] — **Current Quantity.**—You cannot calibrate any ammeter that way with any serviceable degree of accuracy, as different batteries vary in the size of plate producing a certain current, and the same battery will, for a certain number of sq. in. immersed, give different amounts of current at different times, according to the state of the solution and plates. The only way that I know of by which you can get any good results in calibrating by current of primary batteries is to get a large Daniell cell, or, better still, a Latimer Clark's standard cell, which, you know from the size of the C. plate, gives more than some particular quantity, say one ampère, but ½ or ¼amp. will do. If I remember rightly, a well-made Daniell cell takes about 22 sq. in. of Cu immersed to produce one ampère. Then get from some instrument-maker a couple of standard resistances as 1 ohm and 2 ohms; but it does not matter what they are so long as they are known and accurate. For convenience, one should be about double of the other. By means of these you can construct a Wheatstone's bridge, and with this apparatus measure off any resistance you want, and since the Daniell gives practically just 1 volt E.M.F., and you know from the size you have more than, say, 1 amp. current, you can obtain from it any proportions of current you want; by Ohm's law $C = \frac{E}{R}$, and, as you know, E = 1 volt and R = what you have measured it to be by the bridge, you can get C, as, for example, with R of 1 ohm 1 volt will put exactly 1 ampère through. The Wheatstone's bridge is not at all difficult to make, and having once made it, roughly, but accurately, by its means and the Daniell you can calibrate a tangent galvanometer, by which in turn you will always be able to calibrate ammeters so long as you use the tangent galvanometer in the same town or part of the country.—E. CONRY.

[60563.]—**Lathe Speed Pulleys.**—You do not give distance between centres of crankshaft and mandrel, which affects size of grooves; but if you require to use a single gut, 12in., 13in., and 14in. on the wheel will be near about. The tighter you make your gut beyond a certain point, the harder the lathe drives, and with ordinary tension and depth of grooves, no difficulty should be experienced in changing from one speed to another when lathe is moving slowly.—T. C., Bristol.

[60566.]—**Relief in Photo. Negatives.**—There is no method of "drying the plate and preserving the relief." The only thing to do is to take photographs in such a way that there will be the quantity of relief wanted by "Sepia" on them when dried. Use plates with thick films, under-expose, develop with a double quantity of pyro, and you will get relief, or contrast, which is the same thing.—B.Sc., Plymouth.

[60569.]—**G.E.R. Locos.**—No. 538 is an 8-wheeled goods engine of the Mogul type. Principal dimensions are: Diam. of leading, driving, and trailing wheels (coupled), 4ft. 10in.; wheels of pony truck, 2ft. 10in.; cylinders (outside), 19in. by 26in.; total wheel-base, 23ft. 2in. Heating-surface: tubes, 1,291 sq. ft.; firebox, 102 sq. ft.; total, 1,393 sq. ft.; grate area, 17·8 sq. ft.; weight in working order on pony truck, 8tons 10cwt.; leading wheels, 12tons 11cwt.; driving, 13tons; trailing, 12tons 11cwt.; total, 46tons 12cwt. The engines of this class were built by Neilson and Co., and are Nos. 527—531, 1878; and Nos. 532—541, 1879.—EAST ANGLIAN.

[60570.]—**Burning Oil.**—If you try to use your pipes for paraffin oil I am afraid you will regret it, as you are sure to have a mess from the oil working through the joints, however tight they may be, to gas, and a very little of that goes a very long way. If I used any pipe at all I would use compo, with as few joints as possible; and, after all, nothing would beat a small cistern with a tap to fill lamps from as required.—T. C., Bristol.

[60571.]—**L. and N. W. Locos.**—No. 2082 is not a compound, unless City of Liverpool now bears that number. There are 30 Dreadnoughts on the line now.—E. A. SPEED.

[60573.]—**Lighting Schoolroom.**—There are cheaper lamps made on the same principle as the "Bower" and "Wenham,"—the "Furness," for instance, is, I think, less than half the price. It is difficult generally to get a bell-mouth ventilator fixed above each burner and still have the neat appearance that everything in a schoolroom ought to have. Would not a large fret-work covered ventilator in the ceiling do better?—I. LOW.

[60574.]—**Astronomical Photographs.**—I am not aware that the photographs of the Orion Nebula and the Pleiades by Messrs. Common and Henry respectively can be purchased at all. I have only seen them myself at Burlington House, in the R.A.S. library. But probably Mr. Sadler would be able to give "S. R. C." some definite information respecting these marvellous examples of the photographic art. As to photographs of the moon, those by Rutherford (about 11in. diameter) can be obtained from Mr. Brothers, of Manchester. The price *was* 7s. 6d. each; but possibly they may now be sold at a cheaper rate.—W. S. FRANKS.

[60575.]—**Bichromate Battery.**—To MR. BOTTONE.—Yes, retort carbon will do. Saw it in slabs with an old saw, sand and water. See No. 1,117, p. 561, of the "E. M.," for illustration and description of kind of battery required, under the heading "Wonderful Lamp." One cell is enough.—S. BOTTONE.

[60575.]—**Bichromate Battery.**—Any pot or jar, with a zinc and a carbon plate in it (retort carbon will do, with clamp binding screws, screwed hard on to it, or the end copper-plated and the binding screws soldered to the copper, and the latter painted with Brunswick black or paraffin wax) within the jar a solution of 3 parts bichromate, 1 part sulphuric acid, and 6·6 parts water. A very small battery, with only a few square inches of acting carbon, will do for a medical coil.—E. CONRY.

[60575.]—**Cheap Bichromate Battery.**—To make a cheap bichromate battery procure a marmalade jar 5in. deep by 2½in. diameter at the top, also two plates of carbon (without terminals) each 5in. by about 2in., and a zinc plate of the same size. Amalgamate the zinc thoroughly, and solder a binding-screw at the top. Cut two pieces from a cigar box, 3in. long and ½in. broad. Place the two pieces of wood to the right and left of the top of the zinc; place the two carbons to right and left of the pieces of wood, and fix this arrangement by means of a clamp binding-screw, which becomes the carbon terminal. When the cell is in action the plates are in the usual bichromate solution in the jar, supported by the projecting ends of the pieces of wood. When not in use lift the plates out. Retort-carbon would do, if one had the patience to cut it. Should the querist try it, however, and succeed, the binding-screw is attached by being soldered to copper, which is deposited at the part where the connection is made.—BOBADIL.

[60576.]—**Faulty Bell.**—The fault is in the bell itself; it requires to be adjusted. Examine the tip of contact screw, and see that it is clean; also ascertain if the spring is corroded at the point of contact. Both the screw and spring should be tipped with platinum, and if they are not, corrosion is sure to take place. See also that the spring is sufficiently strong to bring the armature away from the magnet after contact is broken.—C. D. R.

[60576.]—**Faulty Bell.**—No. 2 is corroded, probably from the air of the surgery being infused with drugs, as that of a surgery generally is. In No. 3 the cores of the magnets have not been properly softened, and should be taken out and heated, and re-softened in lime thoroughly. Put the armature closer to the ends of the cores by means of back screw, the spring of the bell seems weak, or else the battery is, which you can judge of by the way it rings the other bells. I suppose you have either a three-terminal bell or else some switch in the line O, as in the drawing the battery would be short-circuited through No. 3 if it is an ordinary bell.—E. CONRY.

[60578]—**Lathe.**—The pulley would be keyed to shaft, or made to revolve with it in some way, and would be used for obtaining a low speed of mandrel without back gear. An ordinary tap will cut the thread in wood for chucks.—T. C., Bristol.

[60578.]—**Lathe.**—The loose wheel does not appear to be of any use as it is: tighten it upon the shaft and you can use it for slow speeds; you can cut a thread in a wooden chuck with a tap. It can be obtained at most tool shops where tools for metal are sold. If your mandrel-thread is of Whitworth gauge, all you need do is to measure the diameter with a pair of calipers, and get a tap of the same dimensions.—C. D. R.

[60579.]—**Lathe.**—Scarcely a job for a beginner; but if the bed is very bad—so very bad—you can see what you can do with a file towards making it true.—C. D. R.

[60579.]—**Safe.**—Of course. Get a straight-edge and file and work away. If bed is only "fairly" true make it quite true, or you will soon be disgusted with it.—T. C., Bristol.

[60580.]—**Paquelin's Thermo-Cautere.**—"Vet. Surgeon" is under a mistake in thinking that "the price charged is out of all bounds." I have Collin et Cie's list before me, and the price for the apparatus complete is only 125 francs (£5). I have often thought while using it that it was one of the cheapest instruments used in surgery. The price of the cautère cylindro-conique, which is the platinum part oftenest used, is 35 francs (28s.), and "Vet. Surgeon" couldn't possibly make it for this. The maker's address is 6, Rue de l'Ecole de Médecine, Paris.—B.Sc., Plymouth.

[60584.]—**Blueing Steel without Heat.**—The only way to blue steel without heat is to coat it with a blue-coloured lacquer or varnish. The question has often been asked, and is an essentially stupid one, as it is cheaper to blue steel by means of heat than by lacquer which needs a skilled hand to put it on properly.—NUN. DOR.

[60585.]—**Laying Pipes.**—Only ordinary stiff clay, used as dry as it will work. A little oil is sometimes used with the lead to prevent spattering; some pour the oil in the joint.—T. C., Bristol.

[60585.]—**Laying in Cold-Water Pipes.**—A clay that will make good red bricks is the sort used for lead jointing. It is made smooth, pliable, and tough by constant kneading: no oil is used.—B.Sc., Plymouth.

[60586.]—**Wimshurst Influence Machine.**—To "INDUCTION."—So long as the ebonite keeps its insulating quality it will answer in place of glass. It is not easy to say where you are wrong; but from what you state it is possible you may not have the plates turning in the proper directions. Remember, the front plate should turn in the same way as the hands of a watch. The back plate must turn in the opposite direction. Another cause may be that the supports to your collecting combs are of imperfect material, and the electricity may escape away by them. Test them for insulation. It is better to have all four brushes in metallic contact with one another; but omission in this respect will not prevent the machine from working.—J. W.

[60587.]—**French Button Lens.**—Is a single achromatic lens, consisting of a double convex crown and plano-concave flint. Three of these are generally mounted together in three little brass discs, and screwed together. They cost in Paris about 6s. the set, and the lower powers are really excellent. I have one by me now, which cost me 10s. mounted. It is a good ¼in. o.g., and the photo-micrographs which were published last year in the *Photographic News* were done by it. I would not sell it for ten times its cost, so good is it.—S. BOTTONE.

[60589.]—**Laminated Armature.**—Provided you buy the patent punchings from the patentee or his agents, you may use the laminated armature without risk. I shall be happy to procure some for you, if you will write to me. (See advertisement in Sale Column). They should be mounted on a steel spindle, and extend the whole length of the F.M.'s. The armature can be supplied without the other parts. You are right in supposing that the magneto-machine would require a commutator to rectify the currents. This is also required if it is to be used for incandescent lighting. The armature also would need to be wound with coarser wire than when used for "shocking."—S. BOTTONE.

[60591.]—**Hardening Spring Steel.**—Heat your springs to a bright red, plunge into water. Then rub on some oil, and again carefully heat. The moment the oil flares drop your spring into water again, and it will be correctly tempered. Of course, the great point is to heat your steel uniformly in both heatings; otherwise it will be hard in one place and soft in another.—HENDON.

[60591.]—**Hardening Spring Steel.**—Some rub a little tallow on the spring after hardening, and then draw it backwards and forwards over a clear fire until the grease catches light, and it is allowed to burn a longer or shorter time (and quenched), according to nature of steel, which is found by testing a piece off each bar.—T. C., Bristol.

[60593.]—**Share Certificates.**—They can only be issued to those who have paid the sums due on the shares. People in the conditions stated are liable to proceedings to make them pay up.—SIGMA.

[60593.]—**Share Certificates.**—In neither case given by "Secretary" can a certificate be issued. In the first case (A), an allotment letter should be sent, or rather a letter in that form, with the additional intimation that the application money is still unpaid. In the second case (B), the usual allotment letter is all that can be issued. Forms are to be found in Pulbrook's "Handy Book of Joint-Stock Companies," 2s. 6d.—B.Sc., Plymouth.

[60594.]—**Model Yacht.**—If "Amateur Yachtsman" would care to write to Norie and Wilson, 156, Minories, London, E.C., and inclose 4s. 6d., he could procure a very good book on model yacht building by T. E. Biddle. I have made a successful model myself from his instructions.—H. K. F.

[60595.]—**Geometrical.**—If I understand the query rightly, there are four straight lines given, and the positions of the first two lines are fixed. On each of the given straight lines construct a rectangle having for its second side the line which is to be perpendicular to the first. Then, where the sides of the rectangles opposite the given lines intersect, will be the point required. If the positions of the first two lines are fixed, there can only be one such point, and very often no point at all; but if not, then there are any number of points.—R. E. F.

[60596.]—**Pump.**—I have seen some made of vulcanite throughout, and should think this would answer.—T. C., Bristol.

[60597.]—**One Side of Room Dark.**—If room has a dark-coloured paper, replace this by one having plenty of white ground. Or you might try a large screen covered with white paper placed (at an angle) opposite the window. If this does not reflect sufficient light, cover the screen with tinfoil, and if that will not do, place a mirror in the corner.—HENDON.

[60597.]—**One Side of Room Dark.**—Put up a mirror, or an article of furniture having plenty of mirrors, opposite the window, but slightly angled, so as to reflect over to the middle of the left-hand wall; from there, by mirrors or silvered plate door bookcase, reflect the light to the right-hand dark corner.—B.Sc., Plymouth.

[60597.]—**One Side of Room Dark.**—An ordinary mirror the height of the window, and about 18in. wide or more, will, if placed at the side of the window, deflect the rays of light and spread them like a fan all over the room, except just the part adjacent to the opposite side of the window. If mirror is unavailable, bright sheet-tin will make a good substitute, and even a board covered with white paper would be a help.—E. CONRY.

[60600.]—**Musical Intervals.**—The ratios in the major scale are—

Do	Re	Mi	Fa	Sol	La	Si	Do_2
1	$\frac{9}{8}$	$\frac{5}{4}$	$\frac{4}{3}$	$\frac{3}{2}$	$\frac{5}{3}$	$\frac{15}{8}$	2

and a little investigation will show that there are in this scale three kinds of intervals:

(1) $\frac{9}{8}$ between Do-Re; Fa-Sol; La-Si.
(2) $\frac{10}{9}$ between Re-Mi; Sol-La.
(3) $\frac{16}{15}$ between Mi-Fa; Si-Do_2

According to Ganot, the two first intervals are called tones; but Blaserna calls $\frac{9}{8}$ a major tone, and $\frac{10}{9}$ a minor tone, which seems better than using the same word for two distinct ratios. Similarly Ganot terms the interval $\frac{16}{15}$ a semitone, and thus makes no distinction in name between it and the interval $\frac{25}{24}$, which he also calls a semitone. Blaserna uses the terms "major semitone" and "minor semitone." The magnitudes of the intervals are best represented by the logs of the ratios, thus—

Major tone	·0511526
Minor tone	·0457574
Major semitone	.0280287
Minor semitone	·0177288

The term "limma" to denote the ratio $\frac{16}{15}$ seems peculiar to Deschanel. It may occur in Stone; but I cannot refer at present.—WM. JOHN GREY, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[60600.]—**Musical Intervals.**—Deschanel has given the only three diatonic ratios there are, and it is equivalent to saying that eight-ninths of the string which sounds Do (all other conditions being equalised) will sound Re, nine-tenths of the string which sounds Re will sound Me, and fifteen-sixteenths of the string which sounds Me will sound Fa, and so on, the first interval being a major tone, the second a minor tone, and the third a limma or diatonic semitone. Why are there two kinds of tones? Because the major third which contains them shall have the simple proportion of four to five with the keynote, and $\frac{8}{9}$ of $\frac{9}{10} = \frac{4}{5}$. In the same manner a minor third of five to six contains a major tone and a diatonic semitone for $\frac{8}{9}$ of $\frac{15}{16} = \frac{5}{6}$. The minor tone is the quantity required to complete a major third, and the diatonic semitone that required to complete a minor third when a major tone has already been taken. Now, two diatonic semitones are somewhat larger than a major tone, and considerably larger than a minor tone; hence the term semitone is a misnomer. Thus fifteen-sixteenths of the string sounding Do will sound Re flat, and fifteen-sixteenths of this will sound Me double flat; so that $\frac{15^2}{16}$—that is, $\frac{15}{16}$ of $\frac{15}{16}$, or $\frac{225}{256}$ of Do sounds Me double flat, which is two diatonic semitones from Do. But the $\frac{8}{9}$ Re takes $\frac{227\frac{5}{9}}{256}$ of Do, and a $\frac{9}{10}$ Re grave would take $\frac{230\frac{2}{5}}{256}$ of Do, and the intervals left by the minor tone and major tone are smaller than that left by the two diatonic semitones. I do not see where your difficulty lies if you can deal with vulgar fractions, unless you are trying to reconcile the true musical intervals with those of the equal temperament keyboard of the piano, organ, harmonium, &c., where two equal temperament semitones make an equal temperament tone, and 12 make a just octave. If so, you must entirely dissociate these totally distinct matters. It has been justly remarked that these tempered intervals are but a rough approximation to the true intervals, none being correct with the exception of the octave, the errors in slow movements being very palpable.—S. E. HUNT.

[60601.]—**Battery.**—Cannot be done economically by battery power; you want a dynamo.—C. D. R.

[60601.]—**Battery.**—Five or six Smee's, gallon size; about a fortnight. But why not use a small plating dynamo?—S. BOTTONE.

[60602.]—**Aquarium.**—Did you take particular care in your experiments to remove everything of a decaying nature as soon as you discovered it? I think many animalcules would naturally die at the expiration of a month or two. I have kept some alive for a long time with plenty of growing weeds in the water, planted in well-washed gravel, and the glass put in a strong light. If the green algæ grew all over the sides of glass, they ought to do well. The best weed is *Anacharis alsinastrum*, the "American water-weed," which thrives apace.—R. A. R. BENNETT.

[60607.]—**Polishing Photo. Frame.**—Polish with rottenstone and oil, and lacquer. Many recipes for brass lacquering are to be found in previous numbers.—B.SC., Plymouth.

[60607.]—**Polishing Photo. Frame.**— You can clear it with sawdust and weak nitric acid; when clean and polished, paint it with brass-o-line—a new fluid manufactured by Mr. Birtwhistle, of Burnley, Lancs. This prevents all brass coated with it from getting tarnished again. It does not show in the slightest degree.—R. A. R. BENNETT.

[60610.]—**Fluorine.**—TO "L."—Where did you see the statement that this element had been isolated?—WM. JOHN GREY, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[60610.]—**Fluorine.**—The following is a reply to this query; but as to a description of the element, all that can be said is that it is a gas. What sort of description does "L." require? The element known as fluorine is chiefly remarkable from the fact that it is the only known element which forms no compounds with oxygen. It has an intense affinity for hydrogen, and is extremely difficult to obtain in a separate condition. M. Moissau having prepared anhydrous hydrofluoric acid (HF) by a method due to M. Fremy, submitted it to electrolysis in a platinum U-tube under the action of 50 Bunsen elements. Hydrogen was given off at the negative pole, and at the positive pole a gas was obtained which had the following characteristics: In the presence of mercury it was rapidly absorbed with the formation of proto-fluoride of mercury of a clear yellow colour. In contact with water the latter was decomposed with the formation of ozone. Phosphorus was inflamed with the formation of two fluorides of phosphorus, sulphur was melted with rapidity, carbon seemed to be unaffected, melted potassic chloride cools with disengagement of chlorine; and lastly, crystallised silicon takes fire and burns with great brilliancy upon contact with the gas, forming silicic fluoride. The platinum-iridium electrode forming the positive pole was much corroded, the negative electrode was not attacked. M. Moissau prefers for the present to reserve his opinion as to the exact nature of the gas he has obtained, pointing out that although the most obvious supposition would be that it consists of pure fluorine, yet at present the evidence is not conclusive. It may, for instance, turn out to be a perfluoride of hydrogen, or some mixture of ozone and hydrofluoric acid. It will be noted that the gas differs from that previously taken for fluorine in its action upon silicon.—F. I. C.

[60614.]—**Electro-motor.**—TO MR. BOTTONE.—Yes, you could use your dynamo as a motor, but you would probably find it "reversed" if wanted afterwards to use it as a dynamo. Six quart bichromates would work it to the full.—S. BOTTONE.

[60616.]—**Marriage.**— An American divorce would not affect an English marriage unless both parties became American citizens. Such a divorce and consequent marriage would render the wife liable to a prosecution for bigamy if she came to England, and would be good ground for the husband obtaining an English divorce; but it would in no way unmarry him here.—SIGMA.

[60616.]—**Legal Marriage.**—A divorce obtained in the circumstances detailed by "Subscriber" can never be recognised in this country, and I question very much if it would be legal in America where granted, seeing that the husband is English, the marriage English, and the husband remains in England. If this husband marries again while his wife is still alive (unless he first obtains a divorce in England), he may at any time be prosecuted for bigamy.—B.SC., Plymouth.

[60617.]—**Electric Light.**—I do not recollect the battery you refer to, my last volume of the "E. M." being at the binder's. When it is returned I will look my reply up; but I do not think you will get a battery to last four months with one charge, and work it for six hours every evening; at least, I am sure I never described such a cell—I only wish I could. We should hear very little about Upward's, Schanschieff's, and the Regent battery then.—W. HOLDER (EVELINE), Newport, Mon.

[60618.]—**Tainted Lard.**—Wash it well in hot water several times, and sell it for lubricating purposes.—NUN. DOR.

[60620.]—**Bells.**—Best wire would be No. 26. Sketches of continuous ringing bells have frequently appeared in these columns. You will find one on p. 523, Vol. XLII. (No. 1,091 for Feb. 19th, 1886) which ought to suit your wants.—W. HOLDER, Newport, Mon.

[60621.]—**Leclanche Batteries.**—Agglomerate blocks are manufactured under a patent. You must therefore purchase what you require; not only so, but you would require hydraulic pressure. The arrangement of a terminal connected to the agglomerate has been tried, and condemned.—C. D. R.

[60623.]—**Dynamo.**—TO I. LOW.—I am very busy just now; perhaps someone else will reply to your questions. If not, I will endeavour to do so in a week or two.—I. LOW.

[60624.]—**Cement or Varnish.**—Why not use tinman's solder?—NUN. DOR.

[60624.]—**Cement.**—The following will probably suit:—Dissolve best glue in boiling water to the consistence of a thin syrup; then stir in wood ashes to thicken it; then add a little bichromate of potash, in the proportion of 1oz. to the half-pint.—W. HOLDER, Newport, Mon.

[60624.]—**Cement or Varnish.**—"Metal" asks for a cement that will stand a heat of 80° C. Try the following:—Five parts of clay are to be thoroughly dried and reduced to fine powder; to this add two parts of fine iron-filings free from oxide, one part of peroxide of manganese, half-part of sea-salt, and half-part of borax. These are to be mixed together thoroughly, and made as fine as possible, then sufficient water added to make them into a thick paste. It must be used immediately after making. After application, expose to heat, which is to be gradually increased. The cement will become very hard, and resist heat up to the temperature of boiling-water.—BOBADIL.

[60626.] — **Forming Accumulators.** — TO "SIGMA."—The only way to ascertain the periods inquired about is to watch the lengthening intervals during which charge can be taken in, and to note the results of either reversing or simply charging and discharging. It is a matter varying with the thickness of plates and other conditions, and to be settled principally by judgment and experience.—SIGMA.

[60627.]—**Turning Cotton and Paper.**—I presume these are the compressed rolls used for calendering. If so, an ordinary tool, as used for steel, and rolls driven slowly, say 8ft. per minute. The job takes longer than turning a metal roll same size.—T. C., Bristol.

[60628.] — **Battery Resistance.**—TO MR. BOTTONE.—Because the section of the fluid increases in like proportion, and since the conductivity of a body is directly proportional to the section, it follows that by increasing the section, you increase the conductivity, or lessen the resistance.—S. BOTTONE.

[60634.]—**Safety Lamps in Mines.**—Having taken considerable interest in the question of safe and unsafe lamps for miners' use, I have made some hundred of tests with all the leading lamps in use (over 30 in number) including the Davey, Clanny, Protector, Marsant, Muesler, Bonneted Clanny, Evan Thomas, Gray's, Morgan's (three patents), and other well-known lamps, and I do not hesitate to say, that there is only one really practical safety lamp in existence, that of Mr. Morgan's last invention, which, it is to be regretted, was not patented in time to place before the Royal Commissioners so that the merits and value of this new lamp were duly recorded, as well as the merits of his patent No. 2, upon which the Royal Commissioners in their report say: "We believe this to be one of the safest lamps submitted to our inspection." Mr. Morgan's 1st patent was selected as one of the best for the Lever prize. His 2nd patent won the Gold Medal at the Inventions Exhibition, and is the one now under discussion in many scientific papers. His third patent will win the favour and blessing of every miner who uses it, when its value is known to him. The Morgan testing apparatus is far more severe than that used by the Government, before which there is no lamp but what I can explode in less than ten seconds, except the Morgan lamp, whereas his third patent is better still, and, although I have placed it in almost every conceivable position, I have never yet succeeded in exploding it, although tested to a pressure of over $1\frac{1}{2}$lb. to the square inch with explosive mixture. I have not yet tested the McKinless lamp, so cannot say if it is safe or not; but if Mr. Palmer will send me one, or write me where it can be purchased, I will thoroughly test it and report through the columns of the "E. M." if it can be exploded or not. I should not care to trust my life under ground with some of the so-called safety lamps, which are nothing better than death traps. But with a Morgan lamp I should not hesitate entering the most explosive pit in the kingdom. I trust others who have any knowledge of the Morgan lamp will clearly express their opinions for or against this invention, as the subject is an important one to the community at large.—ARTHUR SHIPPEY.

[60634.]—**Safety Lamps in Mines.**—I was present at the meeting at Leigh, mentioned by Mr. Henry Palmer, and was deeply interested in the experiments there made. The apparatus used by Mr. Morgan, with which he exploded so many of the "safety" lamps in common use, including those most approved by the Royal Commissioners out of the lamps submitted to them, is of a very simple character. It consists merely of a small arrangement of foot bellows, the nozzle of which is inserted in a tube, the further end of the tube being connected with a double jet, so constructed that the air surrounds the inner one entirely, and through which latter ordinary lighting gas is admitted. When pressure is applied to the bellows, air and gas unite at one point in a proportion calculated as nearly as possible at one portion of gas to eight or nine of atmospheric air. Mr. W. Pickard, J.P., miners' delegate for the district, who saw the experiments of the Royal Commissioners, declared at the meeting that Mr. Morgan's experiments were more satisfactory. Certainly, Mr. Morgan's tests were not absolute. He only intended them to be comparative. At velocities much below those liable to be encountered in mines he exploded the Marsant, the Gray, the Mueseler, and Evan Thomas lamps, his own lamp standing the test, and remaining unaffected. The "Morgan" lamp must, in my opinion, supersede all others at present in use, as it yields a better light, and cannot be made to pass the flame. If Mr. Henry Palmer has used the McKinless lamp, he will surely have found that it is not a practicable lamp

in the pit. The Royal Commissioners said of it—"The supply of air to this lamp is very defective; and it is difficult to handle. Mr. Palmer speaks of Mr. Morgan's demonstrations as "a rude awakening." Well, the Commissioners' report was a rude awakening, and thousands of Davy and Clanny lamps have since been discarded. John Woolley's evidence at Leigh also was an awakening. Mr. Palmer thinks Mr. Morgan's success in exploding the four lamps mentioned above in from one to ten seconds a rough comment upon the labours of the Commissioners; but he should have remembered that the Royal Commissioners simply selected the lamps which they considered, on the whole, the best of those submitted to them. As Mr. Morgan stated at the meeting, his lamp was submitted too late, and they could not experiment with it. It, however, won the highest award—the Gold Medal—at the International Inventions Exhibition.—Nemo.

[60636.]—**Painting Magic-Lantern Slides.**—If the dyes are required for colouring photographs, the brighter colours will be required—Oxford blue, Cambridge blue, orange, canary, green, crimson, and scarlet. There is a colour called "cerese." (Why cannot Judson call it "cherry," which is quite as pretty?) This is good for flesh tints when mixed with orange and very much diluted; but as a rule the colours should not be mixed before using them, the most unexpected results being found—for instance, green and one of the reds make blue. All the reds are very powerful, and require much water, and a little spirits of wine to make them flow better. Blues are apt to be weak. If not required for photos, you will require a neutral tint for the shades, or "slate" in the Judsonian vernacular. To begin with, try coating a pane of glass with gelatine, and colour some figure of the church-window order.—M.I.C.E., Bath.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

USEFUL AND SCIENTIFIC NOTES.

The Court of the Shipwrights' Company has just arranged for the delivery of six free lectures to workmen and others connected with the craft of shipbuilding, at the Mansion House, during the Mayoralty of Sir R. Hanson, the incoming Lord Mayor, who is a member of the Company. The following is the list of dates and lecturers:—November 25, Sir E. J. Reed, K.C.B., M.P.; December 9, Sir N. Barnaby, late Chief Instructor to the Navy; December 16, Mr. W. B. Martell, of Lloyd's; January 13 (1887), the Master of the Company, Mr. A. D. Lewis; January 27, Mr. W. H. White, Assistant Controller to the Navy; and February 10, Mr. Elgar, Professor of Marine Architecture at Glasgow.

Cremation.—The cost of cremation at Gotha, according to a report recently read before the Berlin Cremation Society, amounts to £21 10s., exclusive of church fees, singing, bell-ringing, mourning coaches, and urn. An urn may be deposited, free of expense, in the columbarium for 20 years, at the expiration of which term the safe keeping is to be paid for, or the urn will be properly interred, unless otherwise disposed of by the relatives. If the incinerated remains are to be interred in a Gotha cemetery immediately after being cremated, such interment must be paid for like any other; they may, however, be taken away in a tin case by the family if so desired. The quantity of coal required for an incineration, as included in the fore-mentioned specification, is two and a half tons at £1 each. If several incinerations take place on the same day, only one and a quarter tons are charged after the first.

Dr. Lucien C. Rose, of Ohio, has sailed for Gothenburg, Sweden, where arrangements have been made for a public test of his telephone, and his trip abroad is to enable him to be present at the test. Dr. Rose claims to be able to speak and hear with ease and satisfaction with his instrument over a distance of 2,500 miles.

QUERIES.

[60639.]—**Balloons.**—I beg to ask for information as to easiest method of filling (1) paper balloons with coal gas, (2) indiarubber balloons with coal gas. My difficulty with the rubber balloon is that the gas pressure from the jet is not equal to overcoming the elastic compressive force of the balloon.—R. W. C.

[60640.]—**Heating Apparatus.**—I should be glad if any of your correspondents could inform me how, in warming factories by steam pipes, they get over the difficulties of making the pipes rise and fall to pass doors, &c., without the condensed water lodging in the lowest parts. The pipes I presume should be at the bottom of rooms in order to be efficient; but this seems to increase the difficulty with regard to the doors?—A. M. E.

[60641.]—**Horse-Power.**—Will anyone oblige me, if possible, with a rule so that I can determine, by the aid of arithmetic only, the H.P. of engine, the dimensions of which are: pair of direct-acting marine condensing engines, bore, 2ft. $1\frac{1}{2}$in.; stroke, 3ft. 6in., working at 40lb. steam, condensers showing 25in.?—Sam Koe.

[60642.]—**Dynamo Building.**—To S. Bottone, and Others.—I have made a dynamo from instructions and particulars given by "Xero," and have been very particular with every part; no contact anywhere. I have run it all speeds, and tried all ways of connecting up; but have not succeeded in getting a single spark. It will not light either one, a dozen, or twenty lamps. I wound armature with 20lb. No. 12 B.W.G., and field magnets with a total of 60lb. No. 18 B.W.G., double c.c., insulated each layer. Will some brother electrician help me out of my difficulty?—Kent.

[60643.]—**Electrical.** — Would any reader kindly inform me as to the comparative resistance between the armature and field magnets of shunt and compound and series-wound dynamos, or a simple rule to work out the same?—One Anxious to Learn.

[60644.]—**Heating Surface.**—Will any of our kind friends show me how to calculate the number of square inches in a firebox 10in. high by 8in. diam. round firebox?—C. W.

[60645.]—**Faulty Watch.**—I have Geneva watch. It is thoroughly clean, and in beat it goes well in all positions, but will occasionally stop in taking it sharply from the pocket. The only fault I can see is the escapement being too deep. When it is stopped the balance requires moving a considerable distance on either side before there is any drop of escape-wheel teeth on or in cylinder. I shall feel greatly obliged if any reader will kindly inform me how to correct this failing.—F. W.

[60646.]—**Cracked Gongs.**—I have a gong having a crack in it; also two hand bells similarly affected. Can the tone be restored to them, or are they useless? If it is possible to make them ring again, I should feel obliged by someone telling me how.—W. W.

[60647.]—**Music Stand.**—I am about to make a music stand with four shelves resting on turned pillars. If I put the pillars immediately above one another, of course each would only have a hold of half the thickness of the shelves, and I am afraid this would not be strong enough. I shall be obliged if anyone will let me know what is generally done in such cases. If I did not place the pillars immediately above each other, should I put every alternate set inwards at the front and back, or at the sides?—Spes.

[60648.]—**Transparency.**—Could S. Bottone, or any other of the many scientific readers of the "E. M.," kindly tell me a method of making good transparencies from the ordinary gelatino-bromide dry plates? Have a quantity of quarter-plates, which are cut too large to fit my dark slides, so wish to make use of them as above. Have tried contact printing with ordinary pyro-alkaline and ferrous-oxalate treatment, but always get creamy results.—W. W. Railey.

[60649.] — **Low-Resistance Lamp.** — To Mr. Bottone.—I have a small series-wound dynamo, which lights four 5c.p. 8-volt lamps well in parallel. Is it possible to obtain a lamp of 20c.p. which will give a light equal to the four with the above dynamo?—Spencer.

[60650.]—**Geometry.**—If two exterior angles of a triangle be bisected, and from the point of intersection of the bisecting lines a straight line be drawn to the opposite angle, it will bisect that angle. How is this?—X. Y. Z.

[60651.]—**Electrical Signals in a Mine.**—Would any reader of "Ours" give me instructions how to fit up some good electric signals in a mine and to top of shaft, shaft about 200 fathoms; length underground, about one mile, with levels about every 500 yards? What would be the best wire for shaft, as we have had two different sorts of insulated wire, and they have not lasted more than a few months, and frequently repaired in that period, for the copper wire eats away in the guttapercha, sometimes going all to a green powder for a couple of inches, though cannot find the flaw until it is stripped. Suppose we want to communicate with every level, shall we want a separate wire? Are "trembling bells" or distinct bell the best for this purpose, and the difference in the price? Can get what materials I require. Also, will a "push button" for an electric wire have any influence on a barometer and thermometer if placed in the casing merely for safety?—A. O. H.

[60652.]—**Small Dynamo.**—Will Mr. Bottone or Mr. Eaves kindly assist me a little? Having made a small dynamo with success, I wish to make a larger one, about 60-candle-power. I am making it of all rough iron; fields, 5in. high, $1\frac{1}{2}$in. thick; two plates bolted to fields for poles, $2\frac{1}{2}$in. by $\frac{1}{2}$in. Could you tell me the distance to put fields apart, and what size laminated armature, and what thickness for poles? Must the poles be welded or bolted to the plates that span from field to field? Please say how many segments in armature, and size and weight of wire. I have 8lb. of 14 d.c.c. Could I use that for fields, the machine to have two upright fields? If my sizes will not be right, will you kindly give me same, and wire for same?—A Four Years' Subscriber.

[60653.]—**Rust Joints for Socket Pipes.**—Can any reader give me instructions as to making the above to stand 100lb. pressure?—W. P.

[60654.]—**Mid., S.E., and G.N. Locomotives.**—(1) Mid. Ry.—To what classes do the following engines belong: 1292, 109, 1299, 1286, 1301, 1550 (tank), 1490, 1377 (goods tank), 169 (renewed)? (2) What engines belong to the class described in *Engineering* for Oct. 20, 1876, Vol. XXII. p. 343 (heavy passenger tank)? (3) S.E. Ry.—Could anyone give dimensions of 159, 183, and 259 classes? (4) G.N. Ry.—What are the dimensions of 208, 229, 235 classes? Also, what are the engines in each class?—V. J. B.

[60655.]—**Strength of Type Metal.**—Will anyone acquainted with this subject let me know its strength by comparison with another metal?—Pica.

[60656.]—**German Ph.D.**—Will anyone please inform me what course of study it is necessary to attend at the Universities in Germany in order to qualify for obtaining the Degree of Doctor of Philosophy (Ph.D.)?—Chemical Student.

[60657.]—**Battery for Lathe Motor.**—I should like to know what would be the best battery and motor to use to work a small lathe or grindstone, and, also, if I could fit up the motor myself? I know very little about motors, and a very little about the batteries used for driving the same. Would a Leclanché or bichromate do?—J. Cameron.

[60658.]—**Indiarubber Solution.**—Will any reader kindly give me any useful hints about using indiarubber solution? I have been repairing some wading stockings for fishing, but it does not seem to last long. Ought it to be applied warm, or cold, ironed afterwards, or merely spread like butter on the material? Mine seems to be getting stiffer (in the tin) than it was at first. Does it want to be made more fluid by addition of naphtha, or would it become so by being warmed at the fire or in a jar of hot water? Any "tips" will greatly oblige—C. H. C.

[60659.]—**Getting-up Fire Brasses, &c.**—Would some practical hand kindly assist me with above? I find after dipping the work discolours before I can get it burnished and lacquered. I should also be glad to know the description of brushes used in lathe for getting up smooth surfaces, large round knobs, and scroll work; also cost of same and where procured. Also, in burnishing with oval burnisher in vice, what lubricant to prevent scratching?—Brum.

[60660.]—**Electric Light.**—To Mr. Bottone and Others.—I have a large machine stitching room that I required. Would one $2\frac{1}{2}$c.p. lamp give sufficient light for wish to light up with electric light in preference to gas. 40 lights would be each machinist if placed near the needle? Would a dynamo that will light eight 20c.p. lamps light 40 $2\frac{1}{2}$c.p. equally as well? What power would be required to drive the dynamo? I have at present an 8H.P. using about 4H.P. What would the lamps cost per doz., and what will be the cost of the dynamo? What sort of dynamo would suit us best?—W. H.

[60661.]—**Electro Motors.**—I am desirous of making an electro-motor for small launch of 2 or 3H.P. Will any of your numerous correspondents kindly give instructions how to make the same, the quantity of wire it would require, and whether two or four coils would be best to drive the same? What size wire would you advise us to use? Would cotton-covered do? I am intending to drive the motor with batteries.—Amateur.

[60662.]—**Solution of High Specific Gravity.**—Some time ago I saw in the "E. M." the account of a reader having recovered a diamond which he had lost amongst some glass, &c., and recovered it by means of a solution of high sp. gr. Will any reader kindly acquaint me with the ingredient or ingredients composing this solution, and the sp. gr. of it?—Alkali.

[60663.]—**G.E.R. Locos.** — I want the following information concerning these locos. to complete my engine list. If anyone can give it I shall be much obliged. Class, maker, date, and cylinders of 23 to 26, 125 to 162, 200 to 208, 421 to 424. Maker, date, and cylinders of 1 to 6, 7 to 22, 81 to 86, 30 to 36, 44 to 51, 105 to 116, 308 to 417, 418 to 561, 572 to 591. Date and cylinders of 40 to 43, 60 to 62, 73 to 76, 87 to 90, 137 to 139, 140 to 145, 210 to 227, 562 to 571, 610 to 639, 640 to 649, 690 to 699. Cylinders of 37 to 40, 52 to 59, 64 to 72, 77 to 80, 91 to 102, 117 to 140, 163 to 169, 170 to 199, 209 and 210, 223 to 244, 592 to 599, 686 to 689, 696. The designer of above will oblige. In reply to F. Thomas, 538 is a 4ft. 10in. 8-wheeled 6-coupled outside cylinder goods engine of the Mogul class, with outside cylinders 19in. by 26in., and pony truck at leading end. Weight, 46 tons. Designed by Adams.—G. Head.

[60664.] — **Pendulum.** — Will some correspondent favour us with a description of the best zinc and steel pendulum, say 80 beats to minute?—Daddy.

[60665.]—**Scent.**—Can a good scent be made from the lemon plant (scented verbena)? If so, how?—Daddy.

[60666.]—**Card and Wood Cutting.**—I want a method of cutting out zigzag puzzle patterns out of cardboard and wood. The fret-saw is too slow, and some of the angles are very acute. The design is on paper, and is then pasted on the cardboard or wood. Some of the designs are intricate. Is it possible to do the work by special knives, and, if so, where could I get them? A large quantity of each sort is required.—M. A.

[60667.] — **Magneto-Electric Call Bell.** — Will some kind reader, through the medium of these columns, favour me with an explanation of the mechanism of one of these bells?—Chemist.

[60668.]—**Etching Brass with an Acid.**—Would it be suitable for ornamental purposes and filled in with a dark substance? Kindly say how best to go about it, and what to use.—Rob.

[60669.]—**Gut Driving Bands.**—Which is the best way of securely affixing hooks and eyes? Should gut be prepared previously by any treatment? How can gut be kept from unravelling?—B. C.

[60670.]—**Electric Tram.**—Would Mr Bottone kindly tell me what size cores I should want for an electric tram 6 by $3\frac{1}{2}$? Also, how much wire and what size should I require? Could he please say what should be the size of armature, and of what form should it be?—A Beginner.

[60671.] — **Boiler Incrustation.** — I saw a Mr. Smither some years ago, and another correspondent of the "E. M." lately, recommending soda as a cleanser of steam

boilers. I have tried soda in the boiler I work several times, and she always leaks about the tubes. Once I applied 3lb. of soda to an 8H.P. traction boiler, newly done up, and she would not keep it in. She got dry when soda wore off. Would anyone explain the reason why?—J. G. L.

[60672.]—**Battery.**—Could someone tell me what is the most suitable and cheapest battery for lighting three 5c.p. lamps for about four hours every night? I have tried the Bunsens and bichromate, but they are too expensive and troublesome.—F. C. S.

[60673.]—**Mechanics.**—A room is 12ft. square, and the floor is loaded with 1cwt. per sq. ft. equally distributed over it. The joists, which are made of Memel fir, are 12in. from centre to centre and 10in. deep. What should be their breadth, taking the working load at $\frac{1}{8}$ of the breaking load? Note.—A bar of Memel fir, 4ft. 2in. long, 2in. square, when supported at both ends and loaded in the centre, breaks with a weight of 1,000lb.—DARENTH.

[60674.]—**Strawberries.**—I feel most grateful to those who have troubled to give me information as to strawberry growing. I have endeavoured, in my autumn treatment, to carry out the suggestions I have received, except as to removing the plants to new ground, which is impossible, as I have none for the purpose. Will Mr. S. Ray add to the obligation to him which I am under, by telling me the cheapest way of procuring the chemicals he names? I don't know where dissolved bones are to be had; but have bought bone dust from a seedsman. What quantity of green vitriol to the square yard ought to be used? I have no means of procuring what is ordinarily called liquid manure, but always use the contents of the slop pail to water the plants in the spring. The soil in my garden is very far from light, and it is very sunny, having a south aspect. I have another garden for flowers, and grow carnations. This year not more than one in five of my plants has flowered, and those but poorly. My geraniums also have been a failure, the plants growing large and very strong looking, but with few flowers. Will anyone tell me the probable reason for this?—LADY GARDENER.

[60675.]—**Fire.**—Will anyone suggest the best way of keeping in a fire throughout the night?—E. G.

[60676.]—**Mother o' Pearl.**—Can any reader give few particulars and information sufficient to enable undersigned to cut, polish, &c., mother o' pearl? Any book on the subject?—J. T. B., Calcutta.

[60677.]—**Vergara's Slides and Woodbury Tissue.**—Will some member who has used these kindly explain former and give opinion regarding both cardboard and wooden slides?—PHOTO.

[60678.]—**Varnish to Harden Paper.**—What varnish, or other preparation, can I use to make cardboard hard and strong, to use, say, for shutters of a dark slide? Has no manufacturer yet produced dark slides in papier mâché? This seems to me to be an excellent material for the purpose, and should produce light, strong, and cheap slides.—PHOTO.

[60679.]—**Ink for Window Tickets.**—How can I make a good glossy and opaque ink, various colours, bright, for writing window tickets? I have consulted last two indexes in vain.—SHOW CARD.

[60680.]—**Field Magnets.**—Will "Sigma," Mr. Eaves, Mr. Bottone, or anyone else, give me their opinions on the following? Why is it that dynamos are never made with the armature revolving in the magnetic field of greatest density? All machines, except Siemens and Gramme, have the armature near the feet of what is practically a horseshoe magnet. Sure the field is more intense when the F.M.'s and armature are in line—i.e., at the extreme end of the poles. Again, in the Elwell-Parker at the Exhibition, each of the two pole pieces on either side are wound in pairs, one loop embracing both poles. Would not the field be intensified if each pole was inclosed in its own coil? Lastly, having read everything in "E. M." for many years past on the subject of winding drum armatures, I am not at all sure that I could make one with many segments in the commutators, the diagrams in illustration of this operation being not easily understood. Of course, it is simple enough in Mr. Bottone's book, where there are only two segments in the commutator.—AMPERE-METER.

[60681.]—**Water Clock.**—In the water-clock described some time ago in the "E. M.," why have a conical drum for the wheel, and about how long will the clock go, as described?—A YOUNG MECHANIC.

[60682.]—**Leclanche Batteries.**—I have been charging some of these batteries (one with agglomerate plates and the zinc held in rubber bands a short distance from the plates, the others with porous cells containing the carbon plates and crushed carbon and peroxide of manganese and loose zinc rod), and from some cause, of which I am not aware, the zinc rods are eaten away rapidly when the battery is lowered into the fluid. I should feel very much obliged if any fellow reader could explain where the error is. I could have understood it if the cells had been connected up in a bad circuit; but the above takes place when the batteries are not in use. Is it possible to put too much salammoniac and cause the trouble? I may mention one cell is quite new, but the zinc deposits a thick, black sediment just the same as the others.—H. E.

[60683.]—**Electric Bell Indicator.**—I have an electric bell with ten pushes in various rooms, and a ten-hole indicator. It was put up by a firm not now in existence. The wires are inclosed in zinc pipes under the plaster of the walls. The bell rings well enough when any of the pushes are used; but the indicator does not act at all. How does the current get through the indicator without moving any of the discs? I have tried by moving them forward with my finger, and find that the replacing push at the bottom also refuses to act. Can any correspondent assist me by explaining the construction of the indicator, or tell me of some book on the subject?—A NEW SUBSCRIBER.

[60684.]—**Shaft.**—Will Mr. A. Gray (who answered query No. 57301, August 28th, 1885) kindly show me the method of working out the diam. of the pinion shaft from the data given?—A MILLWRIGHT APPRENTICE.

[60685.]—**Electrical.**—In what respect do the carbons of the Pollak battery differ from the ordinary carbon? Will the ordinary do as well? If not, how is the other made?—PEREGRINUS.

[60686.]—**Staining Iron Black.**—Can any reader tell us how to stain iron a good black—that will stand knocking about? The Japan blacks we use all chip off.—FIRE IRONS.

[60687.]—**Screw Cutting.**—Will one of your readers inform me how to find the wheels to cut 18 threads in $22\frac{1}{4}$in., and what wheels to use?—F. FOOT.

[60688.]—**Nickel Silver.**—Will some person please inform me if nickel silver is to be had in the form of sheets and wire, soft enough to work in every way like brass, and to be used as a substitute for it: or if there is any other metal capable of a high polish that would come cheaper than nickel?—DAVID.

[60689.]—**Silvering Glass.**—Can any one of your correspondents give the process by which mirrors are silvered—the one termed patent process?—G. H. H.

[60690.]—**Wood Carving.**—Will some practical hand kindly give the names of the tools necessary for carving common ornaments, and a few hints as to their use?—G. H. H.

[60691.]—**Wood Naphtha.**—How can I free this from water, so that it will mix with turpentine?—PETRO.

[60692.]—**Relative Positions of Flat and Eyepiece.**—Though my query is put in connection with Newtonians, it applies (mutatis mutandis) equally to Gregorians and Cassegrains. Suppose we have a mirror 10ft. focus in a 12in. diam. tube, on what principle should we fix position of flat with reference to position of eyepiece? If we put the flat 6in. within the focus of the mirror, the apex of the cone of rays would just reach the outside of the tube. If we put it 12in. within the focus, the apex of the cone will fall 6in. outside the tube; if 18in. within the focus, the apex will fall 12in. outside, and so on. For a further detail, let the field lens of the eyepiece be assumed to coincide with the outside of tube, and let it be of 3in. focus and with an eye lens of 1in. focus. Then apparently the cone of rays should be so placed that after refraction by the field lens they should form the image in the focus of the eye lens; but, if so, there must be some method of approximately fixing where the flat must be placed in order to secure this result. Now the smaller the flat the less the loss of light by obstruction, while on the other hand it must be necessary to throw the apex of the cone to a sufficient distance outside the tube in order to suit the eyepiece. What method, then, have opticians been in the habit of using to fix this said "sufficient" distance? I give a specific example because I should like whoever deals with my letter to work the whole thing out in figures, so as to render it clear. I used somehow to picture to myself this part of the world as having no winter worth mentioning, whereas now (corresponding to the end of your February) we are getting torrents of rain, hail, cold winds, and even snow—in fact, as wretched weather as even an English November can show. As far as climate is concerned, I think this of N.S.W. is simply detestable: a stew-pan in summer, an ice-house in winter, and a rapid alternation of both at other times. I hope shortly to send what may prove a useful account of the mechanical trades and kindred matters; but one caution I would at once give our English mechanics—viz., "Don't come here at present."—A. S. L.

[60693.]—**Trigonometry.**—If $\tan 2\phi = 0{\cdot}1723$, what is the value of $\tan \phi$, and how is it obtained? Can the expression $\dfrac{2 \tan A}{1 + \tan^2 A}$ be adapted to logarithmic computation?—X. Q. Z.

[60694.]—**Phosphorescence.**—There was in our orchard a rotten stump of some fruit-tree, which has now been chopped up for burning, and strange to say, it shows a strong phosphorescence in the dark, looking as if it had been rubbed well over with phosphorus, or painted with luminous paint, the light emitted therefrom being visible even in the moonlight. Would someone versed in these matters kindly state whether it is probably caused by the presence of innumerable phosphorescent animalcules, or what other cause? I should be happy to send a few chippings for inspection or microscopic examination to anyone who will forward me a stamped and addressed envelope.—A. JACOBY, Onibury, Craven Arms, Salop.

[60695.]—**Model Marine Boiler.**—Would anyone kindly assist me by explaining the way to fix in the tubes, and what size they must be, the copper No. 20 B.W.G., also give sketches of one?—MARINE.

[60696.]—**Dynamo.**—I am about to construct a small dynamo after the style of one advertised by Blakey Emmott and Co., Aug. 20th, with Gramme armature and two upright field magnets. I should like it to give a current of twenty-five volts, and twelve ampères. What I require is, what length and thickness to make field-magnet cores, what diam. of armature, and what number and quantity of wire to put on both.—BURNLEY.

[60697.]—**Electric Lighting.**—I am running six Crompton arc lamps in parallel off a compound-wound Elwell-Parker dynamo, and find that in the case of two or three lamps the current occasionally reverses, or at least burns away the lower carbons the faster. Would some electrical friend kindly explain the difficulty, and suggest a remedy?—AMATEUR.

[60698.]—**Lathe Speed Pulley.**—I have a 5in. centre back-geared headstock for treadle lathe; speeds of cone are $2\frac{3}{4}$in., $4\frac{1}{4}$in., and $5\frac{3}{4}$in. respectively. Would some kind reader inform me the diameters of speed pulleys? The belt, without alteration, should fit two of the speeds with movable piece taken out to fit small speed.—J. HUMPHRIES.

[60699.]—**Photo. Enlarging.**—How can I enlarge one figure in a group to C.D.V. size?—AMATEUR PHOTOGRAPHER.

[60700.]—**To Draughtsmen, &c.**—Is there any royal road to the division of circles or straight lines into any number of equal parts—any instrument by means of which, in the workshop or drawing office, it can be done in less time than by calculation, geometrical construction, or trial? In the best equipped shops or offices, what methods would be adopted to divide a circle of 17in. dia. into 19 equal parts, and a straight line 12in. long into 11 parts?—WORKMAN.

[60701.]—**Japanning.**—I make small brass stampings which I wish to get up to a good finish, coloured black equal to buttons. Are buttons japanned? If so, how should I proceed to japan my stampings quickly and in large quantities? Is a turning barrel the best method for taking away sharp edges, and can machinery be used for the japanning?—BUTE.

[60702.]—**Liquid Gold.**—Can any friend furnish me, through your columns, with the recipe for making liquid gold, as used in the gilding of earthenware? It burns bright in the kilns, and so saves the expense of burnishing. There is a process of bright gold gilding with a mixture of sulphide of gold and various essences. Can any one give me the proportions? I think it is called Duterte's process.—J. M. T.

[60703.]—**Galvanism.**—TO MR. BOTTONE.—I am suffering much pain from what I think is muscular rheumatism, finding no relief from hot baths, embrocations, or medicine. I should like to try the electric current. I know all about the various instruments, but nothing about the application. Will you kindly tell me if the continuous current or the Faradic is best—if the direction of the current is important. It is principally under the ribs, left side, and back to shoulders that I am now suffering.—R. J. T.

Sugar as an Anti-Incrustator in Steam Boilers.—The last number of the *Rivista di Artigliera e Genio* contains a brief, but important, article by Colonel Agostino Polto, of the Italian Engineers, giving the result of certain experiments carried out by him with common sugar as a remedy for preventing incrustation in boilers. The boiler made use of by Colonel Polto was a 20 horse-power Field tubular boiler, containing 126 tubes. This boiler was ordinarily scraped and cleaned out every forty-five days (i.e., after 380 working hours), when the average weight of scale removed, after making use of the best methods known for preventing incrustation, amounted to 12 kilogrammes. Before beginning the experiments with sugar, one-third of the tubes were purposely left uncleaned; the boiler was then filled with water and two kilogrammes of sugar added to it; a further supply of one or two kilogrammes, alternately, being added every seven days. After working the boiler for the usual forty-five days, it was found that it could be cleaned easily without the necessity for scraping it, and that the tubes which had been left uncleaned were considerably more free from scale than before, whilst the other tubes remained clean and bright; about eight kilogrammes of old incrustations were found lying at the bottom of the boiler, having become detached by the beneficial action of the saccharine solution. A similar result was obtained after repeating the experiment for a further period of forty-five days; the tubes originally left uncleaned being in still better condition, and only three kilogrammes of old incrustation being found at the bottom of the boiler. The success of these experiments proved conclusively that the boiler could be used with advantage continuously for a longer period than forty-five days, and that it could then be easily cleaned by simply injecting water. The advantages claimed by Colonel Polto for this method, if borne out by prolonged experience under varied conditions, are self-evident, and we shall be glad to hear and record the results of further trials. The sugar employed was a kind of raw sugar known in Italy by the name of Muscovade, which possesses a large amount of saccharine matter. With water of medium hardness the best results were obtained by using 10 grammes of sugar per horse-power when working the boiler ten or twelve hours a day; but the exact proportion would, of course, vary under different conditions. This saccharine solution was found to have no corrosive effect on the boiler; but Colonel Polto admits that too large a proportion of saccharine, or the use of impure water, might possibly lead to corrosive action, which, however, would probably be easily obviated by adding a small quantity of soda in the proportion of one-tenth to sugar.—*Engineering.*

A DISCOVERY which is of vast importance to New Zealand is announced. Oil has been struck near Gisborne, and the well is now producing fifty barrels a day. It is believed that there is an unlimited supply, requiring only further appliances to increase the quantity obtained very largely.

IT is claimed that by a new process white wood can be made remarkably homogeneous and tough. The result is said to be obtained by steaming the timber and submitting it to end pressure, thus compressing the cells and fibres into a compact and inextricably interwoven or interknotted mass.

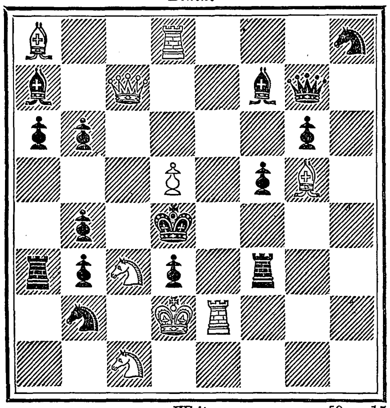
IN a recent number of the *Organ für die Fortschritte des Eisenbahnwesens* is a paper by M. Krüger, on "Conical Tires of Railway Rolling Stock," in which the author shows these to be a cause of resistance to traction and of the travelling of the rails.

CHESS.

ALL Communications for this department must be addressed to J. PIERCE, Langley House, Dorking.

PROBLEM MXIII.—BY BLACK PAWN.

Black.



White. [9 + 15

White to play and mate in two moves.

This is the last problem in Tourney C. The award will be announced in a fortnight.

SOLUTION TO 1,011.

White.	*Black.*
1. B-Q Kt 4.	1. Anything.
2. Q or R mates, or P disc. mate.	

(Six variations.)

NOTICES TO CORRESPONDENTS.

CORRECT solutions to 1,011, by A. Dean (but main variation 1. $\frac{\quad}{\text{P takes Q}}$ omitted), E. W. Edmunds, I. M. Brown, Link, J. Mackenzie, J. A. M. (a pretty problem), "——," and Isca; to 1,010, by J. Thompson, "——," G. A. A. Walker, Link; to 1,009, by Link (second solution).

G. A. A. W.—We are obliged to you for the trouble you have taken. The problems are very acceptable. We will endeavour to comply with your wish shortly.

LINK.— Your second attempt at 1,009 will not do, as if 1. $\frac{\quad}{\text{B-K B 6}}$, 2. $\frac{\text{Kt-K Kt 3}}{\text{B takes Q (ch)}}$. The same objection holds if 1. $\frac{\quad}{\text{B-Q R 5}}$, 2. $\frac{\text{Kt takes Kt}}{\text{B-Q 2 (ch)}}$.

W. DUFF.—Problems should be sent on a diagram; all variations should be given in solutions. Your attempt at 1,011 is all wrong, as 2. P takes Q, even if Black could not prevent White's second move by advancing any of his three P's.

BLACK PAWN.—Many thanks; but the idea in the last two-mover sent is too hackneyed. The problem might be made into a good three-mover.

PROBLEM-LOVERS will be glad to obtain the neat little volume of "Chess Souvenirs" by the well-known composer, Mr. Winter-Wood. Most of these problems are in two moves, and they have all been published before in various Chess Columns, including the ENGLISH MECHANIC. They are characterised by excellent finish and subtlety of conception. The volume winds up with a long and amusing tale in verse, entitled "The Unexpected Guest," written in t' e style of the "Ingoldsby Legends." In our next number we shall quote one of the compositions. Mr. W. Morgan, jun., 17, Medina-road, Holloway, is the publisher. The printing and get-up are admirable.

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve Months, Post Free to any part of the United Kingdom. For the United States, 13s., or 3 dol. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office Order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. JAMES W. QUEEN and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII. XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX., XL., XLI., XLII., and XLIII., bound in cloth, 7s. each. Post free, 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post free from the office (except index numbers, which are 3d. each, or post free, 3½d.).

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI., and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, Oct. 13, and unacknowledged elsewhere:—

REV. G. WALL.—J. T.—K. Wessberg.—A. Wheeler.—W. F. Stanley.—A. G. G.—A. Clegg.—P. London.—A Reader.—Zero.— Anxious.—M.I.C.E., Bath.—Original Querist.—Fireman. — Amateur. — Lime-Weary. — Accrington.—Veuton Veor.—Postulata.—Glatton.—W. C. —Ernest B. Martin.—J. C. D., Liverpool.—Joseph Marples.—Perplexed.—D. W. W.—Cooper's Hill.—W. Clifford.—Thomas Buckney.

WIDG. (There is a recipe for marine glue on p. 231, last volume. There are two or three formulæ, but the simplest is—Dissolve one ounce of finely-shred indiarubber in twelve ounces of coal-tar naphtha, using heat carefully. When the solution is complete, add twenty ounces of powdered shellac, and when all is thoroughly melted and mixed pour out on slabs of polished stone or metal. In some cases chloroform is used as the solvent and mastic instead of shellac; or the rubber is dissolved in refined petroleum, and twice its weight of asphaltum added. The hotter it is made the more fluid it becomes, up to 300° Fahr.)—NATURE. (They are soaked in rainwater until the soft parts are sufficiently decayed to be brushed away. The bleaching is accomplished by immersing for a few seconds in a weak solution of chloride of lime.)—C. MATHER, Altrincham. (We do not remember the subject; but if you were so told you will find references in the indices. You speak of bronzing and blueing. If it is the latter, a query appeared last week.) —W. P. (The "catch-'em-alive" fly-papers are made by coating pieces of paper with a preparation of linseed oil and a little resin boiled until sticky.)—WEE LADDIE. (The chisels are made hard by heating to a red and quenching in water, and are then brought to the required temper by heating on a hot plate until the "colour" appears, when they are finally cooled off in water. An expert smith does it at once; but it is better to repeat, as the edge can then be polished up and the right colour seen directly it appears. 2. The numbers are 1048 and 1052. The publisher will send them on receipt of ten halfpenny stamps.)—RENFREW. (It can be: whether it is so or not we do not know; but we recently mentioned that fish has been preserved in steel barrels, into which a solution consisting of water, 3 per cent. of boracic acid, a little tartaric acid, and some salt is forced. 2. Most things are poisons used in "excess." 3. No book. See indices.)—HARMONICUS. (Harmonium reeds are tuned by filing or scraping the reeds—at the free end to sharpen, at the rivet end to flatten. The scheme for getting them all to equal temperament has been given many times. See p. 322, No. 1082, for full directions for tuning a harmonium. 2. Procure the lists of the music sellers.)—ENQUIRER. (If you cannot hammer them out with the mallet, solder a wire hook to the surface, and pull them up.)—POOR OPTIC. (What do you mean by lines? A line is the 12th part of an inch. 2. Sometimes with nitrate of silver, sometimes with nitrate of copper, or tetrachloride of platinum, and occasionally with a black lacquer. See p. 401, No. 1086; and p. 168, No. 944.)—DAVID. (You want stoving japan, a preparation containing asphaltum, and you must have a japanner's oven. See an article on japanning and japans in No. 860, and the indices generally. 2. You do not say which metal you wish to deposit, but there is full information in back numbers.)—AMATEUR TURNER. (Almost all the textbooks on the steam-engine contain diagrams; but see the indices of back volumes. Nos. 995, 999, contain illustrations which will fully explain the motion and action of the slide-valve.)—H. WIDDOWS. (Dissolve shellac in wood-naphtha, about two pounds to the gallon, and add vermilion or Venetian red.)—J. BYGRAVES. (You must test with a delicate sine or tangent galvanometer and a large resistance, or on Wheatstone's plan. See the indices of back volumes or any textbook.)—F. W. G. (See p. 561, No. 1117, and many other back numbers.)—APPRENTICE. (The displacement must be calculated according to the rules, and the weight of the body is then equal to the weight of the liquid displaced. You should procure such books as Molesworth's Pocket-book (Spon) and Templeton's "Workshop Companion," published by Crosby Lockwood and Co.)—A VICTIM. (Your question is incomprehensible. Having served the time agreed upon in the indentures, you are free to do as you please.)—OLD MECHANIC. (The only way is to article him for, say, three years, which will cost from £100 to £300, according to the status of the professional and the amount of the work he has to do. As to education, the lad will require as much as he can get, and should attend art classes and those on building construction.)—GLASS. (The only way is to regrind and repolish; but if the scratches are deep that will involve too much labour.)—A. Z. (The best course is to consult a surgeon.)—YOUNG. (Very! Yes, if it is only water; but as soon as it becomes warm the air is driven out and any lime it contained is deposited, so that it becomes just a trifle less in quantity. Is that the "straw" you want?)—COLONIAL. (We could not afford space for such a discussion. A specific question might perhaps be answered, but as a rule it is very difficult to advise about emigration.)—DOT. (To prevent collapse in case of the water becoming short. The plug is inserted in the furnace crown, and should melt when uncovered with water, thus allowing steam to escape.)—PORTHOS. (No one could value the instrument without seeing it, and the other question is so purely of personal interest that we cannot find space for such a query. Surely in your town there is one dealer who could answer your questions. We think the name is more likely to be Forster.)—Z. Y. X. (Yes, certainly; intensification is necessary at times. Why not procure one of the cheap manuals which give instruction in the art?)—LITTLE JIM. (It is generally linseed oil well rubbed in, but sometimes it is varnish or French polish. Directions will be found in many back volumes. 2. By measuring the distance between the points when furthest apart; that is, just within the distance that the spark ceases to pass. See even recent back numbers.)—E. B. WALKER. (The other Nos. are 616, 627, 636, but only 627 is in stock.) YOUNG ENGINEER. (See Reed's "Engineer's Handbook," published by T. Reed and Co., Sunderland. You must have served an apprenticeship to an engineer of three years at least, and have also served one year at sea in the engine-room. Then you must be able to give a description of boilers and their construction with all their accessories, and understand how to correct defects. Ditto of steam engines. Must write a legible hand, have a good knowledge of arithmetic, including mensuration, and so on. You must deposit a fee of £1 as a preliminary.)—PADDY. (Instructions have been given many times. See indices.)—INQUIRER. (No, there are none made for the purpose. Fine Turkey sponge should be used, as described in No. 1054, p. 295.)—AMATEUR ASTRONOMER. (You must get the focus with some degree of accuracy, because that is the length of main tube required. Of such a lens it is more likely to be 40in. than 30in.)—R. S. S. (Balkwill's "Mechanical Dentistry," or Cole's "Manual of Dental Mechanics" may give the information required, for we know of no work that answers exactly to your requirements. They are both published by J. and A. Churchill, New Burlington-street. Hunter's "Mechanical Dentistry," published by Crosby Lockwood and Co., Stationers' Hall-court, E.C., describes the various kinds of artificial dentures. Its price is 7s. 6d.)—C. B. (By placing in fine sand heated to about 140° Fahr., and rubbing well with a piece of rather coarse flannel or dogfish skin. See No. 999, p. 240.)—YANKEE. (See a recent discussion and consult works on the subject. 2. About the thorough bass look on p. 465, No. 1113; and offer the stones to a manufacturing jeweller, or advertise them in the Sale Column.)—A. JACOBY. (Nothing remarkable in such matter being phosphorescent, but what is the actual cause can only be stated after examination.)—GEO. FISKE. (See Nos. 946, p. 226; 1083, p. 348; and 1085, p. 390. Look through the indices of back volumes for a number of articles on lantern slides, and procure the required colours from any dealer in artists' materials.)—YOUNG AMATEUR. (Answered over and over again. The best way is to take indicator diagrams; but an approximate estimate can be formed by taking the area of the piston in inches, multiply that by 2, by the length of the stroke in ft., by the number of revolutions per minute, and by the pressure in pounds. Divide the total by 33,000, and the quotient is the horse-power.)—SAMUEL TAYLOR. (We do not know. Some observers believe they have seen the so-called planet Vulcan, which is supposed to be roaming about between the sun and Mercury; but although its existence is possible, some say probable, there is at present practically no evidence which can be deemed satisfactory.)—CONSTANT READER. (See p. 477, No. 1036, and the indices generally; but procure also the Calendar of the London University.)—A. R. B. (Answered many times. See p. 353, No. 1056, or any textbook of optics. The length of the main tube may be taken as approximately correct.)—F. B. (Why not ask the maker himself? Those we have seen had a revolving shutter, and, as we said when first brought out, are well worth the price.)—J. E. (How can any one say without personal examination? Seek the best medical advice within your reach.)—HENDON. (Registration of a design protects for five years only; a patent for fourteen years. Registration of a design is not the same as patenting an invention.)

CHARGES FOR ADVERTISING.

MICROSCOPICAL ADVANCES.—XIII.

Minute Coloured Imagery.

By DR. ROYSTON-PIGOTT, M.A. Cantab., F.R.S., F.R.A.S., Memb. Roy. Coll. Physicians, Fell. Cambridge Phil. Society; formerly Fellow of St. Peter's College, Cambridge.

First Order of Interstitial Colouring.

THE intensity of the lustre displayed by many objects, such as diatoms and moth scales, is worth particular attention. Whether we can arrive at satisfactory conclusions on this rather mysterious subject or not, the attempt to solve the question is full of interest and thoroughly worth making.

These are two remarkable points: whilst in scales the most brilliant blue colouring is entirely extinguished by viewing them by transmitted light; the colour is instantly resuscitated by using reflected light.

Of the moths, *Morpho Cypris* and *Morpho Menelaus*, the latter is gorgeously exhibited at South Kensington. On the other hand splendid colours are omitted both by reflected and transmitted light in the case of selected diatoms.

To begin: with an intensely blue diatom, examined by a low power against the light, in the centre there is a reddish glow fading gradually into an intense Oxford blue*. Investigate the structure with the best glasses extant; the whole is resolved into minute beading very symmetrically arranged, crowded in all blue parts; more sparse as the red centre is reached. These beads or spherules are chiefly of two orders, radiate or arched. You see long radii of well separated beads, then arcs of a concentric form, packed by threes or fours between the radii. The whole are displayed upon a circular disc.† The beads all display intensely black *Test Rings* with brilliant focal discs suspended aërially above each. The illumination preferred was, for this resolution, attained by an exquisite two-thirds objective used as a condenser, a plane mirror, and an ordinary moderator lamp. In one sense, we had certainly radiating lines closely packed, and we know Sir David Brewster discovered closely-packed lines in mother-of-pearl, and ascribed its pretty colours to this lined structure. The strange fact, however, crops up that as the interstitial spaces widen the colour changes from blue to crimson; yet the beading remains the same size, both radiate and central. Are we to ascribe the deep blue colour to the gauge of these spaces? It seems as though the red rays could not find admittance through these minute vacuities, but the blue can.

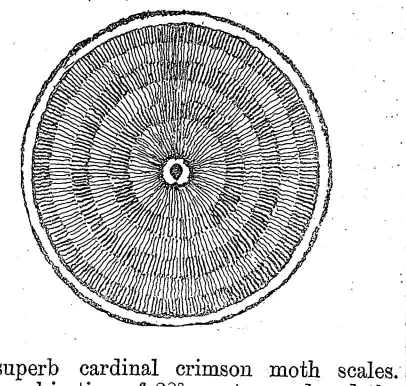
Another observation. An objective of 70° aperture destroys the blue colour, turning it into a pale French grey. As you focus upwards a blue dim disc reappears.

An exceedingly fine 1-10th imparts a slightly ruddy glow when the brilliant focal discs sparkling above the *Test Rings* assume their greatest brightness. With a glass of 1·43‡ aperture, of surpassing excellence, a pale sapphire tint can be easily seen without the black test rings, especially in the central part of the Eupodiscus, where the red colouring appears with a low power. This effect can hardly account for the intensely deep azure blue already described. In a focal plane about 1-6,000th above the focal discs, red eidolic dots like red currants are seen, but this cannot account for the rich cerulean blue in hand. I am obliged to fall back on the hypothesis that the interstitial spaces admit here only the blue rays, but admit red when they are large enough.

In rather a large Eupodiscus the diameter of the brilliant disc within the test ring of a spherule was 1-45,000th of an inch, and of the red eidolic dot suspended above the 1-55,000th nearly.

Several tints are developed in different specimens apparently, according to the closeness of the spherular arrangement:—pale sea-green, deep violet, crimson, lemon-yellow, brown, deep umber, salmon colour. In Mr. Watson's guinea slide there are many more colours, and an exquisitely-arranged circle

FIG. 1

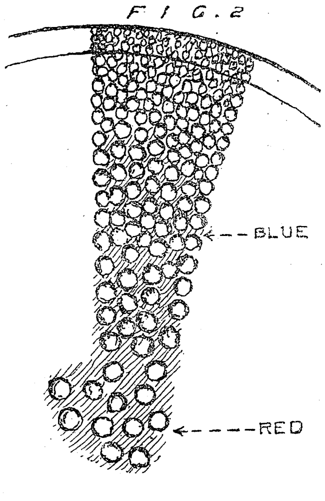


of superb cardinal crimson moth scales. A ½in. objective of 22° aperture reduced the deepest blues to a much paler colour—steel blue. Power 200.

On one of these discs a piece had been chipped out, exposing a second set of beading belonging to the under surface, and placed about 1-6,000th of an inch deeper. Having so often seen the lower beading in diatoms, I cannot but regard this observation as valuable evidence on the point.

My swinging substage of 1862 carrying a 1½in. fine objective tilted at an angle of 20° exhibits on a black field a group of astonishing brilliance under sunlight illu-

FIG. 2



mination (⅔rd objective and D eyepiece). An entirely new order of superb colouring supervenes. Black lined reticulations, radial bars glowing with all prismatic hues, demonstrate the variety of rays decomposed by the refracting molecules, and emanating in every possible direction.

Eupodiscus Argus.

Fig. 1.—Represents the radial bars. These glitter with golden and every other prismatic hue × 200.

Fig. 2.—The same frustule exhibiting sparse beading giving red, and closer beading emitting blue rays × 2,500.

By oblique illumination, many diatoms display a beautiful iridescence with transmitted light; the colours change also by rotating the object, as well as by altering the angular apertures. Parallel rays answer the best; obliquity then develops intensely black shadows—often crescentic in refracting spherules and semi-lunar blackness startles the eye of the observer under the highest powers. The scene constantly changes with the obliquity. The swinging substage (made in 1862) was of the greatest service.

Second Order: Transmitted Colours.

Interstitial transmission of light through the minute crevices in these diatoms is not the only cause of the colours. With the best powers, we have to deal with infinitely small and infinitely numerous sprays of light decomposed into prismatic colouring by the refractive nature of the silicoid structure of minute spherules capable of forming various focal points, spurious discs, eidolic forms, and mixed phenomena. Nor is this all. The immersion oils import their own peculiarities. The residuary errors of the objective also enter into the game. Objects in higher or lower focal planes, with the very best glasses, assume different tints. The position of the internal lenses again manipulates colour.

My best glass, Powell's 1-12 (1·43), at its best estate, displays two colours at *different focal planes*—salmon pink and pale sapphire blue. Immersion oils of great variety change these colours. Powell had informed me for many years that an immersion fluid of low dispersion and high refraction was a desideratum. I tried a great many in 1870. Sir David Brewster worked out these qualities in an exhaustive manner, and from his tables most valuable data may be obtained.

Indeed, for every fresh immersion oil the best objective requires new adjustments. Observe the following table.

The first column is the index of refraction for mean rays (μ). The second dispersion or distance between the red and blue rays of the spectrum ($\triangle\mu$).

	μ Index of Refraction.	$\triangle\mu$ Dispersion.
Oil of Rhodium	1·503	·022
„ Lavender	1·457	·021
„ Rape seed	1·475	·019
„ Olive	1·47	·018
„ Rosemary	1·47	·020
„ Sweet Fennel Seed	1·506	·028
„ Almonds	1·47	
„ Brick	1·47	·021
„ CASSIA	1·64	·089
„ Mace	1·481	
„ Nutmeg	1·497	·021
„ Peppermint	1·47	·019
„ Dill Seed	1·477	·023
„ Pimento	1·51	·026

Castor oil has some excellent properties; also 1 grain of chloride of gold dissolved in glycerine has answered extremely well in my hands. The white, pallid oil of olives (in which I intend to dissolve proportions of camphor) strongly recommends itself in the table*. Camphor has a refraction 1·50.

The scintillations of diatomic beads, when all is done that can be for attaining perfection of definition, well reward the attentive observer. As a mass of highly refracting spherules, or *quasi*-lenses, their play of colours is most remarkable. Rich bundles of iridescent rays emanate from all these wonderful little gems;—small though they be, they are huge compared with the wavelets of light that play around and within them. Old-fashioned glasses reveal none of these beauties. The corrections were too coarse. The colouring of many objects is more exquisite

* Eupodiscus fulvus is a good example.

† In Watson's German slides (£1 1s. each), many tints are selected, and the diatoms form patterns resembling engine-turning.

‡ 1·43. This exceeds the numerical aperture of any of Carl Zeiss's objectives, which only reach 1·40.

* Burgoyne et Cie, 16, Coleman-st.

and fascinating as the perfection of the instrument advances.

My friend Mr. Fletcher, with a fine 1-15th by Ross, sees 10 colours on the arched surface of the Formosum, using a fine ½in. objective as condenser.

These effects are totally different from the first order of colouring caused by the interstitial penetration of blue or red wavelets already discussed. It is a new order of beauty dependent upon many complex combinations.

To illustrate these points it is necessary, first of all, to allude to the earliest experiment with a small lens placed in a beam of solar light.

Sir John Herschel's experiment with this small solar beam presents phenomena of the highest order of interest, though these were only viewed with a small lens. But imagination fails to conceive beforehand the splendid beauties of the solar marvels exhibited by examining a miniature sun with a power of 1,000 diameters, instead of about 10. (Sir John, unfortunately, does not give the focus of the hand lens he employed.)

The experiment was this: A solar beam admitted through a small aperture in a shutter was received on a distant lens which converged to a solar focus,* thus forming a miniature of the hole in the shutter by a totally uncorrected lens.

This was now viewed with a small lens: coloured rings were displayed of great beauty, though of minute diameter. The following is Sir John's list of colours, the rings following nearly in the order of the colours of thin plates. It should be stated that as the distances are varied, these rings expand or contract in vivid contrasts of prismatic colouring:—

1st Order.—White, pale yellow, yellow, orange dull red.

2nd Order.—Violet, blue, *broad and pure*, whitish greenish yellow, fine yellow, orange red, very full and brilliant.

3rd Order.—Purple, indigo blue, greenish blue, pure brilliant green, yellow green, red.

4th Order.—Good green, but rather sombre and bluish; bluish white, faint red.

5th Order.—Dull green, faint bluish white, faint red.

Sir John also says:—When the eye lens and hole are brought nearer together, the central white spot contracts into a point and vanishes, and the rings gradually close in upon it in succession, so that the centre assumes in succession the most surprisingly vivid and intense hues; he used an examining lens of short focus. At page 484 of his article on "Light," he gives a much longer table of these coloured rings at measured distances of the hole from the eye lens, which it is unnecessary to detail.

When the writer employed the leisure of some years of research on "Circular Solar Spectra," by means of a magnifying power of 1,000 with exquisite definition, he was not aware of this early experiment.

It seems never, however, to have occurred to Sir John that the image-forming lens itself was afflicted with both spherical and chromatic aberration. If we substitute for this lens a very perfectly corrected lens, such as a modern objective, these rings nearly all disappear, and we are left with a most brilliant central white spot surrounded with an intensely black and very true circular ring, the slightest deviation from truth in this *Test Ring* denoting either eccentricity of the component lenses, bad setting, or inaccurate curvatures; of course, also errors of achromatism are at once vividly developed.

It should be especially noted that in the Herschelian experiment the angular aperture of the condensing lens is exceedingly small, as also that of the observing lens. In the experiments to be described, enormous apertures were generally used, as in immersion glasses.

The inconvenience, too, of an ever-changing solar beam of light strongly militates against continuous observations and written records.

For this reason I have endeavoured to devise totally different kinds of apparatus. A heliostat is an expensive instrument when driven by clockwork. In the new arrangements the solar beam remains stationary for many hours. Instead of Herschel's minute shutter aperture, a fine one-fifth object-glass of 140° aperture is placed 200in. from a horizontal microscope. The axis of this objective is directed to the horizon, and to the azimuth of the sun, rays from which can enter at all angles up to half apertures.

Any small adjustable simple plano-convex lens is placed beneath the stage, and its spectrum is now viewed with a powerful microscope (× 1,000 diameters).

So soon as the spectrum is caught in the field of the microscope, all your manipulative skill will be required to subdue, on a bright day, the magnificent—the almost blinding—splendour of the scene. You are viewing a focal image of the sun formed by a simple lens. The excessive effulgence of the accompanying phenomena often elicits a shout of delight from the beholder.

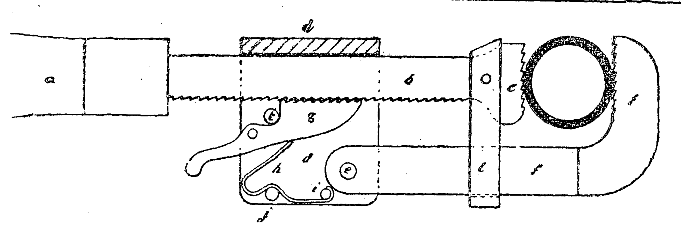
It is necessary that one optical axis only should pass through the instrumentation; slight deviations or obliquities develop the most exquisite figures, composed either of ellipses, parabolas, or hyperbolas.

In the midst appears Herschel's brilliant white spot, surrounded, first, by an intensely black ring, strangely distinct amid such wonderful brightness. The colours, vivid beyond experience, form concentric rings expanding and contracting with every change of focus. When the stage lens is more achromatic and true, the rings gradually diminish in number, so that a very perfect stage objective reduces the immense circular spectra to two, or even one, black central ring as a margin to the brilliant white sun spot, or spurious solar image. It is necessary to choose sunshine on a clear day, free from haze. May is generally the best month.

(To be continued.)

* Diameter of solar beam passing through the hole of the shutter was 1-30th of an inch; its distance from the luminous point about 78in., and its distance from the eye lens 24in.

A NEW WRENCH.



ANOTHER improved wrench has been recently patented in this country, this time by Messrs. Potter and Gulick, of Orange, Essex Co., New Jersey, and its principal features are shown in the annexed illustration, which is a sectional side view. The invention consists of a wrench of simple construction which is easily manipulated. *a* represents the handle of the wrench; *b* is the shank of the fixed jaw *c*, which is provided with teeth along one edge to constitute a rack. This rack *b* is embraced by a U-shaped frame *d*, free to slide thereon. Between the two parallel pieces of frame *d* there is pivoted at *e* the shank of the movable jaw *f*. *g* is a dog likewise pivoted between the cheeks of frame *d*, and having a serrated biting edge to engage rack *b*. A suitable spring *h* within frame *d* bears with its free end against the dog *g* and tends to hold it against rack *b*. The patentees prefer to make the spring *h* of the form shown in the drawing, that is to say, it is partly bent around two pins *i*, *j*, located at opposite sides of the spring. Below the biting edge of dog *g* there is a strong pin *k* fitting into a concavity of the dog. This pin is of importance, inasmuch as it bears against the dog when the wrench is used, and takes a large portion of the strain from the pivot of the dog. *l* is a yoke pivoted to shank *b* and embracing the shank of the movable jaw to properly guide the same. The operation of the wrench is as follows: To open the same, a handle on dog *g* is pressed towards the rack *b*, and thus the dog is released from the rack. The frame *d* and movable jaw *f* may now be slid up the desired extent. After the work is inserted, the dog is released, and caused to engage rack *b* by spring *h*. The movable jaw is now pulled down until the work is tightly clamped between the jaws.

MINERS' SAFETY-LAMPS.

THE question of safety-lamps for use in mines has recently come to the fore, and it is to be hoped that something more definite than the report of the Royal Commission may soon be arrived at; though that report was definite enough in one particular—viz., that none of the lamps tested were safe in all conditions of the atmosphere of a mine. There is some reason to think that an electric lamp can be made perfectly safe, and at the same time cheap enough for general use, but sufficient experience has not at present been obtained in practical work to justify a confident expectation that a difficult and vital problem has been finally solved. Probably before long Mr. Lever's prize will be won, however, for there are two, if not three, electric safety-lamps which appear to answer the conditions, and at least two improved forms of the oil lamp which can compete with a fair chance of success. According to Mr. Arnold Lupton, lecturing recently at the Yorkshire College, all the safety-lamps at present in use are modifications of the Davy, and, in his opinion, the Mueseler, the use of which is enforced in Belgium, and the Stephenson lamp, if well constructed, are the best lamps for use. Where fire-damp is known to exist, the greatest essential is protection from the current of foul air and gas. The only means of protection is to put the lamp behind a cover, and if the Davy lamp is put in a tin case, from being a most unsafe lamp it becomes one of the safest. The Royal Commissioners considered it might be safely used in a current of 2,000ft. velocity per minute. In a safety-lamp there should be nothing between the glass and the oil pot, so as to secure the best possible light. It is still more important, however, for colliers and deputies, before a lamp is used, to see that all parts are in their proper places, a departure from this rule involving far greater risks than the use of less safe lamps. After describing the Swan, Morgan, and other inventions, Mr. Lupton said that the lamp of the future would be one of the following: An electric, with secondary battery like Swan's, or with a primary battery like Walker's, a bonneted three-gauze lamp, a bonneted Mueseler lamp, a Morgan three-gauze lamp, or a Clifford lamp, if it stood the tests as well as its inventor said it would. Some experiments made by Mr. Lupton on the 8th inst., in which the Clifford lamps were extinguished without firing the gas, suggest the question whether, after all, it would not be better to use oil-lamps which are extinguished in the presence of fire-damp, in preference to those which are supposed to be incapable of exploding a mixture of gas and air. It goes without saying that the miner would rather have a lamp that continued alight while showing the presence of an explosive mixture; but unless a lamp can be made which is proof against all conditions of the air of the mine, it would no doubt be safer to employ lamps which are extinguished before they can fire the gaseous mixture.

Many experts indeed consider that the chief use of a safety-lamp is as an indicator for detecting the presence of gas, and that working should not go on in the presence of an explosive mixture; but unless the lamps are so arranged that the explosive mixture will put out the flame, it is certain the miners would go on working long after the appearance of the flame of the lamp indicated the nature of the surrounding atmosphere. It is stated that the new Morgan lamp is absolutely proof against the most severe tests, while at the same time it gives a high illuminating power, and is not readily extinguished, as some are, by the ordinary movements necessitated by the work of the miner. Some of the safety-lamps are too easily extinguished by a trifling accident, and miners naturally object to tramping back to the lighting station—it may be a mile from the place of working—in order to have the lamp relit. The Morgan lamp, which was awarded the Gold Medal at the Inventions Exhibition, has a double shield made of two plates of sheet metal perforated in such a manner that the holes in one shield are never opposite those in the other. Any blast of air directed against the outer shield has its force greatly reduced before it gets through the inner shield, and then it is met by the gauze cone and chimney protecting the flames. The lamp is, besides, perfect in minor details, and well deserved the gold medal; but if the newest pattern is better still, it would seem that at last we have a real safety-lamp. Still, it must be acknowledged that experimental tests carried out with a blast of explosive gases do not produce exactly the same conditions as may occur in a mine, where the lamp may be altogether surrounded and consequently filled by an explosive atmosphere. What is wanted is a lamp that is safe in all conditions of its environment, and probably it is only in connection with electrical devices that such will be found.

THE GREAT BRUSH DYNAMO AND THE COWLES PROCESS.

THE great "10-ton" 42in. dynamo manufactured for working the Cowles Electrical Furnace by the Brush Company has been tested, and is evidently a remarkable machine, if we may judge from the reports which have been published. The metallurgical world—for that matter the scientific world—is now awaiting with interest the result of the practical operations in extracting aluminium by means of the electric current, although there is no doubt of the practicability of the method. That has been demonstrated: the question to be settled is the price at which aluminium alloys can be sold, for if as low as promised we shall undoubtedly see a revolution, and it is possible that steel may find itself supplanted by one of the new alloys. The great Brush dynamo weighs altogether 21,671½lb., or, according to some, 21,900lb., and is thus near enough to be called "10-ton" in British measure. Calculated to give a current of 3,200 ampères, with an E.M.F. of 80 volts, and a normal maximum current in the fields of 80 ampères, at a speed not greater than 600 revolutions, it has accomplished that standard at 405 revolutions, yielding 249,000 watts, the E.M.F. being 83 volts. The largest current measured was 3,400 ampères, with an E.M.F. of 68 volts, and if a more powerful engine had been driving, there is no doubt 300,000 watts might have been reached in safety. A few dimensions, with weights of this, perhaps, memorable machine, may be of interest. The armature, 42in. in diameter, contains 1,600lb. of iron, and carries 825lb. of copper wire, the total weight being 4,300lb. It consists of 16 bobbins, each carrying 21 turns of best copper wire, two strands lying side by side, the wire being 0·35in. in diameter. These 16 bobbins are operated in multiple arc, thus giving 32 strands of copper wire of the diameter above stated, and about 65ft. long. Sixteen copper bars carry the current from the bobbins to the commutator, each bar being 1in. by ½in. in section. The two commutators are coupled in multiple arc. The driving shaft carrying the armature is 13ft. long by 5½in. in diameter at the main bearing, and is made of open-hearth steel. A 40in. pulley on this shaft is driven by a double leather belt 44in. wide. The field magnets, eight in number, consist of cylindrical cast-iron cores 11in. in diameter by 16in. in length, and wound with 30 layers of 102 turns each of copper wire, 0·134in. in diameter,—all the eight wires being coupled in multiple arc, as in a shunt-field. Thus combined they have a resistance of about one ohm, total, cold. The pole pieces are of peculiar form, and are fitted carefully to the field. They weigh 67½lb., while the pole-piece stands weigh 18lb. The eight magnets with their copper-wire weigh 9,295lb. That the whole machine is well proportioned, mechanically and electrically, was demonstrated on the trial, when, after a run of two hours, the armature was cool enough to handle in all parts, as were the other portions of the dynamo, the bearings being free from heating and cutting. The maximum horse-power of the engine which produced the above results with this dynamo is 355; but it is now connected, we believe, to a Victor turbine of 550 horse-power, and we may shortly expect to hear of the work effected in producing aluminium and its alloys.

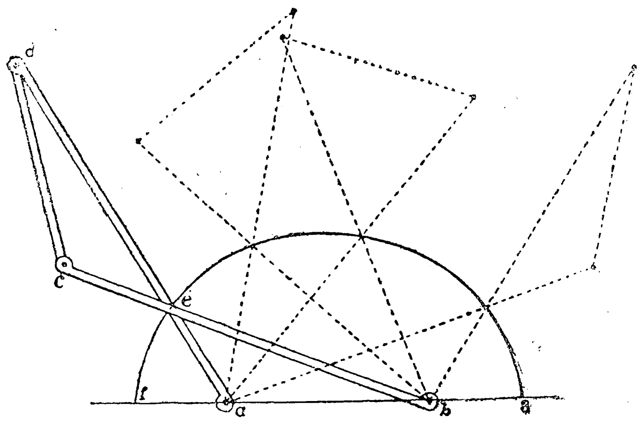
Meanwhile, we learn from a paper by Prof. C. F. Mabery, who is associated with the Messrs. Cowles, that the results of working with a 30 horse-power engine are sufficient to encourage the belief that the energy represented by 300 horse-power and more will enable the company to produce aluminium at a very low price. In contradiction of the assertion made by Dr. Werner Siemens that aluminium could not be reduced without copper, Prof. Mabery says that mixtures of metallic aluminium and carbon have been frequently taken from the electrical furnace in large quantities. A product which has attracted considerable attention during the past year is obtained by reducing alumina in presence of iron. A cast iron is formed containing sometimes as much as 10 per cent. of aluminium, and this product is used to facilitate the working of crude iron and to introduce into the various grades a small percentage of aluminium. The slags resulting from this reduction are composed chiefly of calcic aluminate and cast iron. In the reduction of aluminium in the presence of copper, a yellow product is frequently taken from the furnace, which is composed of metallic aluminium to the extent of one-half or three-fourths, the balance being silicon and copper. With a small percentage of calcium it is also formed in the absence of copper and then contains a higher percentage of aluminium and often contains nitrogen. It has a resinous lustre and decomposes water at 100° C. The aluminous slags are composed of reduced metal, calcic aluminate, and fused oxide, and since they have always proved to contain about 1 per cent. of carbon, which is liberated in the gaseous form of hydrochloric acid even in the absence of iron, a carbide of aluminium may also be present. A remarkable effect was observed in a bar of 10 per cent. bronze which had been heated for the purpose of forging. It was allowed to become too hot, and when struck the entire bar assumed a crystalline condition. Some of the individual crystals were nearly perfect in form, resembling certain forms of the isometric system. A striking analogy between them and certain forms of meteorites has recently been observed by Mr. O. W. Huntington, of Howard College. In reduction of silicon, the formation of a greenish-yellow substance is frequently observed, and it has been proved by analysis to be a new oxide of silicon—SiO. By fusion with fluxes it is converted into the dioxide, and hydrofluoric acid acts upon it the same as upon the dioxide.

At the meeting of the American Association for the Advancement of Science an ingot of aluminium was shown containing less silicon and iron than the average commercial metal, although no special care had been taken to obtain a pure product. Experiments are now being carried on which it is expected will ultimately result in the discovery of a method of working which will materially reduce the cost of a metal which is so valuable because it is so remarkably useful, and also so abundant in the state of oxide.

A NEW ELLIPSOGRAPH.*

THERE are so many ellipsographs and methods for drafting the ellipse, that a new one can hardly be said to be called for; but the study of the curve is interesting to many from a purely theoretical point of view, and the following device may be new to the subject. It is new to me, both as to its mechanism and its principle.

Four links, *ab*, and its equal, *cd*, *bc*, and its equal, *ad*, are joined together as in the figure, the points *a* and *b* being fixed. As the system is moved about the fixed centres, the intersection of the two crossed links will follow the outline of an ellipse, *fg*, which has the two centres for its foci, and the link *ad* for its major axis.



The figure shows the instrument in rough outline, to illustrate its principle only; but it is easy to see that it would be adjustable for different ellipses if the centres were mounted on slider s, or otherwise made movable on the bars. It would also be a simple matter to attach a double slider that would slide on both the crossed bars and hold a pencil point at their intersection.

HOW TO PREVENT THE FADING OF SILVER PRINTS.†

I CLAIM for my process that it will prevent fading under ordinarily favourable circumstances, and where the prints have been *kept from damp*. I may say that I have never seen any fading in my work when it was fairly treated in the manner I am about to place before you; and I wish to impress upon any who may desire to make trial of it that they should be very particular to follow my method, otherwise I must not be held in any degree responsible for what failures they may meet with.

In the first place, I may state that I prepare my paper and do my printing in the usual way. I have tried many kinds of toning baths in my time, but always fell back upon chloride of lime. My bath is made in this way:—

Chloride of lime	6 grains
Common whiting	20 "
Chloride of gold	15 "
Water	6 pints

Allow the solution to stand aside for a few days before use. It will tone for a long time, and, when it begins to show signs of exhaustion, is reinvigorated by the addition of a little gold at each time of toning. Nearly any description of tone may be had from it, ranging from warm brown to black.

I think it essential always to fix with newly-

* By GEORGE B. GRANT, in the *Journal* of the Franklin Institute.

† By ROBERT IRVINE. A paper read before the Edinburgh Photographic Society.

dissolved hypo. The practice of leaving some of the solution previously made use of I consider a mistake; and though at the moment better results may be thought obtainable, still there is no question but it induces fading. After fixing, I put the prints under a tap furnished with a rose full of very small holes, which, while it helps to keep them in motion, does not break or crush them in any way. The vessel I use for the purpose is a wooden tub, the sides and bottoms of which are pierced with a great many holes, which are fully ¼in. in diameter—care being taken, of course, to see that the inflow is equal to the outflow, so as to keep the prints floating. After washing fully an hour, I take them out and lay them on a thick glass plate, and, with a smooth wooden roller, press all the water out of them, at the same time, I believe, removing nearly all the hypo remaining. I then return them once more to the washing water, and put a good quantity of common salt along with them, which I think effectually helps to neutralise any traces of hypo that may be left. I let them now wash an hour or two, after which it is, and has been, my practice, for a year or two past, to take them out and put them into a fresh water, in which a small quantity of alum is dissolved. After remaining and being moved in this for a short time, I gather them singly, and wipe each print with a soft sponge and water, and then press them in a mass as dry as possible, when they are ready for mounting. The mountant I prefer is gelatine. Starches and pastes easily sour, and, in time, cause prints to fade.

I do not pretend to be even a second-grade photographer, but I can distinctly say that during the twenty-three years I have been in business I never saw my prints fade if I adhered to the method I have just detailed. It has occasionally happened that when I was pushed for time I have omitted to follow precisely the above form; but in usual circumstances it is my invariable practice. I may say that I have prints in my show-cases and elsewhere that have been exposed to sun and frost for a long time, and they will stand examination as to fading, and come well out of it. I have hundreds of prints in boxes that have lain by me for many years unfaded; and I shall be glad if these remarks prove of service to the profession in any degree, because it is one of the great reproaches of our beautiful art that, so far as silver printing is concerned, the effects, no matter how charming they may be to-day, cannot be depended upon to endure for any considerable length of time, and too often but for a very short time indeed, compared with other productions of art and skill.

THE INFLUENCE OF MUSIC ON THE CEREBRO-SPINAL SYSTEM.

It has long been a familiar fact that susceptible, or perhaps we ought to say very impressionable, nervous centres, either of brain or cord, or both may be influenced by music. Whether the influence exerted is not purely physical—perhaps mechanical and of the nature of vibratory movement, of a nature akin to that exemplified by the phenomena of sensitive and musical flames, and obeying the laws of concord and discord which Newton demonstrated as determining the chromatic and diatonic scales respectively, which Groves further illustrated in the induction of his doctrine of the correlation of forces, and which Tyndall has reduced to practice—may be a moot question, but we cannot doubt that it will sooner or later be settled in the affirmative. However that may be, the fact remains that music does act powerfully on the majority of nervous systems, and there is reason to think that the brain is not alone affected. For example, the movements of the lower limbs both in dancing and in marching are distinctly influenced by music, independently of the consciousness. When the brain at first participates in the excitement produced, it may become engrossed with other matters, and rhythmical muscular movements of the extremities, and in a lesser degree of the trunk, will be continued automatically in harmony with the music. Direct impressions on the cerebral centres are probably transmitted through the auditory centre. Thus monotonous and slow music will exert a calming influence, provided that it be not too slow to be in harmony with the nerve habit of the individual, as in that case it may irritate. It is also essential to the success of any endeavour to bring the brain under the control of music that it should first arrest the attention either by its power or sweetness, and then gradually conduct the organism into harmony with itself. A measured cadence of the sort likely to calm the mind is more likely to augment than to allay irritation, unless it begin with a powerful appeal to the brain in a key which accords with that in which the cerebrum is at the moment itself working. This has not, perhaps, been sufficiently well understood in some attempts which have been made, experimentally, to use music as a remedial measure. So with endeavours to rouse the spirits by music, the opening needs to be plaintive and in the key of melancholy which harmonises with the brain state of the patient. The attention being arrested and the cerebrum reached through the auditory centre, the key must be gradually changed, and the time quickened in such manner as to change the brain state. No great progress will be made with the employment of sound, and form, and colour as remedial agents, powerful as these agents really are, until we dismiss the unscientific idea of "mind," and begin to regard the brain as an organ which, like all other parts of the body, obeys physical laws and performs its function by purely physical processes.—*Lancet.*

THE FIRST IRON BOAT.*

The county of Lancaster is already famous as the birthplace of the first practical steamboat, which was placed on the Bridgewater Canal by Fulton, and I think it would not be too much to say that the great majority of the modern machine tools in the workshops of the world have been invented in this shire. It may give us some satisfaction to know that the first iron boat was also made in this county, certainly just inside our borders, at Cartmel, near Lancaster, by John Wilkinson, about the year 1750. John Wilkinson was in partnership with his brother and father, their chief business being in the manufacture of flat-irons for smoothing linen. It is related that John's father bought his iron in the molten state, by the ladleful; it was then carried across the high road to the small foundry, and there run into these smoothing-irons. The Wilkinsons prospered, business increased, for John invented the box iron with its inside heating piece. They erected more extensive works in the neighbourhood, engaged themselves in smelting the rich hematite ores, or what was then called Furness iron. The furnaces were at Nelson House, near Lindal, in the parish of Cartmel. They used the peat and turf of the district for fuel, and to get a proper supply of this to the furnace John Wilkinson designed a short canal which was cut through the turbary, and the iron boat was constructed, which created great astonishment along the whole country side.

This first small iron boat at Cartmel was succeeded by others made by Wilkinson. The pioneers of inland navigation were at work, pamphlets were written, folios were printed to show how the wealth of the country might be increased by a proper system of inland navigation. The Duke of Bridgwater, Brindley, Telford, and other enterprising men had created these waterways, the Manchester and Worsley Canal was being imitated, the Birmingham Canal had been finished, and the Great Staffordshire Canal ran not far off Wilkinson's furnaces.

Wilkinson had heavy contracts, and the boat builders were very busy supplying these new canals with boats; but the arts of peace and the arts of war created a great demand for John Wilkinson's manufacture. He obtained the contract for the Paris Waterworks, which included all the pipes, tubes, cylinders, and ironwork for that enormous undertaking, which was considered the greatest of its kind of that day. His friend, James Watt, having designed the steam engine, and Wilkinson not being able to get boats of wood to convey the materials for the above contract, determined to design boats of iron to go down the Severn and the canals. He was also busy smuggling cast-iron guns 4ft. long into France. These were consigned under the name of water-piping—sometimes merely as metal water-pipes—to be re-cast into guns when they got to France. They were taken from Willey by means of a cast-iron tramway to the banks of the Severn.

The next iron barge that was made was called the *Trial*, and, according to the record of the day, Wilkinson set to work building this at Willey, with John Jones as chief smith—John o' Lincoln he was called.

The *Trial* was finished in 1787, and a great crowd came down to witness the launch of the iron barge, of which Wilkinson wrote in a letter dated Broseley, July 17th, 1787:—"Yesterday week my iron boat was launched; it answers all my expectations, and has convinced the unbelievers, who were 999 in 1,000. It will be a nine days' wonder, and then be like Columbus's egg." Wilkinson went on building other barges. In a letter dated Bradley Iron Works, 20th October, 1787, he says:—"There have been two iron vessels launched in my service since 1st September; one is a canal boat for this navigation, the other a barge of 40 tons for the river Severn. The last was floated on Monday, and is, I expect, now at Stourport with a lading of bar-iron. My clerk at Broseley advises me that she swims remarkably light, and exceeds even my own expectations."

* Extracted from the address of Alderman W. H. Bailey, President of the Manchester Association of Engineers.

POWER ABSORBED IN CUTTING CAST-IRON.

For the purpose of determining amount of power used in cutting iron by different shapes of lathe tools, a dynamometer was attached to a 20in. Fitchburg lathe, the use of which was tendered by T. R. Almond, Brooklyn, N.Y., for a course of experiments. Fig. 1, shows method of attaching dynamometer to lathe. A is the main shaft, H the lathe counter and step pulley. L is the lathe, and I the step pulley on spindle. Pulleys C and G remain as ordinarily used for driving the lathe ahead. The reverse belt was removed from pulleys F and B. A short counter shaft J was mounted back of the lathe, and the dynamometer D placed upon it in line with pulley F. Tight and loose pulleys E received a belt from pulley B, which was moved along the line shaft from A, to where it is now shown. This method of attaching relieves the dynamometer of much wear; the clutch K enabled direct power from pulley G to be

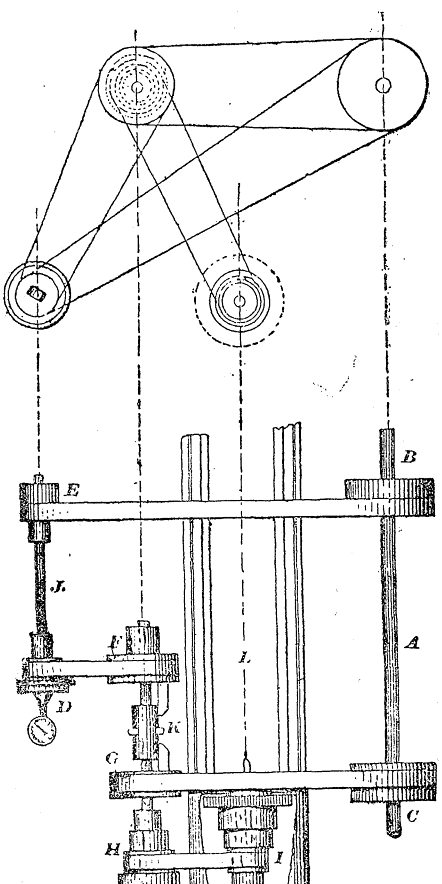


Fig. 1

used in getting a cut ready; when by engaging K with pulley F, the dynamometer reading may be taken at will. The dynamometer used was patented by Horace C. Hovey, Ayer, Mass., and was loaned for this course of test by its present owner, R. H. Gray, of the above named town. The dynamometer shaft is secured to the hub by eight set screws, placed in pairs at angles of 90° in order that the dynamometer may be centred and secured upon the shaft. The shell, or belt pulley, is separated from the hub by a number of rolls, which convert movement between hub and shell from sliding into rolling friction. A bar cast to the hub engages the shell pulley through the medium of springs which are compressed according to the power applied through the pulley E, and applied to the lathe by pulley F. By means of a device similar to steam gauge rack pinion, hand and dial, the movement between the dynamometer hub and shell is registered. In making up the readings upon the dial face, the shaft J was locked to prevent all movement, and a 5lb. weight attached to pulley D by means of a wire and hook which engaged one of the set screw holes.

The figure five on the dial indicates where the pointer stood with a load of 5lb. on the wire. Weights of 10lb, 15lb., and up to 60lb., were placed on the wire, and the position of the hand marked on the dial as before. The dial reading now represents actual pull of the belt in pounds. To

* By James F. Hobart in the *American Machinist.*

reduce it to horse-power, multiply circumference in feet of pulley D, by dial reading, by revolution per minute, and divide by 33,000. It is found upon stopping the apparatus that the dynamometer would return to within ¼lb. of zero, this amount representing resistance of internal friction, and friction of clutch pulley F. When this dynamometer was first tried, the index hand was found to fluctuate excessively at every increase or decrease of resistance. A slight touch upon pulley D would cause the hand to jump up 30lb. to 50lb. upon the dial plate. To remedy this defect, the shell and hub were also connected by an equalising device consisting of a piston 1¼in. in diameter, working in a cylinder full of oil. Two holes about $\frac{1}{16}$in. each in diameter were drilled through the piston, which fitted easily into the cylinder. Before many experiments had been made, it was found necessary to close one of the holes entirely, and to put a piece of wire in the remaining hole which reduced the area to about one-third its original size.

The dynamometer in these tests was run at a speed of 365 to 390 revolutions per minute, thus giving it a capacity of about one horse-power.

In boring a 14in. flange coupling, various conditions of hardness or density were found. The coupling casting was 7in. long, and cored out about 3½in. diameter.

Two rough cuts were run through the casting, leaving the hole 3·75in. in diameter.

A boring bar 1½in. square, *a*, Fig. 2, was bolted to the lathe carriage in place of the usual tool-post, and a cutter *b*, 1½in. diameter, put through a hole,

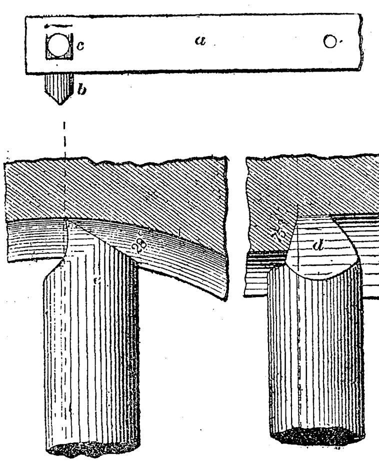

Fig.2

and secured with a set-screw *c*, near end of boring bar. The cutting edge of tool *d*, was ground at an angle of 75° with axis of hole to be bored. The clearance shown at *e* was 28°, and rake of tool 39°. The dynamometer reading at beginning of cut was 15·5lb., of which 8·25lb. was consumed in lathe and countershaft friction, leaving the direct bell pull consumed by cutting tool equal to 7·25lb. The speed of dynamometer was 365 revolutions per minute; circumference of its pulley, 1·7 + feet, giving a belt speed of 620·5ft. per minute.

At point of cutting tool, the diameter of bore being 4·02in., the circumference was 1·05 + feet, and the work making 15 revolutions per minute, taking off a chip ·135in. by ·021 + thick.

From the above data may be calculated the direct pull upon cutting tool to drag it through the iron, or to force the iron over the tool. At the dynamometer 4498·625 foot-pounds are consumed in driving work over the cutting tool, exclusive of 5119·125lb. required to drive lathe and countershaft. At the end of cutting tool the work done is as above, 4498·625 foot-pounds, and as the work travels at a velocity of 15·75ft. per minute, then a pressure of 285·63 + pounds is necessary to force the work over the tool 1ft. per minute.

As the boring proceeded, considerable difference in density of the iron was noticed. For convenience the readings of pressure will be given in pounds pull upon tool at circumference of the work; in all cases the friction of lathe and shafting being deducted and only the resistance of cut being given.

When the cut was first started the dynamometer indicated 7·25lb.; at a depth of 3in., 8·50lb., and at points diametrically opposite the pressure varied about one pound, but this variation gradually disappeared as the tool approached the face of the coupling, which was upward when the casting was made.

The following table shows the number of pounds required at different depths of the bore or towards top of casting, at which place more power was required, although the iron is supposed to be the more dense at the bottom.

BORING TOOL.

No.	Depth of Bore.	Pull on Tool.
1	0⅓in.	285·63
2	3	334·87 +
3	4	305·32 +
4	4½	245·96 +
5	5	256·07
6	5½	275·77 +
7	5¾	305·32 +
8	6	285·63
9	6¼	324·32 +
10	6½	337·87 +
11	6¾	364·41 +
12	7	384·11 +

The variation of one pound at points diametrically opposite, as above mentioned, will make a difference of cutting pressure of about 38·69lb. pull on the tool, and is caused by the variable density of the iron. This condition of the casting will readily explain why holes in gear and pulleys are sometimes found to be oval, and why we cannot always turn up a true cylindrical shape in the lathe. In forcing crank pins into their places after the work has been accurately bored and turned it is sometimes found that the pin is not true with the wheel or crank. How much of a factor may be represented by the above difference in density of iron is yet not entirely known, but must be considerable. With the couplings mounted on 4$\frac{7}{16}$in. iron arbor between centres turned up to 60°, the friction of lathe and countershaft, when dynamometer ran 365 revolutions per minute, and lathe 1 to 43·75 of dynamometer was 8·25lb.

SCIENTIFIC SOCIETIES.

LIVERPOOL ASTRONOMICAL SOCIETY.

THE first meeting of the sixth session was held on Monday, October 11. The president, the Rev. T. E. Espin, B.A., F.R.A.S., occupied the chair. Eighty-one members were elected and ten candidates were proposed. Of the total number, 15 were from Liverpool, 24 from other parts of England, 9 from Ireland, and 43 from North and South America. The Rev. T. E. Espin and Professors Asaph Hall and S. Newcomb were elected Associates of the Society. The secretary announced the deaths of four of the members during the past year. A short account of their lives had, he said, been prepared, and would be published in the *Journal*. The president complimented the Council on their able management. He thought the long list of members which the secretary had just read was without a parallel in any scientific society in the world, and likely to prove by far the most important paper of the evening. To the students of the educational branch he would especially address himself, and he thought he could promise they would never regret their choice of a science. Of all others, astronomy was the most fascinating, and the love of it only increased with its study. As an example of devotion he instanced Sir W. Herschel, who once spent more than forty hours of uninterrupted work in putting the finishing touches on his large speculum, and could not be induced to leave it even for food. It had been said that night work was injurious, but he had never found it so, though last winter he spent many nights knee-deep in the snow. Perhaps this immunity was in some measure due to the clearness of the air, since no astronomer would think of uncovering his telescope in foggy or rainy weather. He had headed this address "Stellar Variation: a Chapter in a World's History," and they would be prepared to hear that he regarded variation as a stage of development through which, perhaps, every star either has passed or must pass. Might not variation be due to stages of axial rotation? Let them suppose in the star's early history, a central heat and external vapours in a cooler state; they had then a spectrum of the third type. Let the axial rotation go on increasing, and the temperature also, then there would be a struggle between the hotter and cooler vapours, and we should have an irregular variable like 19 Piscium. Passing to a time when the rotation had quickened, they could imagine the absorption vapours more and more compressed in area; this would give a long-period variable with great variation in its light. Taking R Hydræ as an example, they would find its period in 1785, 500 days, but in 1825 it was only 461, and in 1870 it had decreased to 437; in other words, its rotation was now 60 days less. Let them suppose that a time would come when, by increased rotation and temperature, the vapour would no longer have power of cohesion, and would be thrown out irregularly all round the star. At this stage they might expect to find a spectrum merging from III *a* or into II, and the light irregularly variable. He forbore to speculate on the origin or the end of such a star, or whether it ever had been or would become a nebula, but these chapters in a star's history were full of interest. In variable stars they might read something of our sun's history. In the geological record had they any hints as to a past history of great variation? Those strata, each showing a higher period of development, were they impressions of contemporaneous solar development? Would our sun ever lose these vapours of absorption and stand out as a star of the first type like Sirius, with its present heat increased a hundredfold? How bright will it then be, and what will be the period of its rotation? Will animal and vegetable life exist under those conditions? Such questions must remain unanswered in our time, and we must be content to observe, to watch, and to record.

In a paper "On the Retardation of Encke's Comet," Mr. W. H. S. Monck, M.A., F.R.A.S., accounted for its slower motion by its passing through systems of meteors, rather than by the generally-accepted theory of a resisting gaseous medium. Wherever meteors existed the motion of any celestial body must be retarded by their influence, because a large majority must be coming from an opposite direction. This would be understood if they considered that in walking along a tram-line they would meet with more cars than would catch up to them; not only so, but the momentum would be greater as their own motion would, practically be added to it. The number of meteors flying about space was greater than most people imagined. It had been computed that the earth receives the impact of several millions in the course of a single day. In the case of a solid body like the earth the shock would be too small to be appreciable; but with a light body like Encke's comet, the effect would be to seriously retard the motion. Collisions with meteors would also be more frequent nearer the sun—at all events, up to the distance that Encke's comet approached it. Astronomers had inferred the presence of a great mass of meteors inside the orbit of Mercury as the only way of explaining certain irregularities in the motion of that planet, and, as both meteors and comets would then be near their perihelion, they would be moving with increased speed, so that the retarding effect would be greater. Mr. W. F. Denning, F.R.A.S., pointed out that in July and August, when the earth is further from the sun, there are quite double the numbers of meteors that are visible in January and February. This alone would go far to negative Mr. Monck's theory that meteors were more crowded near the sun. It should also be remembered that Encke's comet was not a cohert mass of matter, but a collection of very small bodies. The effects of its collision with meteor streams would therefore be of a very different nature to that in which a solid planetary body like the earth was concerned. A meteor stream would probably pass completely through Encke's comet—itself but a highly-condensed group of meteors—without affecting its motion. There would be virtual, but not actual, collision, except, perhaps, in the case of a very few individual atoms of the opposing systems. A solid body presenting a compact front would receive all the force of the impetus, but in the case of a comet and meteor stream there would only be permeation.

The secretary read a paper on the "Search for Vulcan," by Mr. T. W. Backhouse, F.R.A.S. It was of great importance that the existence of an intra-Mercurial planet should be determined, and a systematic watch ought to be kept during the period when, according to Leverrier's calculation, it was possible for Vulcan to be in transit. This would entail very little extra trouble now that the Society had so many observers in both hemispheres, many of whom were constantly watching the sun in the interests of other branches of the science.

Mr. T. G. Elger, F.R.A.S., addressed some remarks especially to beginners. In many respects, he said, a study of the moon presented advantages such as no other celestial body could claim. There we saw the actual surface of another world unobscured by clouds or exhalations, and could contemplate the marvellous details of its structure rather in the spirit of a physical geographer rather than of a telescopist. The beginner would soon see that the moon had been nothing like so exhaustively studied as to leave nothing for small telescopes to do. In commencing this study they should first make themselves acquainted with the more obvious characteristics into which its surface is divided, and in this they would be much assisted by Webb's, Mellor's, or other convenient maps. As a rule, they would find the majority of objects easier to observe when the sun had just risen on them. At those times the surface was brought into strong relief by shadows, the significance of which they would soon learn to interpret.

Mr. K. J. Tarrant counselled beginners not to be discouraged if they could not at once distinguish objects with small apertures. Nowadays, if a man wrote to say that he had picked up such-and-such an object, or had split a close double star, somebody else would be sure to do so with a smaller aperture; indeed, he sometimes wondered whether imagination had not a great deal to do with it. This kind of thing was very disheartening, and no

doubt many a good telescope had been condemned on very insufficient grounds. Of course, a great deal depended upon the air. As an example, there was one abnormally clear night last winter when the fifth and sixth stars of θ Orionis were quite easy objects; whereas on the next night, which was apparently quite as clear, they were not distinguishable.

Papers were also read on the "Classification of Variable Stars," by Mr. J. E. Gore, and on "Cassini," by M. C. M. Gaudibert. Other papers were received on "The Effects of Terrestrial Heat on the Moon," by Mr. W. H. S. Monck; on "Some Remarkable Sunspots," by Miss E. Brown; on "The Masses and Distances of Binary Stars," by Mr. J. E. Gore; on the "Lunar Crater Mädler," by Mr. T. G. Elger; and on "Interesting Facts about Binary Pairs," by Mr. K. J. Tarrant. Arrangements were made to hold educational classes fortnightly, and Mr. J. S. Brown, 274, Upper Parliament-street, was appointed secretary to the branch. A large number of donations of books, &c., were handed round for examination, and a vote of thanks was passed to the donors. The secretary stated that one of the new features of the *Journal* would be a review of the books presented to the Society, so that distant members would be acquainted with these additions to the library.

SCIENTIFIC NEWS.

From Dun Echt Circular No. 128 we learn that Mr. Ritchie, jun., of Boston, Mass., has circulated the following elements and ephemeris of the comet discovered by Mr. Barnard on Oct. 4, and by Dr. Hartwig on the next day: T = Dec. 11·40, G.M.T.; $\pi - \Omega$ 89° 26′; Ω 135° 39′; i 106° 15′—mean equinox, 1886; log. q 9·7763. The ephemeris for Greenwich midnight reads, Oct. 24, R.A. 11h. 23·5m., N. Dec. 4° 28′, brightness increasing up to Dec. 3, when, according to an extended ephemeris computed by Dr. Becker, the greatest N. Dec. (15° 18′) will be reached.

The comet discovered by Mr. Finlay will, according to Dr. Holetschek, of Vienna, arrive at perihelion on the 22nd of November. It is approaching the earth as well as the sun, and is becoming slowly brighter, travelling now in an easterly direction through Sagittarius.

Amongst the Gresham Lectures of the session we note that next week the Rev. E. Ledger will deliver four on the "Astronomy of the Last Twelve Months," on Tuesday, October 26, and three following days. On Tuesday the subject will be the meteors of Nov. 27, 1885, and recent achievements in celestial photography, the latter continued on Wednesday and Thursday, while on Friday the subjects will be recent observations of Jupiter and the great red spot, observations of Saturn, and Prof. Langley's investigations on Heat Radiations of long wave-length considered with reference to the sun, the earth, and the moon. We have indicated only the chief items to be taken up. The lectures are delivered at Gresham College, Basinghall-street, E.C., commencing at 6 p.m., will be illustrated by the limelight, and are free to the public.

It has been understood in connection with the Liverpool Astronomical Society that when a foreign country could count as many as fifty members, those members should be at liberty to form themselves into a branch society of the L.A.S. Pernambuco has, it appears, just sent in its fifty-first member, and it is not unlikely that it will claim the privilege, and Mr. G. W. Nicolls will probably be the secretary of the first branch with probably a hundred members before long.

The death is announced of M. Dubosc, the renowned Paris optician who assisted M. Leon Foucault in the construction of apparatus, and especially in the electric arc lamp which bears his name.

It is understood that a number of members of the British Association will visit Australia (Sydney probably) in 1888, and it is now proposed to hold a meeting of the various scientific societies of Australasia in that year, and to form an Australasian Association for the Advancement of Science on the model of the British Association.

Temperatures recorded by non-professional observers—too often merely copied or accepted on hearsay evidence—are not to be trusted. Not long ago a work was issued in which the extremes of temperature in different parts of the empire were given, and were freely quoted in the newspaper press without a suspicion of their absurdity. Dr. John Rae has politely attributed one of these extraordinary records to the "instruments" rather than to the observer, for in the *Times* it has been recently stated that the temperature ranges in the North-West prairie land of Canada from 58° below zero to 106° above zero in summer—a range of only 164°! It is well-known to observers of experience that thermometers, even when carefully made and tested, require skilled attention, for portions of the spirit become vaporised and detached during the hot weather. Dr. Rae expresses the opinion that the thermometer which indicated 58° below zero in Manitoba was from 13 to 15° in error. An instrument for measuring accurately very low temperatures is wanted as much as a reliable pyrometer for testing the temperatures of molten metals.

The effect of long-continued heat artificially applied to certain vitreous rocks, like obsidian and pitchstone, has been investigated by Mr. F. Rutley, of the Normal School of Science, whose paper on the subject has lately been published by the Royal Society. Thin sections of the rocks in their normal condition and after exposure to heat in a glass furnace have been studied microscopically, and the resulting changes of structure exhibited in a series of illustrations. It is not likely that in nature rocks are ever subjected to absolutely dry fusion; and hence another series of experiments is to be made, with the introduction of water, so as to imitate as closely as possible the actual conditions of nature.

The exhibition of Colonial and Indian woods at the Exhibition has introduced many who can appreciate their value to more remarkable specimens of timber than can be obtained in this country. Mr. Dougall says that from experience gained years ago he is convinced that in the stinkwood (Oreodaphne bullata) of the Cape we have an article of "national importance," if it is used only for the stocks of rifles and guns. It is so remarkably fibry and tough that it cannot be snapped. The sneezewood (Pteroxylon utile), too, is useful for piles, posts, cabinet, and waggon work, as its peculiar smell prevents the attacks of the teredo, and other wood-eaters. Umzumbit, another Cape wood, is admirably adapted for bearings, having, it is stated, a life seven times as long as lignum vitæ

The use of sugar, or a saccharine liquor, for mixing lime and cements has been known in some parts of the world from "time immemorial," and many of those whose business it is to make plaster moulds, or casts, mix the plaster of Paris with a solution of sugar in water. Surgeon-General W. R. Cornish calls attention to the fact that the practice of mixing jaggery, or unrefined sugar, with mortar is very ancient, and masonry properly cemented with such mortar is not easily removed without blasting.

Another petroleum engine—that made under Eteve and Hume's patent—has been recently exhibited, and favourable accounts have been published in the daily papers. The trials were made at the Holderness Foundry, Hull, where four engines were shown at work, two using benzoline, and two common petroleum. We illustrated the improved form of the Brayton hydrocarbon engine so long ago as March 9, 1877, but little has been done with petroleum engines in America since.

The Company of Carpenters intend opening a Workman's Institute and Lecture Hall in Jupp-road, Letts-road, Stratford. In connection therewith it is proposed to establish classes with workshops for carpentry, joinery, plumbing, and other trades connected with building; also cooking classes for young women.

At the meeting of the San Francisco Microscopical Society, held on Sept. 22nd, Dr. Stallard delivered a brief address on "Endarteritis," or morbid development and subsequent degeneration of the interior coat of arteries. The structure of the three layers of tissue of which arteries are composed was described in detail. The interior coat, it was explained, was most liable to become morbidly affected. When the blood is forced through an artery at an abnormal velocity the interior layer manifests a disposition to resist the increased pressure by thickening, and should the pressure be of long continuance it frequently results in the formation of a tissue lining the interior of the artery which, constantly increasing in thickness, obstructs the flow of blood through the vessel more and more, until in many cases the artery is completely closed. This morbid growth is frequently traversed by pseudo blood-vessels, but ultimately becomes completely disorganised, usually by petty degeneration. During the complete or partial obliteration of an artery, nature usually attempts to remedy the evil by a greater flow of blood through the adjacent smaller blood-vessels, and under the unusual pressure these frequently burst. Dr. Stallard exhibited a large number of preparations showing arteries in their normal condition, as well as during the gradual progress of the disease. The preparations were stained with various re-agents, and were much admired for their beauty and interest. The secretary, Mr. A. H. Breckenfeld, exhibited a slide of the beautiful diatom *Arachnoidiscus Ehrenbergii*, the frustules of which had been electro-plated with gold by Dr. A. Y. Moore, of Cleveland. The slide was not only strikingly beautiful, as seen under the binocular microscope with a ½in. objective; but the plating process was evidently of value in rendering the markings more distinct. In this particular case, the true elevation of the radial costæ was much more obvious than in the natural diatom.

USEFUL AND SCIENTIFIC NOTES.

Exhibition at Toulouse.—A permanent exhibition of patented inventions, improvements, and new productions will be opened at Toulouse on the 1st of November, under the patronage of the local Chamber of Commerce. The aim of the promoters is "to centralise on one spot inventions, improvements, and new or useful productions which are scattered in various depots almost without interest and without success; by a constantly attractive exhibition, with free admittance, to bring together those interested from the whole district to visit this industrial, commercial, and agricultural museum; and to concentrate the efforts for publicity and representation of the exhibitors, to obtain, by the power of union, a maximum of results with a minimum of expense."

Large Docks.—The docks of the world 500ft. in length and over are as follows:—Birkenhead No. 1, 750ft. long, with a width of 85ft., and a depth of 25ft. To save repetition it may be said that the figures which follow for the other docks are in the same rotation as those above. Birkenhead No. 2,750ft., 50ft., 25ft.; Portsmouth No. 10, 644ft., 88ft., 27ft.; Portsmouth No. 7, 644ft., 80ft., 25ft.; Carleton, N.B., 630ft., ——, 28ft.; Sydney, N.S.W., 630ft., 84ft., 30ft. 6in.; Gawel, Greenock, 515ft., 70ft. 24ft.; Liverpool, "Canada," 501ft., 100ft., 26ft.; Auckland, N.Z., 500ft., 110ft., 33ft. on the sill; Table Bay, South Africa, 500ft., 68ft., 26ft.; Cadiz, 500ft., 62ft., 26ft.; Quebec, 500ft., ——, 24ft.

Glass, porcelain, and other metals can be soldered by an alloy made as follows: Copper dust, obtained by precipitation from a solution of the sulphate by means of zinc, is put in a cast iron or porcelain-lined mortar and mixed with strong sulphuric acid, specific gravity 1·85. From 20 to 30 or 36 parts of the dust are taken, according to the hardness desired. To the cake formed of acid and copper there is added, under constant stirring, 70 parts of mercury. When well mixed, the amalgam is carefully rinsed with warm water to remove all the acid, and then set aside to cool. In ten or twelve hours it is hard enough to scratch tin. When required for use, it is to be heated so hot that, when worked over and brazed in a mortar, it becomes as soft as wax. In this ductile form it can be spread on any surface, to which it adheres with great tenacity when it gets cold and hard. This alloy is intended to be used to solder such articles as will not bear high temperature.—*American Druggist.*

Chamois skin may be cleaned by rubbing into it plenty of soft soap and then laying it for two hours in a weak solution of soda and warm water. At the end of this time rub it until it is quite clean, rinsing it in clean warm water, in which soda and yellow soap have been dissolved. It should then be wrung dry in a rough towel, pulled and brushed. This process makes the leather soft and pliable. It should never be rinsed in clear water. The soapy water causes it to become soft.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents. The editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, *332, Strand, W.C.*

All Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

⁂ *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks, a vice from whence great inconveniences derive their original."—*Montaigne's Essays.*

VEGA AND ITS SURROUNDINGS—PLANISPHERE—α ARIETIS—VISIBILITY OF THE MOON BY EARTH-SHINE—ALLEGED MEASURABLE INTERNAL MOVEMENT OF THE EARTH'S AXIS OF ROTATION—MEASURES OF DOUBLE STARS: STRUCTURE OF THE SIDEREAL HEAVENS, &c.—ABSENCE OF BASIS OF ARGUMENT.

[26389.]—SINCE writing letter 26279 (p. 84) I have returned home, and availed myself of the earliest opportunity of examining the field about Vega, as requested by Mr. Sadler; I regret to say with a practically negative result. Of course, the comites A and B of his map on p. 10 were steadily seen. Sometimes either δ or γ would flash up for a few seconds, but I could not hold it long enough to estimate its magnitude even roughly. I fancied that I caught another of his stars, too (the largest in the southern part of the field); but it may have been merely fancy. The detection of such very minute points is rather beyond my instrumental capacity.

If "Al Farad" (query 60622, p. 141) will reflect a little, he will see that it is impossible to delineate the stars covering the concavity of the heavens on a plane surface save by some mode of "projection." Suppose that this is the equidistant polar one. Then if the Pole were in the zenith (as it would be at the North or South pole of the earth) the plane of the horizon on the map would coincide with the plane of the Equator, and would be a circle. But this would not hold good anywhere else, because the plane of the visible horizon, although, of course, itself a circle, must obviously be inclined to the plane of projection at an angle = the co-latitude, and be projected on that plane as an ellipse whose eccentricity would depend on the latitude. "Al Farad" may get some idea of this if he will first stand a cylinder upright upon a plane surface, when, of course, its base will be circular. If now, though, he inclines his cylinder at, say, an angle of 51° to the original surface, and cuts the bottom of it parallel to such plane, so that it may remain permanently at that altitude, he will find on inspection that the bottom of the cylinder is now no longer circular but elliptical. With reference to his question concerning α Arietis, "Al Farad" will find that Smyth, in the "Bedford Catalogue," gives its position angle as 107°, the difference of R.A. of the components 19·5 seconds of time! and their magnitudes as 3 and 11. Turning now to Loomis's "Practical Astronomy," we find α Arietis among his tests of illuminating power. Of course for this purpose position angles are not given; but the American astronomer, while adhering to Smyth's magnitudes, gives the distance of the components as only 30″. I am quite unable to give any explanation of this discrepancy.

In reply to "Vortex Atom" (query 60625, p. 141) he has been told quite correctly that the visibility of that part of the moon unilluminated by the sun is referable by earth-shine. Five minutes' study of the diagram of the moon's phases which have appeared in every book on astronomy yet published will show that when the moon is "new" to the earth, the earth is "full" to the moon, and as the surface which we present to our satellite is more than thirteen times the size of that which she exhibits to us, at such time she receives light enough from us to render her otherwise dark limb visible. But, of course, as the moon waxes to the earth the earth wanes to the moon, and ultimately sends her too little light to be returned in a visible form. The phenomenon of "The old moon in the new moon's arms," as the country people call it, is visible for a few days both before and after new moon: in fact, the earth-illuminated part of her disc is rather brighter before new moon than after it. The illusion that the sunlit crescent of the moon is larger in diameter than that perceived by earth-shine is an optical one, having its origin in what is known as "irradiation," in virtue of which every bright object appears to encroach upon its darker surrounding. "Vortex Atom" may make a very instructive experiment on this for himself, if he will get a sheet of black and a sheet of white paper, and superposing them, cut out two discs of identical (say 1in.) diameter. If now he will paste his black disc on his white paper, and his white disc on his black paper, the latter will seem so notably the larger of the two that but for the fact that he has cut them out with his own hands he will find it difficult to persuade himself that they are of the same size.

In letter 25273 (Vol. XLII. p. 446) I expressed grave doubt as to the truth of an assertion by M. Folie, the Belgian Astronomer Royal, that the poles of the earth shift measurably upon its surface. In reply to this, "some person or persons unknown" attacked me in the number of *Ciel et Terre* for February 15th, and invited my attention to the (alleged) fact that Maxwell, Peters, and several others had not only calculated but measured the small displacements of the pole. Well, in M. Flammarion's review *L'Astronomie* for the current month, there appears an article on this subject by a very much greater astronomer and mathematician than I am, or even (I write it with fear and trembling) than M. Folie himself—I mean Professor Asaph Hall, of the United States Naval Observatory at Washington, the world-renowned discoverer of the satellites of Mars. In this very valuable essay (which, as it is in French, I trust M. Folie will read for himself) after a short explanation of M. Fergola's projected series of observations to be made at intervals of 50 years, at several pairs of observatories differing but slightly in latitude in various parts of the globe, for the purpose of ascertaining whether there is really any secular change in latitude or not, Mr. Hall goes on to discuss the question whether terrestrial latitudes are subject to alteration in the course of the year; and, after treating the subject exhaustively, comes to the conclusion that they are *not.* Or, at all events, if there is any such alteration, it is of so extremely minute a character, as quite to elude our existing means of observation. This is really in effect the conclusion at which La Place arrived, and which he thus expresses in his "Système du Monde": "Mais toutes les recherches qui j'ai faites sur le déplacement des pôles de rotation à la surface de la terre m'ont prouvé q'uil est insensible." So if I erred—as to which a difference of opinion exists between M. Folie and myself—I have had the satisfaction of doing so in very good company indeed.

Having returned to my books, I will now endeavour to redeem the promise I made to Mr. Atkinson in letter 26279 (p. 84) to reply to his query (60369) on p. 46. Imprimis, with reference to δ Cygni: Mr. Muschamp Perry's own letter, on p. 330 of the *Observatory* for October, will probably have removed all my querist's difficulty with reference to the seemingly great discordance in the measures of this star. Next, the latest measures of 70 Ophiuchi that I can lay my hands on are those of Seabroke, made in 1883·69, when he found the position angle was 43·7°, and the distance of the components 2·77″. But see the *Observatory* for May, p. 199. With reference to δ Herculis, it was measured by Flammarion in 1877, when its position angle was 181·6°, and distance 18·43″. In the same year (1877·66) Jedrzejewics found the quantities to be 182·9″ and 18·1″ respectively. Seabroke measured ξ Scorpii several times in 1883. His last measures (1883·64) gave A B position angle 194·5° distance 1·14″, and A C 71·8° position angle, and 11·8″ distance. Of Σ 2525 Cygni, the three latest measures I can find are those of Schiaparelli in 1876—position angle, 232·2°; distance, 0·43″: of Dembowski in 1877·82—position angle, 238° (?) distance, 0·25″(?); and lastly, of Engelmann in 1883·26—position angle 47·9°, distance 0·234″; whence it is not difficult to understand why your correspondent fails to see it otherwise than single. Sir William Herschel says that the distance of 46 Draconis is about 1½! Finally, the only omission in Secchi's remarks (which are to be found in columns 238 and 239 of Vol. XLI. of the *Astronomische Nachrichten* for 1885) occur where the . . . . appears in the quotation on p. 385 of "Celestial Objects for Common Telescopes." The words suppressed are merely ("car elles supportent très bien l'illumination"). All that Secchi says about Cygnus is this: —"Je signalerai aux astronomes ce que s'observe surtout à 17h. 57m. d'A.R. et 18° 50″ de Decl. Aust., comme une place qui contient une foule de ces particiliarités; même dans le Cygne il y a plusieurs examples." Not a word does he utter, though, about their situation in Cygnus.

I have, on rare occasions, seen some pretty wild stuff in these columns; but I am not sure that, as a specimen of hopeless rubbish anything has ever appeared to surpass letter 26387, on p. 156. Why in the world does not "F. T.," before presuming to attempt to instruct others, get up, at all events, the very rudiments of the subjects of which he proposes to treat. Any shilling book on Mechanics would have saved him from his astronomical utterances; while, concerning his geology, it may suffice to remark that he writes, as, though the various "formations" found in these islands extended round the globe like the coats of an onion!

A Fellow of the Royal Astronomical Society.

SUNSET PHENOMENON.

[26390.]—On the evening of 30th September last, about 6.5 p.m., the sky being very clear and quite free from clouds, I noticed four pinkish streamers radiating upwards from the sun's place; they did not commence exactly at the horizon, but at a height of a few degrees above it, and terminated at an altitude of 10° or 15°. The phenomenon lasted about three minutes and then totally vanished.

I may say that in various parts of South Africa, where a succession of cloudless days and nights prevail for a considerable time, I have seen the same thing, only in a vastly more intensified and glorious phase. There roseate-purple streamers projected on a deep blue sky would extend across the heavens and meet in the eastern sky at a point presumably 180° from the sun's place, and approximately as much above the horizon as he was below it. The rays were so vivid that it was difficult to believe they were not clouds; but their geometrical structure, and the fact that Venus would shine perfectly through them, quite discountenanced the idea of a cloudy origin. I noticed this particularly on 10th October, 1880; but the streamers were not seen regularly, or of the same intensity on different nights.

Perhaps some of your enlightened correspondents can say what is the cause of these streamers. I have never been able to satisfy myself on the subject. Are they due to clouds below the visible horizon through interstices of which the sun's rays are refracted? If so, why should they always appear pink? Or are they due to aqueous vapours in the upper regions of the atmosphere? They are quite distinct from either the "pink glows" or Zodiacal light.

Woolwich, Oct. 16. **E. E. M.**

PARALLAXES OF STARS.

[26391.]—IT will be remembered that the distinguished American observer, Prof. Asaph Hall, published in 1882 a volume containing the results of the parallaxes of Vega and 61 Cygni, which he had found by using the 26in. refractor at Washington. The results he arrived at were + 0·1797″ for Vega, and + 0·4783″ for 61² Cygni; corresponding to light distances of 18·11 and 6·80 years respectively. Prof. Peters, of Clinton, U.S., having pointed out that the correction for temperature to the value of the screw had been applied with the wrong sign, Prof. Hall undertook another investigation with the same instrument, the results of which, together with his determinations of the parallaxes of the ternary star o^2 Eridani and the double star Cygni 6 (Σ 2486), have just appeared as Appendix II. to the Washington Observations for 1883. For both stars the values now found are smaller; that of Vega, from observations extending from May 24th, 1880, to July 2nd, 1881, and comprising 128 different observations, is + 0·134″ ± 0·0055″; and that of 61² Cygni = + 0·270″ ± 0·0101, from 101 observations extending from October 24th, 1880, to January 26th, 1886. This latter value is much smaller than most modern determinations. Otto Struve found + 0·509″, Auwers + 0·564″, Sir Robert Ball, + 0·467″ and + 0·465″. All these are, of course, *relative,* not *absolute,* parallaxes, and some of the discrepancies between the observations may be due to the employment of different comparison stars. It is curious that since the time of Bessel (whose final result was + 0·348″) the parallax seems to have increased, until these latest results of Hall's have again reduced the value. His parallax answers to a light passage of 12¼ years. The only good absolute value of the parallax is that found by Dr. C. A. F. Peters in 1846 from observations at Pulkova, and is fixed by that astronomer at + 0·349″, curiously similar to Bessel's final value. This would give a light passage of just under 9½ years. All modern observations of the parallax of Vega agree very fairly, Hall's corrected value giving a light passage of 24¼ years. The only previous determination of the parallax of o^2 Eridani, a ternary star of long period and large proper motion, is Dr. Gill's, who, with the heliometer at the Cape, found a parallax of + 0·166″, answering to 19·9 years' light passage. Prof. Asaph Hall finds a parallax of + 0·223″, agreeing very fairly with Dr. Gill's; the time taken by light to reach the earth from that star being fifteen years. The orbit of the close distant pair of this wonderful ternary star has been computed by Mr. Gore, who seems to have succeeded Dr. Doberck in Ireland as a successful calculator of the orbits of binaries. He finds a period of 139 years, the masses of the two small stars being together about equal to that of the sun. The distance between the little pair and the great sun round which they

mutually revolve must be something like 380 times greater than that between the earth and sun, and the period something stupendous. The last parallax determined by Prof. Hall in this volume is that of the pretty pair Σ 2486, 6 Bode Cygni, which has an annual proper motion of 0·63″ (that of o^2 Eridani is 4·1″ a year). In the 5th part of the Dunsink Astronomical Researches Sir Robert Ball assigns a value of + 0·422″ ± 0·054 for the parallax of this interesting pair. He remarks, "It will be desirable that this result should be tested by other investigations. I propose to re-examine the question again. Pending the re-examination, I would regard the present determination of the parallax as merely provisional; though I think it can hardly be doubted that a parallax of very considerable amount really exists. It is impossible not to be reminded of 61 Cygni, which is in the same constellation, and has a parallax of 0·4676″ according to the discussion contained in the present Volume. It should also be observed that Σ 2486 and 61 Cygni are each doubles of the same general character, and have each a large proper motion." Prof. Hall, however, finds the parallax, from three different investigations, to be absolutely insensible, the first set giving a *minus* parallax of 0·094″; the second again a *minus* parallax of 0·137″; the third an exceedingly small positive one—viz., + 0·023″. The mean he assigns is − 0·021″ ± 0·0077″, from 54 observations between July 31st, 1883, and April 15th, 1886. It is impossible even to glance cursorily at Prof. Hall's investigations without being struck with the enormous amount of labour involved, and the care taken to exclude systematic and other errors.

October 18. **H. Sadler.**

EGYPTOLOGY.

[26392.]—In reply to "P." (26368), I assert that the Samaritan version is against him. It says: "The sojourning of the Children of Israel in Egypt was 430 years." Well, who were the Children of Israel? Why, the descendants of Jacob, of course—not the descendants of Abraham, as such. But suppose the Samaritan version did say otherwise, would that make Exodus xii. 40 and 41 correct? Certainly not. If the Children of Israel—that is, Jacob's descendants—*did not live* 430 *years* in Egypt, Exodus is clearly and unmistakably wrong, and yet "P." says they did not, and at the same time objects to me for not relying on the statements made.

"P." should compare the four generations before the Hebrews went into Egypt with the four spent in it. At the end of the first four the direct line through Jacob had 70 persons; add Esau's descendants (not followers), say 1,000; add also 2,000 for Ismail (a liberal allowance truly), and so we find at the end of the first four generations 3,070 persons who might be called Hebrews. If instead of one Abraham there had been 35, the result would be a population of 107,450.

In David's time his census states that there were 1,300,000 men—about double the number mentioned in Exodus xii. 37—not to mention the "mixed multitude" that went with them; so when we compare the development of the people *before* or *after* their stay in Egypt, we find their rate of production quite different from what it is alleged to have been when there.

"P." insists on counting 20 generations instead of four; but, even on his own suggestion, he is wrong; as if we allow the length of life to be 100 (long enough, I hope), and each new generation to begin at 25 (his statement), the term for four generations would be but 175 years; but the time to be covered, I must insist, is 430 years, not 175, and the number of generations is only four, so I insist a discrepancy or error exists.

"P." appears to imagine that the second generation must not begin till the first; but that assumption is arbitrary, and, I think, plainly false.

"P." says, "if he insists on four generations, he is confronted by the increased length of a generation as set forth by 'Memnon'"; but as "Memnon" does not believe in the increased length of a generation, there must be some other answer, and that is that the statement *is not historical*, but merely vague and poetic, and cannot be dealt with as a scientific fact.

"P." should remember that the Shepherd kings had an army of 600,000 when driven out of Egypt, and that a tradition may have remained of that number among the Israelites. If the Israelites were left after the shepherds departed, they cannot have been very numerous. Their numbers may have been added, too, when Rameses II. occupied Palestine, and these captives may have been those who had to do brick-making, while the others may still have been shepherds, as they say they brought their flocks and herds out of Egypt, and it is hard to suppose the poor brick-makers had many flocks just then. That a considerable number escaped into the wilderness of Sinai (not then as much of a wilderness as now), and ultimately joined the main body of their countrymen in Palestine, is probable; but to rely on words or numbers seems wholly unsound. **Memnon.**

[26393.]—In reply to "Memnon" (26369), I would ask to be allowed to say—as to Numbers i. and iii.—that all human testimony is more or less imperfect. Testimony respecting what is alleged to be Divinely revealed is no exception to this rule; nevertheless, many important questions upon which life and death, and even the destinies of nations, hang have to be settled by such relatively imperfect testimony. To exclude the testimony of the Bible, which is the obvious design of "Memnon," on this account exhibits the bias of a party. Apply the same rule to the chaos of Egyptian history, monuments, and inscriptions, where it has been discovered that monarchs have effaced inscriptions and then put their own names to deeds and days which they have never seen, and of course we would be required to reject their testimony also, and with much greater reason. That the Hebrews should have handed down to us the genealogies we have received is very remarkable. That there are some links wanting is not remarkable. It becomes us to make the best we can of their testimony, and show fairness, not prejudice, in dealing with it.

I have given what Gesenius held in regard to the Hebrew generations. "Memnon" gives what he *imagines* he would hold. Suppose "Memnon" tendered his imaginations as evidence in a court of justice, what would be thought of it?

"Memnon" has here given us a perfect sample of the methods of the so-called "Philosophical and Critical School," which, by the way, is now on its last legs, and Strauss's theory the greatest of mythics.

No. 4.—"Memnon," by an oversight, makes me follow the Septuagint, which, if he looks again, he will find I do not.

My authority for the "about" in 1 Kings vi. 1 is Fairbairn's Biblical Dictionary.

No. 6. The absolute omission of all mention of Israel in Egypt, if such were the case, as it is not, would not be conclusive evidence against their being there. There are many illustrations of this. Goldsmith's "History of England" makes no mention of the Great Plague or Fire.

No. 7. Israel in Egypt is represented for the most part as living separate from the Egyptians, and as even being an abomination to them.

I may follow "Memnon" obversely, and write good authorities say that the early books ascribed to Moses are written in Hebrew, which show them to be copies of others of the very earliest date; but we have something more reliable than this to turn to. It is a good rule that questions must be settled by the best evidence which we have. In this case we have the following.

Tradition manifestly as ancient as the writings themselves uniformly ascribed the Pentateuch to Moses. The earliest Jewish writings confirm this tradition. The prophets are unvarying in their testimony to the same; Christ and all the writers of the New Testament bear an identical testimony. Josephus and all Jewish historians, as far back as they go, bear their unequivocal testimony to the authenticity of the Pentateuch. There is no counter testimony, traditional or historical, which is unaccountable, and it would seem impossible, if Moses were not the real author of these books. What has been adduced amounts to good proof and sufficient to establish such a fact in law.

The plain honest sense of Deuteronomy xviii. 2., and of the word "necromancer," is that of a person dealing with the spirits of the dead. This proves that Israel believed in a life beyond death, and this, be it observed, is the only natural immortality directly taught in the Old or New Testaments.

As to "Memnon's" idea of what it proves at the Captivity, that is only another piece of imagination of the philosophical and critical school, wholly unsupported by anything that would go for right evidence. I therefore beg to hand over to him the responsibility of *twisting words*, of which he speaks. **Ramases.**

October 16.

[26394.]—If the statements in the Hebrew Bible are followed (without troubling about the Septuagint) there does not appear to be any particular difficulty in regard to the generations, or the 600,000 men of twenty years old and upwards. The prediction is given to Abraham (Genesis xv. 13) that his seed was "to be a stranger and a servant in a land that was not theirs for four hundred years." And Stephen quotes the words again in Acts vii. 6; while the four hundred and thirty years mentioned by St. Paul (Gal. iii. 17) agree with the statement in Exod. xii. 40, 41) that such was the length of the sojourn of the Israelites in Egypt, and are, therefore, not to be understood of the whole interval from Abraham to Moses. The genealogies, which give only four generations in Egypt — as, Levi, Kohath, Amram, Moses (Exod. vi. 16-20); and, again, Judah, Zerah, Zabdi, Carmi, whose son Achan, in Joshua's time, stole some of the spoil of Jericho (Josh. vii. 1), appear on the face of it to be compendiums, in which a name is given for a century, and at the same time legal documents, showing who was the representative of each branch of the families of the chiefs or head men, because in the full genealogy of Joshua, given in 1 Chron. vii. 23-27, we find he was the twelfth in descent from Joseph; so that, taking the 70 persons who went down into Egypt with Jacob (leaving out the households and followers), and giving twelve generations, the 600,000 men of twenty years old and upwards are no more than ought to be. **Dens.**

RAILROAD FARES.

[26395.]—Looking over a file of the *Times*, I have noticed the following table prepared exactly twenty years ago (*Times*, 27th September, 1866). I am sure it would interest many other subscribers to see a similar table brought down to date, and to know whether or not Great Britain still retains its pre-eminence for high fares.

Railroad fares reduced to sterling per 100 miles.

RAILWAY SIGNALS.

[26396.]—"Libra" has pinned Mr. Stretton into a corner, and the latter is now trying by play of words to avoid a reply direct. I have, in support of my previous assertions, only to ask you to kindly publish the inclosed letter by Driver Edward Bentley, of 33, Stoughton-street, Leicester, which appeared in the official organ of the Amalgamated Society of Railway Servants on the 1st instant, in reply to a report by Mr. Stretton, which will clearly show that the latter's knowledge of signals at his native town is, if not extensive, at least peculiar. Driver Bentley says:—

"Sir,—With reference to the slight collision which occurred on the 8th inst. [Sept.] between Leicester and Knighton Junction, I should, with your kind permission, be glad if allowed space to contradict such gross falsehoods. Your informant says the starting signal was lowered to allow the train to draw forward. The driver put on steam, passed it, and also passed the advance starting signal, which stood at danger. Now, sir, I am in a position to state that there is only one starting signal at this point, and that was off, as admitted by your informant. Then, again, he says both signals, which the driver failed to observe, were obscured by smoke. I am able to give this a flat contradiction, as there was no smoke from a passing train. He says again that the porter saw the home signal, meaning the cattle dock home signal, and applied the continuous automatic brake. I say also this is false, for this brake cannot be applied without the driver knowing, unless the guard applied it at the same instant as I did myself, for a train can so quickly be brought to a stand with steam on, and in this case steam was shut off, and I, as driver, was prepared to stop, and would have done so had not the line been on the curve with a long carriage siding filled with the same been there. By inserting this you will greatly oblige."

Your readers are becoming familiar with the words "law," "solicitors," "libel," &c.; but they must not be misled. At the time Mr. Stretton asked me, through the English Mechanic, to reveal my address he had in his hands the letter I had written to another journal, and was fully aware of my address.

I have declined to take notice of any communication which does not come through a public journal, and must continue to do so.

G. L. Watkinson.

THE LONDON AND N.W.R. ENGINE CORNWALL.

[26397.]—At various times during the past ten years several correspondents of the English Mechanic have asked for some information

as to the working of the engine Cornwall, No. 173, of the London and N.W.R., but this has never yet been forthcoming. The engine itself is absolutely unique, being the only one in existence with driving wheels 8ft. 6in. in diameter, and since the alteration of the B. and E. engines (Nos. 2,001, 2,002, and 2,003), by reducing the diameter of the drivers from 8ft. 10in. to 8ft., Cornwall has the largest wheels of any locomotive in the world; consequently, a good deal of interest attaches to her performances, and I have often regretted that no details were given. "Itzaex" (whose long disappearance from these columns I greatly deplore) promised to send some, but they have never appeared.

I am now able myself to furnish a little information on this subject. During my visit to England last year I had several runs with "Cornwall." She was then stationed at Whitchurch, and was running between that place, Crewe, Shrewsbury, Chester, Birkenhead, and Manchester. Her best work was with the 2.15 p.m. Manchester to Crewe, 3.47 p.m. Crewe to Chester, 12.27 p.m. Stafford to Crewe, and 1.53 p.m. Crewe to Manchester. With the two first-named trains she easily maintained a general speed of 55 to 60 miles an hour after "getting into swing." The 3.47 Crewe to Chester is timed at 49 miles an hour to the ticket platform, and the 21 miles were run in 25 minutes, or at the rate of 50·4 miles an hour. With the 12.27 from Stafford, the distance of 24½ miles to Crewe was done in 29 minutes, including starting and stopping, or at 50·7 miles an hour, the ascent of the Whitmore bank being included in this run. Down the bank a speed of 70 miles an hour was reached. With the 1.53 from Crewe the first length of 17¼ miles to Alderley was accomplished in 19½ minutes, a speed of 70 miles an hour being attained. The engine was remarkably steady at high speeds; indeed, of the many express engines on whose footplates I have travelled at such speeds, I cannot remember any having been speedier than this old Cornwall, now within a few months of being 40 years old, having been built in 1847. Originally she had the boiler slung below the axles, but she was rebuilt by Mr. Ramsbottom in her present form.

I should add that in all the cases referred to above the trains were light, consisting of four to six coaches, and the engine invariably slipped excessively at starting. I never saw her on a heavy train; but her driver, who appeared a very intelligent man, assured me she had taken 18 coaches from Stafford to Crewe in 35 minutes. That, however, did not come under my personal notice, so I merely mention it in passing. The small tractive force of the Cornwall manifestly renders her unfit for heavy loads; but judging from what I saw of her work she ought to do well with light, swift trains on a level road, such, for instance, as the Liverpool and Manchester expresses. I heard, however, at Crewe that next time she needed heavy repairs she would be condemned and placed in a museum as an interesting relic.

Wellington, N.Z. **Charles Rous Marten.**

BODIES FALLING FROM TRAINS IN MOTION.

[26398.]—MR. STRETTON may have experimented with heavy bodies falling from trains in motion, and if he would give the results they would be most interesting; but he surely is wrong in his explanation of the cause of the body not falling on the footboard immediately under the window from which it is dropped. The second law of motion, suggested by experiment, may be thus stated: "A force acting upon a body in motion will produce the same effect on that body in its own direction as if it acted upon the body at rest." I maintain that if the train were running in vacuo the body let fall outside the window would continue to move forward as fast as the train until gravity had brought it to the ground or the footboard, since the body, before being dropped, had the same horizontal velocity as the train and the force of gravity acting in a direction perpendicular to it could not alter this. When, however, the train is moving through the air the resistance of the air does decrease this horizontal velocity. Supposing the body falls 4ft., the time occupied by this would be a little less than half a second. If the train is running at 60 miles an hour, in half a second it would run 44ft., and the falling body, neglecting the resistance of the atmosphere, would move forward 44ft. while it fell 4ft. under the action of gravity. Experiment alone could determine if the resistance of the atmosphere would reduce this 44ft. to 42ft. It is possible that it might; but I am quite sure that any retardation there is, is due entirely to the resistance of the atmosphere. When the body is dropped inside the compartment, there is no horizontal resistance of air to overcome, as the air is also moving forward with the same speed as the train.

T. Perkins.

[26399.]—IT is a well-known and ascertained fact that bodies let fall in vacuo, while upon moving objects, drop quite similarly to what they would do if object they were on were at rest. During the passing of an object from a railway carriage window to the footboard, the air and variation in the speed of the train could alone cause rearward motion—that is, if the object were simply dropped. The possible alteration of speed in a train going fast could but cause a minute divergence. An object in contact with the footboard would probably rebound at an angle about equal to the angle of incidence, and this might increase rearwardness. A simultaneous upward jolt on the part of the carriage would considerably aid it, as would also a rising gradient. If a train ran for some time on the level, after dropping of object, the latter would shake down to lowest level on footboard, the which might be a hollow to the rear. If, again, the train were going up an incline, or the average journey were upwards, the object might take up a rearward position in excess of the result of a simple fall. **Vulcan.**

[26400.]—I CHARITABLY supposed that the suggestion on p. 115 [that the laws of falling bodies (by which I understand the action of gravity) would retard the forward motion of a falling body so that if dropped from a carriage window on to the step it would fall behind the window instead of directly under it], was a mere slip of the pen; but it seems that such is really Mr. Stretton's opinion on p. 155.

I do not for a moment question the possibility, or rather the probability, of a body having attained a position of rest on a railway carriage-step remaining thereon; in fact, I should be rather surprised if it fell off, unless very small or adapted to roll.

A train is generally moving pretty rapidly through the air, so producing what is popularly called a wind, moving backwards relatively to itself—this is what I meant when referring to the "wind"—though it would, perhaps, be more correct to speak of the train moving relatively to the air.

The resistance of this wind is considerable, as may be ascertained by holding a hand outside the window of a railway-carriage in rapid motion, and this "wind," i.e., the resistance of the air, and nothing else, Mr. Stretton, is the sole cause which could make the pistol fall on one side or the other of a spot on the footboard plumb with the point from which it was dropped. I say one side or the other, for if the wind were blowing in the same direction as the train and a little faster, the object would fall in front of the spot on the footboard which I have mentioned.

If the wind were travelling at the same speed as the train, the pistol would fall plumb on to the step, unless it were diverted by the eddies always accompanying a train in motion.

That this is so may, of course, be shown by dropping an object inside a carriage. The air then offers no resistance affecting the direction of motion, as it is moving with the carriage, like the wind in the last example. The object, if the train is moving at a uniform pace, will fall in precisely the line it would traverse were the carriage at rest.

Without trial, I cannot say how much the wind outside the carriage would displace the object as it fell; Mr. Bennett (page 157) might try the effect of dropping a piece of stick from a carriage window. A walking-stick held out of a window is far from offering no resistance.

In conclusion, as Mr. Stretton hints that he may have to give evidence on this subject, I trust that he will first read up the subject in some elementary book of mechanics. See p. 25 of Goodeve's "Principles of Mechanics," 1885 edition, for instance, where the very question is discussed, and the motion shown to be the same as I have stated, if the resistance of the air is left out of account.

It would be interesting to have particulars of the practical experiments to which Mr. S. refers.

Glatton.

LAUNCH ENGINES.

[26401.]—IN replying to Mr. W. H. Taylor (letter 26348) I hope he will not think me discourteous when I say that his design is very poor. As mentioned by "Engineering, Manchester," the type (if, indeed, it may be termed a type) of compound engine with two h.p. and one l.p. cylinders has never given good results, and is very rarely met with. The reason is that the back pressure on the h.p. pistons is very great, and the steam being taken in "snatches" from the receiver tends to make the turning irregular. But with one h.p. and two l.p. cylinders admirable results have been obtained. In this type, owing to the instant "draw" on the receiver, the back pressure on the h.p. piston is greatly reduced. This type of engine has been extensively adopted in the Atlantic steamers such as the *Etruria, Umbria, Servia.* With regard to altering your engine, by all means add a condenser. This will give you a substantial increase of power and economy. And if you wish to compound the engine the best way will be to add two new cylinders 3in. in diameter, and use them as high pressure, retaining the present ones for low pressure. But remember your engine will, theoretically, be rendered no more powerful by compounding, and the only advantage you will obtain practically is a little economy. I cannot recommend you to compound your engine, as I am sure you will be disappointed. I cannot make out from your letter what your boiler pressure is. Remember 60lb. to the square inch is the lowest that will work even a condensing compound engine with economy; pressure of 80lb. is desirable. So far as I can judge from your letter, the addition of a condenser to your engine can easily be made, and I would advise you before altering the engine any more, to see if the condenser will increase its power sufficiently. If not, then publish your address in the "E. M.," and I shall be very pleased to help you again. **G. D. Seaton.**

NON-CONDENSING ENGINES v. CONDENSING ENGINES.

[26402.]—MANY thanks to "Engineering" for noticing my letter. I may say that the idea I had with regard to compounding those two high-pressure cylinders by one low-pressure seemed (from a theoretical point of view) very fair; but as "Engineering" has tested the thing practically, and found it to fail, I must bow to his decision. But at the same time I should be very glad if he would point out the particular points of failure in the system. With regard to placing one high pressure between two low-pressure cylinders, in the case under consideration, it could hardly be done, for the two 6in. high-pressure are fixed very close together on one framework, and any alteration in that direction would be very expensive. In putting the 3in. cylinders on top of the 6in.—that is, an ordinary compound (if I understand it correctly), there would be no gain of power from the existing high pressures, but undoubtedly an economy in fuel. The triple expansion type of engines is a very good idea, but in my case the boiler is only capable of carrying about 80lb. pressure, so it would hardly be capable of driving a pair of triple expansion engines economically.

In re your remarks on compound non-condensing v. high-pressure engines, I have no doubt the non-condensing compound has some advantages over the high-pressure in a greater expansion of steam. But at the same time I doubt whether the advantage is sufficient to cover the extra machinery. Another thing is, you are bound to exhaust your steam above the atmospheric pressure; but if you made your engine condensing you could expand your steam down to 3 or 4lb. pressure, and thus gain so much additional work.

Middleton Junction. **W. H. Taylor.**

THE THREE YEARS' HIRE-PURCHASE SYSTEM.

[26403.]—YEARS ago I advocated this means of acquiring instruments in your paper, and you most kindly and elaborately figured some of Mason and Hamlin's for me. The times are much changed since then, and I would not advise anyone now to pursue the same course. You get 25 per cent. off for cash, and as a three years' customer they kindly put it on. The answer is, The trade must be considered. Well, just now the Canadians have been exhibiting, and there is a fine opportunity to use their advantage in this direction with great development of the hire system, and break through the trade fetters, compelling those who have had a long innings to come down a bit. Money is the consideration with all music people; they might have thousands of instruments housed, instead of warehoused—lying up in ordinary until a changed fashion, by a changeable public, compels a change of front.

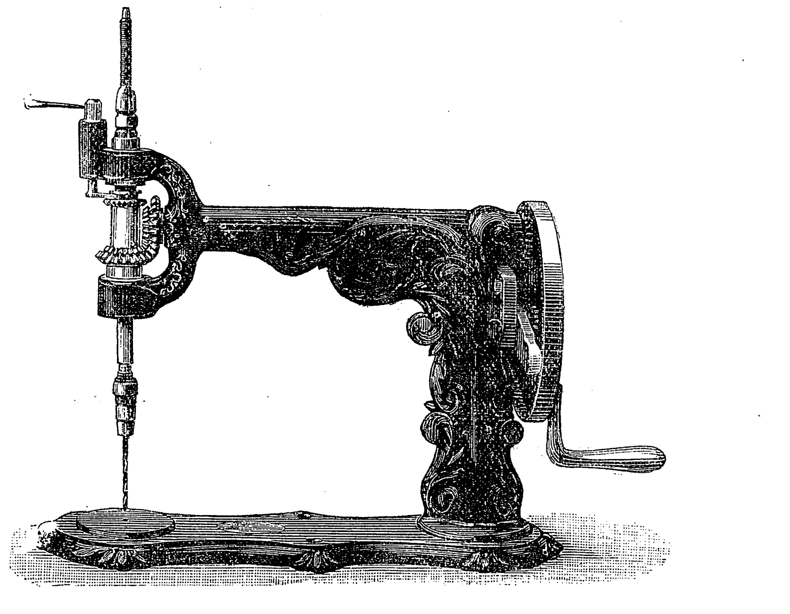
Coalitions in trade can be broken, and venturesomeness is characteristic of the age. It won't do to mend your ways when the Philistines are upon you, so this is a word to all and each.

H. Ussher, B.A., M.B., Surgeon.

BELLADONNA AND SCARLET FEVER.

[26404.]—I SHOULD like to communicate to your journal the great value of Belladonna in preventing the spread of scarlet fever.

There are four little ones in our family, and the eldest was taken with this malady a month ago. Being practically impossible to isolate the other three, I gave them each a drop of the first decimal attenuation in half a wineglass of water night and morning. The patient (treated with the same principally) had a favourable recovery, and the rest are happily showing as yet no signs of the fever, although within its influence day and night. This might be of present or future service to readers of "Ours." Scarlet fever is very prevalent with us just now, and, contrary to our case, is invariably going through entire families when it has once secured an entrance. **Xavier.**



A SELF-FEEDING DRILLING MACHINE.

[26405.]—THIS machine is designed to meet a want long felt by model makers, watch and clock makers, engineers, amateurs, and others, especially where great accuracy and rapidity are required. It will drill holes from $\frac{3}{8}$in. down to the smallest size without fear of breaking the drills; it is self-feeding, and has fast and slow gear to adapt it to the size of the drill. This machine is the only one in which the rising and falling of the drill, as well as the feed motion, are effected by the driving wheel alone, thus leaving the left hand entirely at liberty to adjust the work. It is made with ornamental iron base and arm, gun-metal head, wheels, and fittings, steel spindles and adjustable chuck to take either twist, fluted, or flat-point drills; and as all parts of the machine when at work move in the same direction, the wear and tear is reduced to a minimum. Its action will be understood at once, as all the movement required is the to-and-fro motion of a lever to adust the drill spindle, and the driving wheel for drilling.

F. Greenaway,
Patentee and Sole Maker, Slough.

LATHE MATTERS.

[26406.]—"Two heads are better than one," especially when the one is mine and the second is "Vulcan's." I am obliged to him for pointing out the slip I made in the eccentric motion of the star-guide. As he says, the handle must be attached to the eccentric and not to the strap; also in line 31, page 78, the word "reversing" should be traversing. On page 121 the "end view" shows (at the right-hand end of the traverse slide where the letter *b* occurs) the bearing supporting the end of the screw projecting below the bottom surface of the traverse slide; it must not, however, project, as it would catch the bed.

Most of "Vulcan's" remarks appear to me just, and I could myself add other objections; but though I feel their weight, it is not so easy to avoid them without falling into other and worse difficulties, and the whole design is nothing but a series of compromises. I will take up "Vulcan's" first letter on page 155, as shortly as possible, to save space. Will "V." kindly give sketch to show how he would cover the exposed part of front bush? Yes, I think the splits should be filled with something slightly elastic—say leather. I do not hold much to the flange fitting for mandrel, and would about as soon have the Edmunds model. I like the idea of the spring-tempered mandrel very much, and for my part should be satisfied with bellmetal bushes, which I think we could easily make and renew ourselves.

Taking now the objections in the second letter. (1) The reversed slides: I quite agree with these remarks; yet, on the whole, considering that the two slides of the upper rest may be *quite short*, owing to the convenience of the long under one; considering, too, the convenience of having the screws covered, and the great ease with which the slides can be taken apart—namely, by simply winding back the handles and then pulling them out—that, in this case, they are the best form. (3) Yes, the gib would be rather better the other side. I tried it there first, but altered it because there seemed hardly room to get at the tightening screws of the slide below. Of course the top slide has to be screwed back to get at two of them; but that is easy enough. (4) The ball-turning arrangement was part of the original design. I had lost sight of it, and am glad to have it recalled. (5) My idea is to have the lathe a short one—say, 3ft. 6in. or 4ft. bed, it being intended for fine metal work, including milling and ornamental turning. Of course it need not be short, but long turned shafts, &c., are about the easiest things to put out; it ought, I think, to be long enough to turn a wicket or a table-leg, though that is not quite the work it is intended for, but rather short work done close up. (6) The objection to the single clasp-nut is, of course, quite true; but few, indeed are the lathes with more than one. (7) I think it would be an improvement to make the lower V of the front slide flatter, because it would throw less strain on the screws of gib. I would also make the upper V sharper if it did not too much increase the difficulty of getting at it to get up the surface with scraper. I think the upper one might be made to 45°, instead of 60°, and the lower to about 75°, if that is thought worth while. (8) The sharp edges of the front V's are only $3\frac{3}{4}$in. apart; but it seems hardly fair to take that measurement: I would rather measure from the top corner of the front slide to its bottom edge $5\frac{1}{2}$in. There might be a counterweight hung on at the end of long slide in turning large diameters; but I hope that would not be necessary, especially as the mandrel is only designed and speeded for metalwork up to about 6in. diameter. It is a $4\frac{1}{2}$in. centre lathe, with head-stocks packed up to 6in.. to make room for milling underneath the cutters.

I am in hopes that some of your readers may be willing to join me in a set of planed castings for a lathe of this description, so as to save expense. If only we can agree upon the main features of the design, we might, I think, manage the drawings and patterns between us, and call it the "ENGLISH MECHANIC Lathe," supposing that you, Sir, do not object. There is, of course, no hurry about this, and even if the project ends in nothing but controversy, we shall still learn something.

I forgot to mention amongst the advantages of the vertical slide, that it allowed of a casting to be bored with a bar being bolted upon the milling bed, and adjusted to height by the screws without the very tiresome lining up and fixing with blocks, &c., usually required. The ornamental rest would go on where the metal turning rest is seen, and its screw would gear with the Hooke joints and upper wheel-plate. I should myself prefer the Captain Dawson rest, and this with the geometric chuck in combination would produce patterns and curves *ad infinitum*.

I was much pleased with the device sent by "Simplex" last week (page 132) for setting over the back-centre in turning taper; it is indeed simple. Does he never find it turn round? I should think if the centre were thrown out much it might be liable to do so; and if I make myself one, I should add a tail from the bow to reach down between the shears of the bed.

F. A. M.

HORSEPOWER AND MEAN-PRESSURE DIAGRAM.*

[26407.]—I SEND for publication a diagram which will, I think, facilitate the solution of many queries as to the effect of proposed alterations of cut-off, boiler pressure, &c., which appear in your columns.

I will premise that, given two engines by two makers with the same piston speed, cut-off, and boiler pressure, although the pistons may be of the same size, the power will often vary considerably.

The losses by friction, radiation, &c., are, however, fairly constant for engines of the same general design by the same maker, so that, having found by comparison with the diagram that the latter gives results, say, $1\frac{1}{4}$ time as large as those actually realised, a designer could always estimate his dimensions of cylinder as if for an engine $1\frac{1}{4}$ time as powerful as the one in hand, with some certainty of obtaining a sufficiently near approximation. I do not give the number $1\frac{1}{4}$ as having any virtue: the multiplier will vary from 1·06 (a compound jacketed engine described on p. 276-7 of Vol. XLI. *Engineering*) to $1\frac{3}{4}$ or more.

The diagram gives the same results as column 6 of Table B on p. 292 of Rules and Tables, or the table on p. 129 of your 43rd volume.

Description of Diagram.—To the left is a small scale of back-pressures. I have carried the lines for 18lb. and 5lb. back-pressure quite through the diagram, assuming these to be average values for high-pressure and condensing engines respectively. For any other back pressure the scale will give the height at which the line should be drawn or imagined.

On the right-hand side is a column of figures from 0 to 200lb., representing the pressure of the steam as it enters the cylinder in pounds per square inch *above* the atmosphere (the pressure of the atmosphere being here taken at 15lb. per square inch), being, if the steam-pipe be short and large, the pressure shown by the gauge upon the boiler.

The sloping lines correspond to these various pressures. The vertical lines indicate different points of cut off and rates of expansion, as shown by the figures below the diagram. There is a scale for finding the mean pressures with *any* piston-speed, and another for measuring the theoretical horse-power per square inch of piston *at a standard piston-speed* of 1,000ft. per minute.

For any other piston-speed, multiply the standard horse-power by the actual speed, and divide by 1,000; or, what is the same thing, multiply by the piston-speed and strike off the last three figures as decimals.

I suppose it is scarcely necessary to note that the piston-speed = revolutions per minute × twice the stroke in feet.

Example.—It is required to find the theoretical H.P. per square inch of a piston running at 1,000ft. per minute, steam-pressure being 100lb. = (100 + 15 =) 115lb. absolute, the back pressure 18lb., and cut-off at half stroke.

At the intersection of the line representing a back pressure of 18lb., with the vertical cut-off line for $\frac{1}{2}$ stroke, place one leg of a pair of dividers, and measure the distance up this latter line to the point where it intersects the sloping steam-line for 100lb. steam pressure. (See small sketch to the left.)

With the dividers so set measure the distance between their points on the H.P. scale, and it will be found that the power so read is 2·4H.P. for each square inch of piston, so that if, for example, the piston area was 10 square inches, the theoretical H.P. would be $10 \times 2{\cdot}4 = 24$.

If, without shifting the dividers, they are applied to the pressure scale, they will indicate 79·31b. mean *effective* pressure. Of course, the mean *absolute* pressure may be found, if desired, by measuring, in the first instance, to the bottom of the diagram or line of no back pressure, and using the pressure scale, which will give 97·3lb. absolute mean pressure (= 79·3 + 18).

If the piston speed in the above example were 600ft. per minute instead of 1,000, the power would be $2{\cdot}4 \times \frac{600}{1000} = 1{\cdot}44$ H.P. per square inch.

In a compound engine the number of expansions

$$= \left\{ \frac{\text{area of l.p. piston}}{\text{area of h.p. piston} \times \text{cut-off in h.p. cylinder}} \right\}$$

the stroke being equal in both cylinders. If the stroke is unequal, substitute "volume" and "cylinder" for "area" and "piston" respectively in the formula.

The power is theoretically equal to that of an engine with a single cylinder, equal in size to the l.p. cylinder, in which the steam is expanded the same number of times as in the compound engine with the same percentage of waste of heat. Example: —What is the theoretical power per square inch of the low-pressure piston of a compound engine in which the area of the l.p. piston = three times that of the h.p. piston, the steam pressure being 150lb., the piston speed 700ft., back pressure 5lb., and cut-off in h.p. cylinder = $\frac{1}{2}$ stroke?

The diagram, measured on the vertical line for $(3 \div \frac{1}{2}) = 6$ expansions gives 2·175 H.P. per square inch of l.p. piston at 1,000ft. per minute, or $2{\cdot}175 \times {\cdot}7 = 1{\cdot}52$H.P. per square inch of l.p. piston at a speed of 700ft. per minute.

For those who use slide-rules the following will be found convenient, calling the four scales A B C D, as usual. Below the gauge-point 1·273 on A, place the H.P. per square inch on B. Below the required H.P. on B find the required diameter of cylinder (the l.p. cylinder in the case of a compound) on D.

Suppose an engine running at a given piston speed, and cutting-off at $\frac{3}{4}$-stroke, gives out a certain horse-power, the steam-pressure being 70lb.

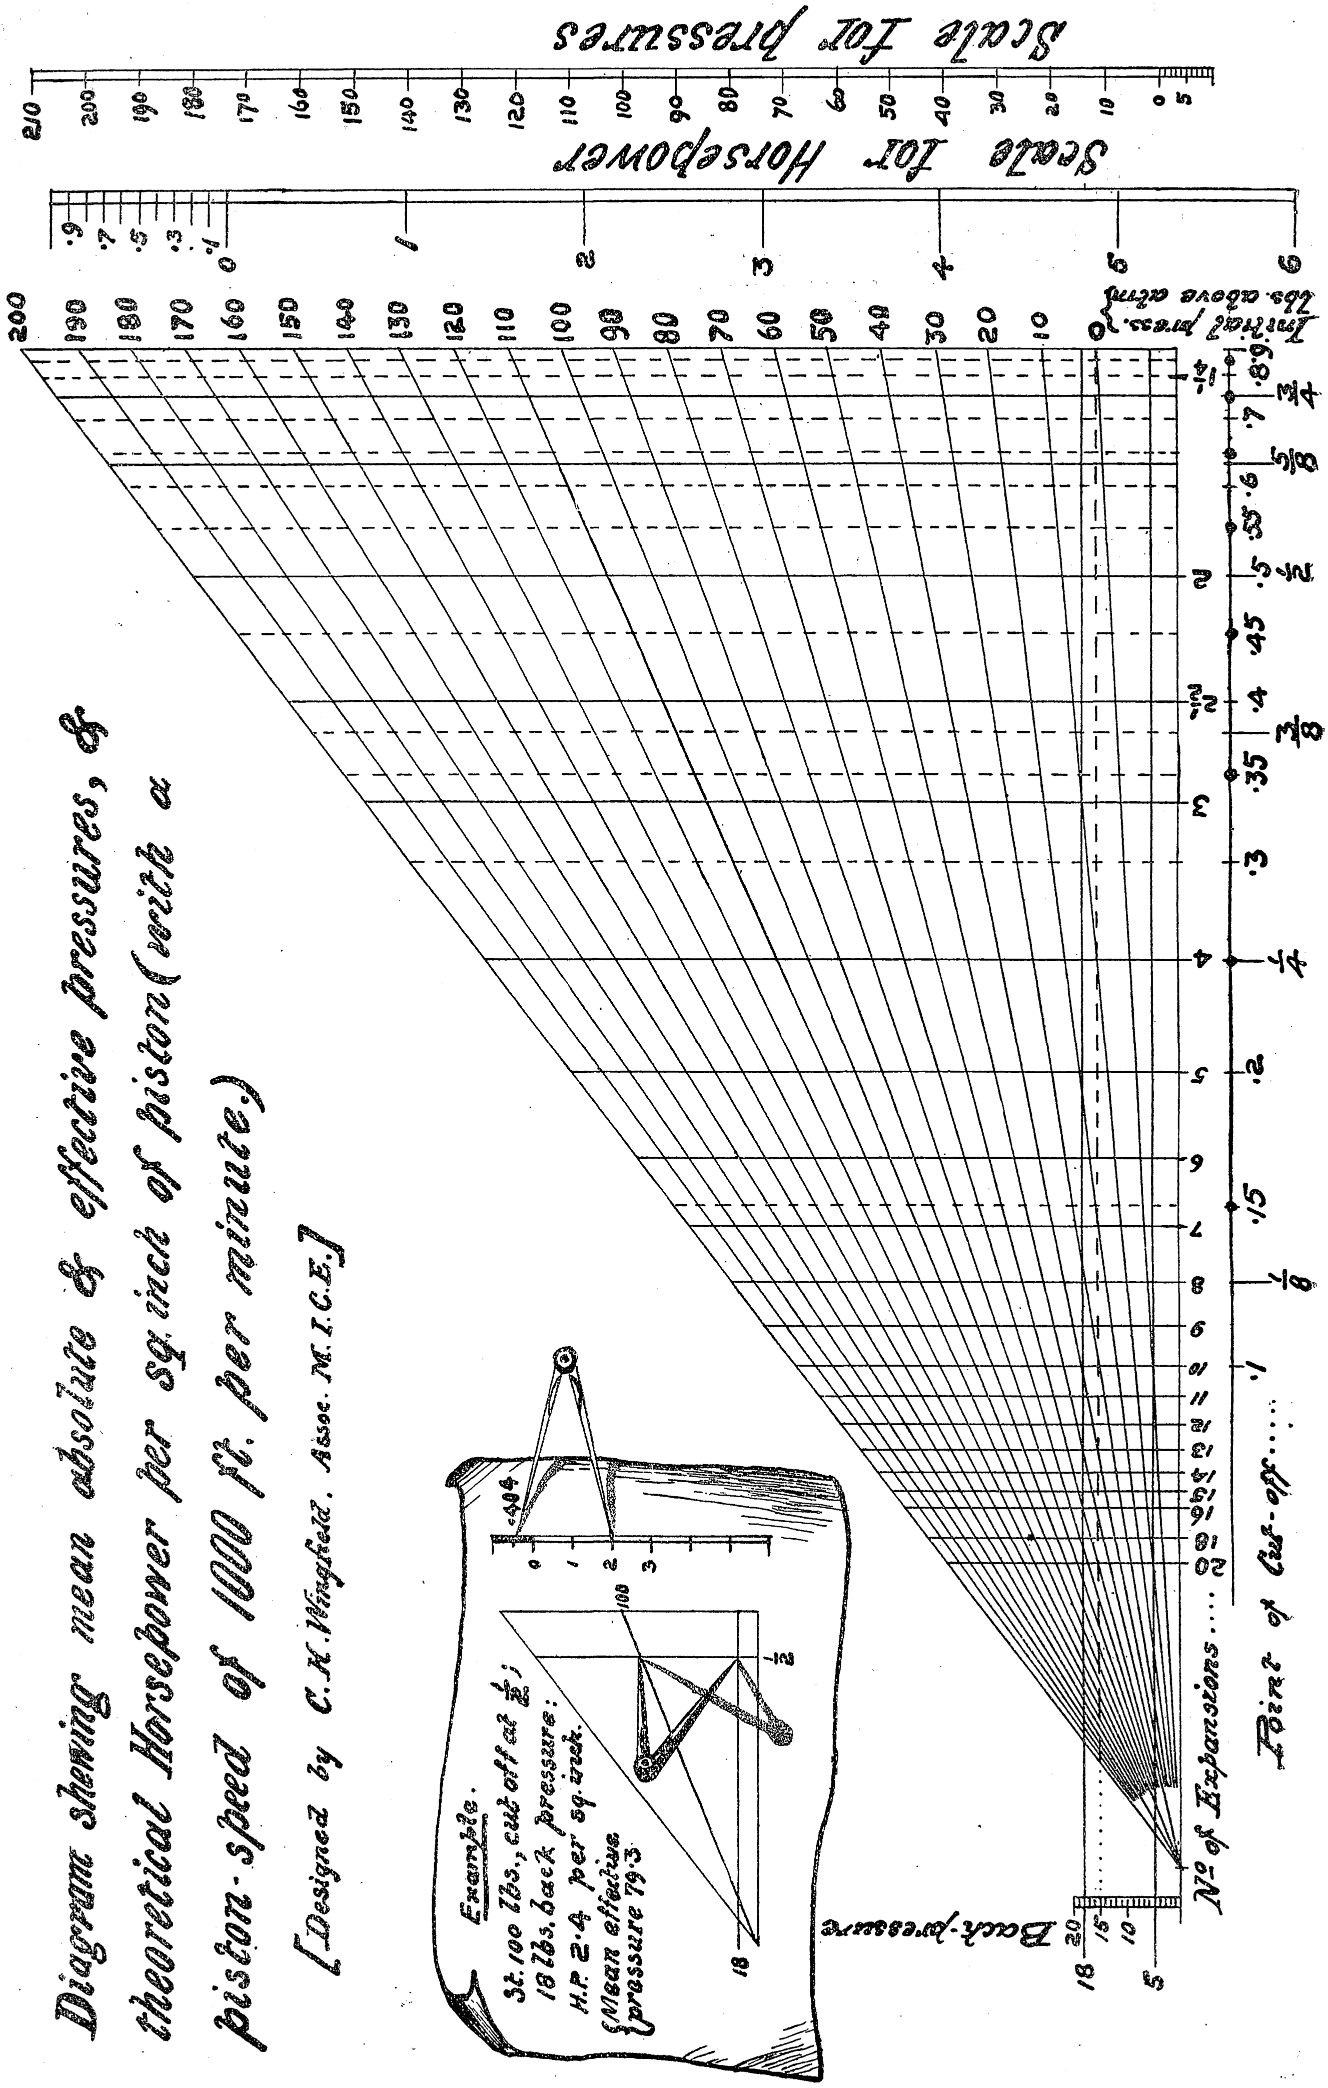


Diagram shewing mean absolute & effective pressures, & theoretical Horsepower per sq. inch of piston (with a piston-speed of 1000 ft. per minute.)

[Designed by C. H. Wingfield. Assoc. M. I. C. E.]

and the back-pressure 15lb. It is proposed to reduce the back-pressure to 5lb. by adding a condenser, and it is required to ascertain the point at which steam should be cut off in order to obtain the same effective mean pressure and horse-power as before, the piston speed being unaltered. Measure along the vertical line for ¾ cut-off the distance between the steam line for 70lb. and the back-pressure line for 15lb.; place one leg of the compasses, so set, upon the line of 5lb. back-pressure, and, keeping the other point over it so that a line drawn between them is parallel to the cut-off line, move the compasses towards the left till the upper point touches the pressure line for 70lb. steam. Both points will be upon the line for ½-stroke,—the required point of cut-off.

If, instead of adding a condenser, the back-pressure was still 15lb. and the cut-off made ½-stroke, a similar trial would show that the boiler-pressure must be raised to 82lb. in order to give the same power. **C. H. Wingfield.**

ON THE SUPERIORITY OF ZINC AND STEEL PENDULUMS.

[26408.]—YOUR correspondent, Mr. Christian Lange, commenting on my paper on the above subject originally published in the *Monthly Notices* of the Royal Astronomical Society, which you have thought worthy of a reprint in your columns, states that "Mr. Buckney compares a very badly-constructed mercurial pendulum to a well-constructed zinc and steel pendulum," and he further says that "such mercurial pendulums (as I used in my experiments) have been out of date many years."

I entirely deny the truth of both these statements, and I would call upon Mr. Lange to show, in your columns, when these very badly-constructed mercurial pendulums became obsolete, and to tell us what is the well-constructed form that has superseded them, and where it is in use.

Thomas Buckney.

SAFETY-LAMPS.

[26409.]—I AM glad to see that my letter has produced two replies. It would have been useful if a sketch of the testing apparatus had been given. Perhaps some correspondent will furnish one.

I notice that Mr. Shippey states that "there is only one really practical safety-lamp in existence"—viz., the "Morgan," and then farther on he admits never having tested the "McKinless" lamp. If he will write to the inventor, whose address is 1, Gore-street, Greenheys, Manchester, he will doubtless obtain the information he requires as to where to obtain a sample lamp.

May I inform "Nemo" that the McKinless lamp in the form I speak of never was submitted to the Royal Commission? That was an old and imperfect model. Again, why does "Nemo" omit to state that Mr. Morgan *failed to explode the McKinless lamp* at the Leigh experiments?

In the *Wigan Observer* of the 18th Sept. it is stated that "the McKinless was brought from Bickershaw Colliery. *It has no gauze.* Mr. Morgan did his utmost to explode it, but in vain."

Of course, it does not matter to me personally which lamp proves to be the best; but I simply desire to get at the facts, and also to see justice done. I notice neither of your correspondents answers my query *re* gauze. Perhaps they will kindly do so. I have always looked upon gauze with distrust, and gladly welcome any method by which we may get rid of it.

By the way, I was present at Mr. Swan's demonstration at Newcastle and heard his paper.

It only seems to be a question of time before we get an electric safety-lamp to give one candle power for 13 hours, and which will not weigh more than 3lb. **Henry Palmer.**

INDUCTION COIL.

[26410.]—A FRIEND of mine, an amateur, has recently completed an induction coil, the performance of which will, I am sure, interest a large section of the readers of the ENGLISH MECHANIC.

I saw the coil frequently while being made, and also since its completion, and it so far surpasses all I have previously seen that I venture to send you the following particulars.

The core is 14in. in length and 1½in. in diameter. The secondary has between 15 and 16 miles of No. 36 double-silk covered wire, wound in sections, and the usual spring brake.

One evening recently I saw it used with one bichromate cell (one zinc and two carbons) 5in. by 3in., and it gave sparks of 3½in., 4½in., 5½in., 6½in., up to 7½in., and it has since given, *with the same battery*, an 8½in. spark. When done with, the elements were lifted out of the solution and immersed in a jug of clean water, and with this it gave sparks 1in. in length, and a shock sufficiently strong to deter anyone from voluntarily getting a second.

With a view of seeing how small a battery would work the coil, a miniature battery, consisting of a silver thimble full of water and one drop of sulphuric acid and a little bichromate of potash, was employed, and with *it* sparks of 1in. in length were readily obtained.

So far the coil has not been tried with either Bunsen's or Groves's battery; but the great power obtained from such a small battery is, I believe, unique. **Joseph Marples**, Oxton.

CHAMBER ORGANS.

[26411.]—I HAVE read the kind letter by Dr. C. W. Pearce with feelings of pleasure, not unmixed with surprise. While I am free to admit that no one is better qualified to pass a reliable opinion on the quality and capabilities of an organ than Dr. Pearce, I feel sure that, in his panegyric on my Chamber Organ, he has been led away by his kindly feelings towards an amateur, who has, perhaps, had a little more heart than is usual in his work. Almost all the effects to which Dr. Pearce so graphically alludes were due to his own masterly manipulation. I have known organists who could produce better musical effects from a single *Dulciana* than others (skilful men) could from an *Open Diapason*. Dr. Pearce is of the former class; but, then, he is a sound musician, and an accomplished composer of music for "the king of instruments."

When I had the pleasure of entertaining Dr. Pearce, my organ was in an incomplete state—the Principale, 16ft.; Euphonium, 16ft.; Tromba, Clarinet, Oboe, and Viol-d'Amore were either out of the instrument or out of order—but all the appliances for the production of expression were complete, and I presume it is to the results obtained by their skilful use that he specially alludes. It is obvious that without the six very important stops above enumerated, the chief elements of grandeur and tonal balance were altogether wanting. Notwithstanding the Doctor's high opinion, I unhesitatingly say that my organ is far short of being perfect; so much so, that I have steadily declined putting its specification and description on record publicly.

I feel much gratified at Dr. Pearce's kind and flattering allusions to the articles on the Chamber Organ, which have appeared in these columns; and I cannot help thinking, as I read the second paragraph of his letter, it is a strange thing that at this late period in the history of organ building it has been left to a poor amateur, like myself, to say anything new or worthy of note on the subject of the Chamber Organ.

Organ builders, and, doubtless, many of the possessors of Chamber Organs of the class I have been compelled to condemn, consider my writings specimens of presumption and impertinent interference with matters beyond my province. Let them do so; and I shall be pleased if they can prove them to be uncalled for and unnecessary in the existing state of the art. Backed by such a man as Dr. Pearce, I feel that I have not been too bold in putting in a permanent form, through the hearty co-operation of the Editor of the ENGLISH MECHANIC, my "Notes on the Chamber Organ." That they are of interest to many at home and abroad is proved by my daily budget of letters, and the correspondence which has already appeared in these pages.

I have often wondered, after the manner of Dr. Pearce's wondering, on turning over the leaves of Dr. Wesley's charming "Pieces for a Chamber Organ," what sort of an instrument he had in his mind's eye when he wrote them. He could never have hoped, even with his cunning fingers, to render them in any worthy manner on the usual Chamber Organs of his day. I presume it has been the miserable condition of the Chamber Organ, generally speaking, which has discouraged the composition of more pieces of a similar class. Let us hope that the art of Chamber Organ building will now and henceforth be properly studied and developed, and that the pen of such a composer as Dr. Pearce will enrich the at present truly scanty musical literature of the Chamber Organ.

G. A. Audsley.

[26412.]—I NOTED Mr. Geo. Landel's inquiry in letter 26335, and the expression of a wish that someone would recommend him a good organ-builder. I would have replied to the question at once, but he gave no address. I beg leave to recommend Mr. David Pearce, 70, Gloucester-road, Regent's Park. This young man is *a genius.* Some ten years ago he was my page-boy. I lived then in Shropshire, and used to amuse myself with amateur organ-building.

This boy evinced such talent for the work that I had him apprenticed to Lewis, of Brixton. He is now working on his own account, and as I know how hard and yet how desirable a thing it is to get a good-tempered organ-builder, I am anxious for Mr. Landel to try my *protégé*, whom he will find not only good-tempered but clever and intelligent, and the neatest of woodmen—which is a great matter. At any rate, I trust Mr. Landel will call and see his work. I believe he has an organ just finished.

(Rev.) **T. A. Crowther.**

St. Joseph's College, Dumfries.

REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[60316.]—**Re Electric Time Ball.**—TO E. CONRY AND "GLATTON."—May I remind Mr. E. Conry of his promise to forward us drawings how to raise time ball by electricity, or, if he is busy just now, would "Glatton" oblige us? My object is to raise and let fall by electric current or clockwork. I do hope some one will come to my aid.—ORIGINAL QUERIST.

[60334.]—**Falling Bodies.**—"R. E. F." will see that the stone is retarded by the earth behind it, if he thinks for a minute; each particle of the earth attracts it, and it therefore goes slower than it would if the earth behind were not in existence. The stone has a horizontal velocity of approximately 1,000 miles per hour, decreasing by attraction of earth and an increasing vertical velocity; and as each of these depends on the distance from centre at any one minute, the solution is complicated (for me). I think it is an ellipse relatively to centre of earth; but perhaps a straight line relatively to the rotating earth, partly, at least.—M. YORK.

[60334.]—**Falling Bodies.**—Such discrepancies as "R. E. F." points out are exactly what, I should say, indicate utility in prolonging a discussion, instead of "no utility." On that I must differ *in toto.* The track of a body through the earth, regarded without reference to earth or plumb-line, but simply to the stars, would be an ellipse, and, of course, with the minor axis "Dubliniensis" says, and I presume it would keep revolving in the same ellipse—that is, one pointing always towards the same star. Meanwhile, as the earth and plumb-line move, the body's track referred to these, or regarding these as fixed, is a very different curve, one closely resembling, I fancy (if the passage through occupies, as he says, 40 minutes), a circular arc of 10°, with its concavity outward, and coming up vertically to the surface, not at the antipodes of its starting-point, but at longitude 170° E., then returning in a similar arc to 20° W., thence again to 150° E., then to 40° W., and so on, always missing the centre by 260 miles, and missing the antipodes by 10°, nearly thrice as much. I assumed the time of describing the ellipse to be equal to that in a circle, however small the minor axis; but it seems, from "Dubliniensis," it would be rather proportional to the length of path, or nearly so.—E. L. G.

[60342.] — **Green Stain for Furniture.**— Aniline green can be used, but the old-fashioned stain is made by putting, say, two ounces of powdered verdigris into a pint and a half of strong vinegar, adding a little sap green and a little indigo. Acetic acid and copper filings is a simple green stain for white woods; but this kind of "staining" is equivalent to dyeing, and any process employed for dyeing vegetable matter green will probably answer. Staining wood means, in the technical sense, making it to imitate the colour of some other wood.—NUN. DOR.

[60344.]—**Loco. Sand Blast.**—There cannot be any advantage in the use of the blast with the sand, if the ordinary pipe is properly placed; but it will be understood that the blast forces the sand directly under the tread of the wheel while the engine is standing, and so enables it to start, by giving adhesion at once without moving more than half an inch. Of course the driver or his fireman could do the same by getting down and placing the sand under the wheels.—J. T. M.

[60345.]—**Brakes.**—I suppose this querist has heard that some stock is fitted with both Westinghouse and vacuum brake appliances. That is for running with stock fitted with either.—J. T. M.

[60356.]—**Fitting Brass Bushes.**—Make them an easy driving fit.—C. K.

[60357.]—**Gulf Stream.**—Experiments of the kind named by the querist have been made many times, and it is probable that he will find an account of them in Lieut. Maury's works, as well as in the "Voyage of the Challenger." I regret I cannot give more definite information.—B. M.

[60363.]—**Phonograph Mouthpiece.**—This query, as stated, is rather incomprehensible. What, for instance, is meant by the "coil," and what can there possibly be difficult in the mouthpiece? Has the querist seen No. 683, p. 157? If not, I would advise him to procure that number.—A. T. E.

[60361.]—**Organ Accordion.**—You want first a stand, which may be anything you like so long as it is firm, and then a pedal with cord or lever to work the bellows. There is an illustrated description in No. 782, p. 42.—N. E. CHILD.

[60366.]—**Tile Setting.**—The tiles should be laid as closely as possible, and thin cement run into the joints where sufficient has not worked up. The base should be well laid and flatted, and then covered for a small area at a time with liquid cement; the tiles being laid in this, with their edges well wetted, will probably have sufficient between them; but if not, any crevices must be filled up. It must not be "swept" into the joints, but carefully applied, taking care to keep it off the face of the tiles.—SAXIFRAGE.

[60376.]—**Trumpet Stop.**—Better submit the obstinate pipes to an expert: there must be something wrong with them.—J. K. L.

[60377.]—**Breaking Strain of Cable.**—It is impossible to give a satisfactory answer to "Sailor's" first query; as to the second, books containing the working tested and breaking strain of hemp, manilla, iron and steel wire ropes and chain cables, together with the tonnage of vessel they are suited for, can be had at almost every bookseller's.—JAMES MCCASH GOVAN.

[60379.]—**Model Schooner.**—The suggested schooner is too small to be of any use even as a model yacht; but the querist will find "lines" which he can reduce in back volumes.—GALATEA.

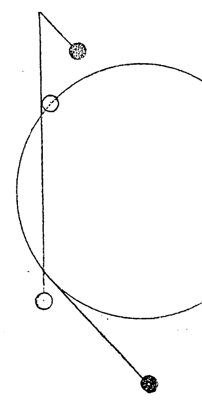
[60404.]—**Condensing Tube for Launch.**—You might do without an air-pump if proper provision for escape of air is made. I do not think you can make a launch-boiler to keep 100lb. steam without artificial blast of some kind; a fan, for instance.—GLATTON.

[60428.] — **Silvering Glass.** — Almost every back volume of the "E. M." contains some information about this. See p. 327, Vol. XXXI., for Mr. Brashear's process.—GLATTON.

[60430.] — **Gravity Daniell Cell.** — TO "WEALD."—I have read your reply again. If you will also read mine again (in. No. 1,123) you will see that I do not ask how there can be free acid present, but "whence the *gain* in free acid?" For you gave me the impression of believing that the solution became more and more acid as the result of electrolytic action in the cell. This is not the case; the free acid formed by reduction of copper sulphate merely makes up for the free acid consumed by union with the zinc. On the whole, we have no gain in free acid: we gain sulphate of zinc and we lose sulphate of copper; free acid as before. The only source of acidulation is from the acid in the crystals as prepared; and even in a saturated solution the proportion of acid is but small, and such as would constitute a very mild acid solution. Dilute sulphuric acid might be mingled much stronger than this (without copper salt) without causing hydrogen to be evolved from amalgamated zinc as in the gravity cell. I wrote my second reply not to obtain instruction, but because I thought your own reply was a little misleading to the querist; and unless you had made some theoretical oversight, imagining that the electric action gave rise to an increase of free acid, I am still at a loss to know how the solution could be or become "too strong in acid," so as to defeat the amalgamation of the zinc. If I am wrong in my conception of the case, you or Thompson or Guthrie or Sprague will do me a most important service in setting me right, as this would be delivering me from unconscious ignorance.—WEALD.

[60446.]—**Bisulphide of Carbon.**—TO MR. GREY, F.C.S.—I am grateful to Mr. Grey for his comprehensive reply to my first query. Perhaps he will allow me to put my second somewhat differently—viz., How much bichloride of mercury would it be necessary to vaporise so that the fumes should be equally distributed all over a room of the dimensions given—viz., 1,000 cubic feet, to the fullest extent possible? I should also like to trespass on his kindness further by asking another question as follows: If bichloride of mercury be vaporised by heat in a closed chamber, assumed to contain organic matter (germs, &c.), and bisulphide of carbon be at the same time burnt, would the sulphurous acid or other gases produced by such combustion combine with the vapour of mercury and prevent its action on the albumen of such organic matter, which is stated by Liebig to be converted (by the action of such vapour) into a compound of calomel and albumen. It seems evident that bichloride of mercury is rapidly taking the place of numerous other substances which have till recently been thought, or assumed to be, germ destroyers, and it is because I have seen contradictory statements published as to its action when vaporised in the presence of sulphurous acid, that I take the liberty of asking so esteemed a contributor as Mr. Grey the above queries.—IGNORAMUS.

[60434.]—**Crank Movement.**—I cannot give "T. C., Bristol," sketch of motion without making all known, as it is but a simple affair. I will, however, show him sketch of how he may obtain half a



circuit without dead point; and when he can complete the same and reverse the motion, he will know how it is as impossible to have a deadpoint as it is pronounced impossible to be without one. One end of beam is pivoted outside of balanced wheel in line with centre, resting at about two-thirds its length on small grooved wheel attached to rim of large one; balance weight on end of beam with one on large wheel. That is the problem I started with, and found by taking a short cut round the circle I got the same power in less time. —SCOTTY

[60434.]—**Crank Movement without Dead Point.**—It would not be difficult to connect a hand-lever with a crank so as to avoid a dead-point, e.g., by causing fulcrum to move in a sloping slot; but if you mean that your piston would keep its full speed up to the end of stroke, then suddenly reverse and start at full-speed back, I reply that the engine would probably shake itself to pieces in a short time.—GLATTON.

[60467.]—**Falke Torpedo Boat.**—The *Falke* was built by Yarrow and Co., of Poplar, London, for the Austro-Hungarian Government. She is built of galvanised steel, and is 135ft. long, extreme breadth 14ft., 9ft. deep, and 88 tons displacement. The other particulars, together with the diameter and pitch of screw, could only be ascertained from the builders, unless their sizes and distances could be worked out to scale from a drawing which, from the nature of his queries, I presume "Isle of Dogs" has. In any case, I do not see how it is possible for any one to make a model of a ship unless he has her "lines" to work from.—JAMES M'CASH GOVAN.

[60469.]—**Hygrometric.**—TO MR. WM. JOHN GREY, F.C.S.—I should be very much obliged if you would work out an example. Pressure, 739 millimètres; weight of air, 534·22 grains per cubic foot; also of the actual amount of moisture contained in the same. How does the great pressure of absolute moisture in Bombay, Calcutta, and Madras affect the wood of English articles manufactured of well-seasoned wood and metal combined, such as guns, &c.—POSTULATA.

[60484.]—**Twilight.**—I think "E. L. G." must have mistaken the point at issue, for I do not question the accuracy of his figures for a moment, but I maintain that for practical purposes they are quite useless. The theory that twilight lasts until the sun is 18° below the horizon is pretty nearly absolete now, nor is it necessary to go to the tropics to show how fallacious it is in practice. For instance, on October 17th twilight should have lasted about 110 minutes, instead of which it was considerably under an hour's duration. It would scarcely be more absurd to predict the amount of sunshine on any given day from the latitude of the place and the sun's declination! If "E. L. G." still doubts that tropical twilights are extremely short, I must refer him to the works of the celebrated Baron Alexander von Humboldt, especially those treating of the northern portion of South America. It is certainly rather strange to find "E. L. G." quoting "F.R.A.S." as authority for his statements, since "E. L. G." himself has commented on the "entirely fallacious way" that gentleman treated another problem (p. 553 of last Vol.) and as "a hundred-fold exaggeration would not surprise" him, might not "F.R.A.S." be wrong on this point also, even if his error were only ten-fold? I have to point out two errors in "E. L. G.'s" would-be correction to my definition of astronomical twilight; but as I suppose he will persist in them, as also in the correctness of the axis minor of his ellipse (p. 20) which is only 30,000 times too small, I make these corrections for the benefit of the querist. First of all, I did not write "the *first* sixth magnitude star," (whatever that may mean), but the "moment a sixth magnitude star appears." Then we are gravely told that it is the "faintest ones," but as these *are* sixth-magnitude stars, this is a distinction without a difference. Next, we are told that the spot selected is near the N. or S. horizon, and not the zenith, which is quite wrong, if we may believe Dr. Robert Mann, F.R.A.S., who says that the star is to appear in the sky directly overhead. Obviously, a star low down on the N. horizon may be obscured by mists long after another star of the same magnitude has appeared at the zenith.—R. E. F.

[60499.]—**Waterworks Pressure.**—In answer to "Niagara," the average pressure in Glasgow is 40lb. per square inch. Most probably some other correspondent will be able to supply the rest of the information you ask.—JAMES M'CASH GOVAN.

[60503.]—**Photography.**—I beg to offer my sincerest apologies to Mr. Bottone for having by an error in the name attributed Mr. Bennett's mistakes to him. Mistakes, however, they are; and if Mr. Bennett will look at any dealer's *recent* price list, he will find that I am not specially favoured in the price I pay for my plates—he or anyone else can now get "Ilford" or "German" quarter plates for a shilling a dozen. By Ilford, I mean those made by the Britannia Works Company, formerly sold by Marion as Britannia. The reduction in price was made, I believe, after the trial Mr. Bennett alludes to. Several other makers have reduced their prices within the last few months. Among the plates will be found Fry's "German." Hinton and Co.'s list is before me, from which I quote. It was sent to me in the early part of the summer.—T. PERKINS.

[60511.]—**Boys' Marbles.**—I fancy that the description of the manufacture of these, which I gave on p. 138, requires supplementing, thus:—The grooves in the lower stone are not only "circular" in plan, but shallow arcs of circles in section, and gradually of less width, or deeper, as they are nearer the centre. The process commenced in the outmost groove would be continued by moving the partly-formed balls from groove to groove as they advance towards true sphericity. At the same time, I may say that I have heard doubts expressed by practical men as to whether marbles could be produced by the process described. I think that after the preliminary roughing they would require to be treated a great many at once in a rumble or revolving cask to rub off the corners, and that it would be difficult even then to make them roll between the stones, unless there were grooves in the upper as well as the lower one. It is possible that glass might be similarly treated in, say, a copper grinder with emery; but I think only a rough approach could be made in that way to the accuracy required in a lens, and I should doubt the economy of the process, as, for making more than two at once, large spheres of glass would be required, and large masses of suitable glass are enormously expensive; then they would require not "splitting," but slitting—that is to say, cutting off from the mass with a lapidary's slicer, which would surely be much more expensive than taking a flat piece of plate, and rounding one side on a grindstone preparatory to figuring and polishing it. I do not remember ever seeing an agate "marble" with an even, smooth surface, though they are often highly polished. My recollection of them is that they bore all over the marks of the flat grinding disc on which they had been rolled about in all directions, and that these marks were at best only partly obliterated by the subsequent polishing on buff wheel, and sometimes not at all. Agates are, I believe, always treated singly. Since writing the above I met with half a dozen agates at the Soho Bazaar, after a voyage of discovery lasting two hours, and bought one of them to examine. It bears out what I said above, only more so, as it cannot compare for accuracy with even the common stone ones. As to boxing balls, my figure 212 is, of course, a mistake for 512; the sizes of boxes that I gave were puzzled at, more with a view to ascertaining how the peculiar number 501 was capable of being stowed away at all, than to demonstrate more or less close packing. I see I was wrong in stating that my box No. 4 is closer than No. 2, for No. 2 is 518 cubic inches, and holds 629; so No. 4, with 585 cubic inches, should, in like proportion, hold 710, whereas it does only hold 704.—J. K. P.

[60522.]—**Evaporation.**—From $\frac{1}{12}$th to $\frac{1}{10}$th of an inch per diem.—GLATTON.

[60525.]—**Bewitched Barometer.**—If "Bunting" is able and willing to write a few letters on the weather and how to forecast it, on the lines of his reply on p. 159, I am sure they would be of interest and use to many of your readers.—GLATTON.

[60529.]—**Polishing Paste.**—I purchased from one of the advertisers of recipes, in the Sixpenny Sale Column, the recipe for the German polishing paste, and found it exceedingly good, and a very great saving in cost. I do not feel at liberty to publish the recipe under these circumstances, but

no doubt it may be still obtained.—E. THEOBALD.

[60512.] — **Mathematical.** — "R. E. F.'s" answer to this involves an "unknown." I would suggest the following solution:—

For simplicity put 5 for a, and 3 for b, then—

$$\left.\begin{aligned} x^2 + y &= 5 \\ x + y^2 &= 3 \end{aligned}\right\}$$

$$\therefore\ x^2 + y^2 + x + y = 8 \ldots\ldots \quad \text{(i)}$$

$$\text{and } x^2 - y^2 + y - x = 2$$

$$\text{or } (x - y)(x + y - 1) = 2 \ldots\ldots \quad \text{(ii)}$$

Put u for $x + y$, v for $2\,xy$

$$\therefore\ u^2 - v + u = 8 \ldots\ldots \quad \text{(i)}$$

$$\text{and } \sqrt{u^2 - 2\,v}\,(u - 1) = 2 \ldots\ldots \quad \text{(ii)}$$

Squaring (ii) (and thus introducing roots which do not strictly belong to the original equations).

$$(u^2 - 2v)(u^2 - 2\,u + 1) = 4 \ldots\ldots \quad \text{(iii)}$$

But by (i)

$$u^2 = 8 + v - u$$

$\therefore$ Eliminating u^2 from (iii)

$$(8 - v - u)(9 + v - 3\,u) = 4$$

Eliminating v by $v = u^2 + u - 8$ we get

$$(16 - 2\,u - u^2)(u^2 - 2\,u + 1) = 4$$

$$\text{or} \quad u^4 - 19\,u^2 + 34\,u - 12 = 0$$

By guess—

$$(u - 3)(u^3 + 3\,u^2 - 10\,u + 4) = 0$$

$$\therefore\ u = 3 \text{ and then } v = 4$$

$$\text{whence } x = 2$$

$$\text{and } y = 1$$

—H. B. R.

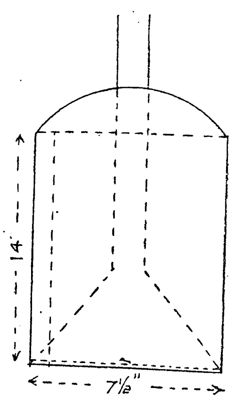
[60512.]—**Mathematical.**—There is a mistake in the solution given by "M.I.C.E., Bath," in issue of October 15. The series should be—

$$\pm\sqrt{b}\left\{1 - \frac{x}{2\,b} - \frac{x^2}{8\,b^2} - \frac{x^3}{16\,b^3} - \&c.,\right\}$$

and generally $\frac{x^n}{b^n}$, not $\frac{x^n}{b}$, as printed.—F. E. R.

[60533.]—**Crystal Slides.**—A few are described in Lancaster's "Half Hours with the Microscope," 2s. 6d.; and in Davies' "Preparation and Mounting of Microscopic Objects," 2s. 6d.—GLATTON.

[60548.]—**Copper Boiler.**—To "T. C., Bristol." —The above is what is described as a conical flue boiler; cylindrical in form, the joints are all



riveted with copper rivets. I herewith send you rough sketch.—A COUNTRYMAN.

[60548.]—**Copper Boiler.**—If very well brazed, and the ends of proper strength, which cannot be ascertained from your description, and if the boiler is round and of 7½in. diameter, the rule given on page 235 of Vol. XLI. gives a working pressure $= 500\,\frac{t}{d}$, where t = thickness, and d = diameter in inches. $500 \times \frac{\cdot035}{7\cdot5} = 23\cdot3$, or, say, 24lb. per square inch. In any case, you should not work the boiler under steam until you have tested it with cold water and a force-pump to fully double the intended working pressure. Your engine should run with 1lb. or so of steam, if not doing any work.—GLATTON.

[60557.]—**Honours Exam.**—The advice given by Mr. Bottone in last week's paper is very good. Do not, however, be frightened by his remarks about mathematics. I passed the exam. with only a very moderate knowledge of mathematics, and even that was not required to answer the questions. —L. M.

[60561.]—**Polish.**—The best way, to my mind, to ebonise and varnish, or rather to polish is this:—Get some gas black—this is easily got by hanging a flat piece of copper over a gas-jet, and I dare say you might obtain some at a coffee tavern, where they heat tea, &c., in copper boilers—and rub this on along with French polish in the usual way. "Colombo" might try this, and report.—GAS ENGINE.

[60577.]—**Preserving Apples.**—Make a number of shallow wooden trays (3ft. or 4ft. by 2ft. or 2½ft.) with latticed or open wickerwork bottoms. On these place a thin layer of dry straw. Place the apples singly, stem downward, on the straw, nearly touching each other. Stack the trays in an open-work wooden frame erected in a dry, well-ventilated room, where an abundance of cool air is always circulating. Keep out frost. Examine each tray of apples frequently, and pick out every apple that shows the least sign of decay.—G. E.

[60584.]—**Blueing Steel without Heat.**—Spades and axes are painted with thin lacquer coloured with Prussian blue. Is this what you want?—GLATTON.

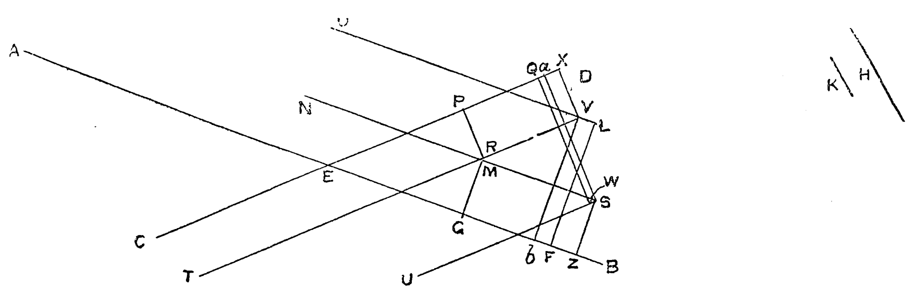
[60585.]—**Laying-in Cold-Water Pipes.**—Good brick or puddling clay free from grit must be obtained for this purpose. No oil is needed. Temper the clay by mixing with it a small quantity of water to a moist but non-sticky consistency. This can be done with a shovel on a board or other flat surface; afterwards knead with the hands, and compress until it can be worked through them in a tough but pliable roll. "Force Pump" says nothing about "packing." To do this, first lay in with a caulking tool a packing of spunyarn or oakum between spigot and flange to prevent the lead from running through to the interior of the pipe, seeing that it is placed a parallel distance all round. Now lay the roll of clay evenly round end of flange, leaving a hole at the top for the molten lead to be poured in. When this has set, remove the clay and hammer the lead in tight with a flat tool, afterwards cutting off with a chisel, flush with the end of the flange, any superfluous lead. This is far from a complex operation, but I should advise "Force Pump" to get an experienced man with the proper tools to make his joints, especially if his pipes are to stand much pressure.—GUILLAUME BOIS.

[60585.]—**Force Pump.**—In laying some gas-pipes with which I was interested, ordinary brick-clay was used, moistened with water, though I found that any clay would do. The lead should be poured in slowly, to prevent spurting.—W. C.

and hair-spring, and balance perfectly free, the watch should now take a good motion.—J. H. D.

[60591.]—**Hardening Spring Steel.**—Verily, my masters, we have here a most monstrous wittye forme of ye anciente British joake. Methinks ye sticke had been putte to hys propre use if diligentlye applyde to ye dustynge of ye sprynge-rubbynge springald. Seriously, someone appears to have been talking nonsense while professing to teach E. Hoare. Steel is usually hardened by heating to a bright red and suddenly cooling in water. It is then partly softened or "tempered" by being heated to a much lower temperature than before, and again cooled. For details of the process, vide back numbers.—SPRINGEE.

[60595.]—**Geometrical.**—To find a point such that the perpendiculars let fall from it on two given straight lines shall be respectively equal to two given straight lines, and also to determine how many such points there are: Take it for granted that A B and C D are of unlimited length, and also that they are not parallel; if they do not meet, produce them till they cross at point E. Let A B and C D be two given straight lines crossing at E. To find a point, or points, such the perpendiculars let fall from it on them to A B or C D shall be equal to the two given straight lines K and H, in E B take any two points—F and G. At the point F in E B draw F L at right angles to E B (Bk I. 11); at the point G in E B draw G M at right angles to E B (Bk I. 11), and make G M equal to K and L F to H; through M and L draw M N and L O parallel to E B (Bk I. 31). In E D take any points—P and P. At the points P and Q in E D erect P R and Q S at right angles to E D (Bk I. 11), and make P R equal to K and Q S to H; through R and S draw R T and S U parallel to E D (Bk I. 31). Produce T R to meet O L at V, and produce N M to meet U S at W (O L and U S produced, if necessary). Then W and V are two of points required. Through V draw V X parallel to P R (Bk I. 31), and through W draw W Z parallel to E B (Bk I. 31).



[60588.]—**Verge Watch.**—I think your escapement is too shallow; make it a little deeper by filing a shade off the dovetail and counter-potance. If this will not do, you should take it to a practical man, as there are a great many things to look to in repairing a verge escapement properly.—A READER.

[60588.] — **Verge Watch.** — The reason that your watch gains time is evidently that the escapement is shallow. Now, this might be cured by very simple means; that is if the watch kept time before. Pushing in the follower a little would likely do this, if such has been the case. But supposing escapement to be bad before it was cleaned, I will endeavour to tell you how to repair it. In the first place, if verge is much worn it might require a new one. But supposing it will do, first see that escape-wheel teeth are all of an equal length. If not, put collet on escape-wheel, and put in turns, and take a little off ends of teeth until they are perfectly "true." Now take balance-wheel file, and file teeth up to nearly a point again, being always careful not to touch the fronts of the teeth; but to take it off the backs, thus—/|. Now take brush, on which a little rottenstone and oil has been placed, and take off the burrs left from the file. Now do up edge of escape-wheel first with oilstone-slip, afterwards with burnisher. Now put escape-wheel and verge in plate, and see if the points of escape-wheel teeth come up nearly to, but without touching body of verge. If not, a little taken off front pivot of escape-wheel would effect this; but unless "A. B. C." has a lathe he will find this impracticable. Either the potance-wheel sunk a little, or a little taken off potance-face will do the same thing in an easier manner. Now see that "drop" is equal: that is, that the amount of drop on one pallet is equal to the amount of drop on the other. If not so, shift dovetail a little either one way or another, until the drop is equal. Now you can alter bankings by, in your case, moving the balance round a little to the side on which the train runs. If the verge is not too much worn, and the top and bottom verge-holes nicely "bottomed" out, and the other holes connected with escapement not too wide, and the verge

From W draw W a at right angles to E D and from V draw V b at right angles to E B.

Proof— $\because$ P R V X is parallelogram
$\therefore$ P R = X V
but— P R = K (const.)
$\therefore$ X V = K
again— $\because$ V L F B is parallelogram
$\therefore$ V b = L F
but— L F = H
$\therefore$ V b = H
and— $\because$ the $\underline{|\,\text{P R V}}$ of parallelogram P R V X is a right angle (const.)—Bk I. 34.
$\therefore$ $\underline{|\,\text{P X V}}$ is a right angle
$\therefore$ V X is a perpendicular to E D
and— V b may be shown in the same way at right angles to E B
$\therefore$ V is one of the required points

and in the same way it may be shown that the point W is another of the required points, and in the same way it may be shown that there are two of the required points in each of the four angles D E B, D E A, A E C, and C E B. $\because$ there are 8 of the required points (Q.E.F.)—ERNEST B. MARTIN.

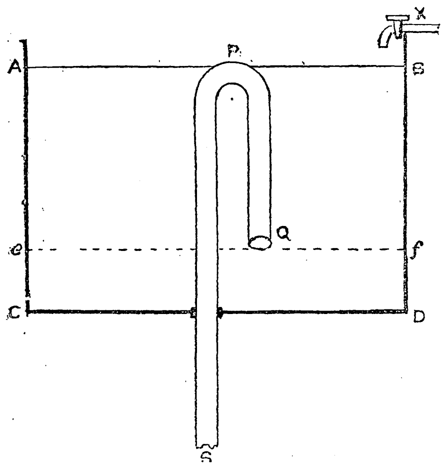
[60600.]—**Musical Intervals.**—Perhaps this querist will understand this matter if it is pointed out to him that if mid C is sounded by 264 vibrations, D will be given by 297, and E by 330. If, now, he divides 264 by 8, 297 by 9, and 330 by 10, he will see where the ratios come in. If further, he will remember that if 330 vibrations sound E, 352 will sound F, and 330 divided by 15 gives the same quotient as 352 divided by 16, he will have all the ratios of the tempered scale. I write the above as supplementary to what appears on p. 161; but it is not clear what the querist wishes to know. —N. E. CHILD.

[60601.]—**Battery for Electrotypy.**—Two or three Daniell cells of two-gallon capacity—better still, a good electro-plating dynamo machine.—G. E.

[60613.]—**Sanitary.**—If "Country Bricklayer" will communicate with us, we will give him full particulars respecting our flushing siphons. We shall be glad to have particulars as to how he has

fixed it, as if these siphons are not properly fixed, it sometimes causes them to fail in action.—DOULTON AND CO., Albert Embankment, S.E.

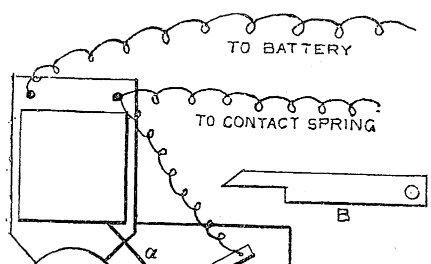
[60613.]—**Sanitary.**—There is a flushing siphon of the following description, but I am not sure



whether it is Doulton's:—A C B D is a tank of some sort, X a tap which is continually running, S P Q is a siphon, and S is the delivery. As soon as the water rises above the top of siphon P, the water will commence to flow out through S, till it reaches the level, *e f*, when it will stop. Of course, the flushing may be regulated by how fast the water is allowed to flow in by the tap. If the flushing is required to be frequent, the water must run in fast; if not, only slowly.—E. C. F.

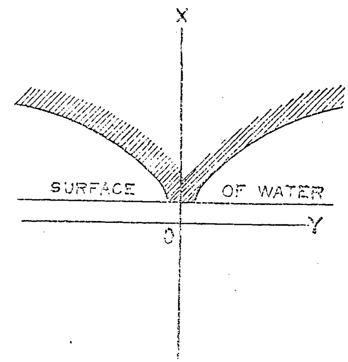
[60617.]—**Electric Light.**—I have looked up my reply, and I am sorry to say that I can only supplement my last week's note by giving you the size of the cell in question, which was a three-pint cell of the usual construction. If anything should come under my notice while experimenting I shall communicate at once with "Ours."—W. HOLDER, Newport, Mon.

[60620.]—**Electric Bells.**—The gauge of wire for the coils of a 6in. bell is No. 20 or 24. Doors and windows are connected to bells by means of contact springs, which are made for the purpose. Cheap and efficient ones can be purchased at any dealers; but if the querist wishes directions to make one himself, I shall be glad to give them. Annexed is a sketch of an arrangement by which



the bell will continue to ring, supposing the door or window has been opened and then closed. The hammer of the bell, *a*, has a piece of metal soldered to its centre, which projects outwards about ½in. A brass arm *b*, is loosely attached to a screw, from which a wire leads to the bell, as shown; *c* is a metal pin, from which a wire leads to the battery. The loose arm, of course, rests on the piece of metal projecting from the hammer. On the bell being rung the arm falls on *c*, and completes a new circuit, thus ringing the bell till *b* is lifted up. The shape of the arm is shown at B, the whole arrangement being mounted on a small board E.—BOBADIL.

[60631.]—**Hydrostatics.**—The accompanying sketch shows the shape of a body which will fulfil the conditions given by "Torbay,"—viz., that when gradually pushed below the surface of water, the submerged portion will always vary as the square of the depth. The exact curve may be calculated by the integral calculus thus: Let O be the origin of co-ordinates, X and Y the axes; suppose the two curves to be produced so as to meet at O, and let S = length of one of the curves, measuring such length to correspond with a length x measured along O X. Then, by the conditions of the problem, $x^2 = 2s$. I am supposing that the ends of the floating body may be ignored for the present. Our object is to find a relation between the co-ordinates



x and y, in order to describe the curves. Referring to Todhunter's "Int. Calculus," p. 104, our given function of x or ϕx is $\frac{x^2}{2}$, which $= s$; and $\phi^1 x = \frac{ds}{dx}$ will therefore be x. Therefore (as shown by Todhunter) $y = \int \sqrt{x^2 - 1} \, . \, dx$. This expression, when integrated, becomes—

$$\tfrac{1}{2}\left\{x\sqrt{x^2-1} - \text{hyp. log}\,(x + \sqrt{x^2-1})\right\} + C = y,$$

where C is some constant which we proceed to find. It will be seen from the above that when $x = O$ the expression is impossible, as we have the square root of -1; when $x = 1$, the expression becomes O, so that the curve begins when $x = 1$. Now to find C, we have $\frac{x^2}{2} = s$, and we have seen that S has no value when x is less than 1, but when we make $x = 1, s = \frac{1}{2}$; therefore, when the expression for y is made to vanish by making $x = O$, we must make $C = \frac{1}{2}$, so that y, C, and S are the same, and the curves will therefore start from points at a distance ½ on each side of the point where $x = 1$. This is rather difficult to understand, but I think I am right. The flat bit thus formed between the two ends of the curves will, of course, form part of the submerged surface.—P.S.: I find an error in my reply to this query. It will not do to consider the floating body as of indefinite length; in fact it can only be of a length equal to unity, the areas of the vertical ends when added to that of the curves will thus be greater than the square of the depth; but by stating the conditions of the problem a little differently, the calculation will hold good, thus, "required the shape of a floating body whose submerged areas (omitting those which are vertical) shall be equal to the square of the depth, when the body is pressed down to various depths." However, a more satisfactory reply to the question will be found by taking an inverted cone: the area of the surface submerged for any depth x will be found to be π tan. A . sec. A x^2, A being angle between axis and sloping side. Now, if this is to equal x^2, π tan. A . sec. A must be equal to 1, from whence we find that A = 16° 55′ nearly.—M.I.C.E., Bath.

[60632.]—**Spiral Steel Springs for Electric Lighting.**—I don't know, but I think, if "P., London," makes a small trough or basin, and fills it with water, and dropping the spring in immediately, pours a full broad stream of water in till cold, the cooling will be sudden enough: but a great drawback is the passing from fire to water through the air; make the distance as short as possible. With the above simple apparatus two will do the work better than one—one to pour. The answers on p. 160 are, I think, beside the point.—M., York.

[60634.]—**Safety-lamps in Mines.**—I am very glad to see your columns open for the discussion of so important a subject as that of safety-lamps. Mr. Shippey's statement that he can explode any lamp but the Morgan when using Mr. Morgan's test is misleading, because at the Leigh meeting Mr. Morgan himself failed to explode the McKinless lamp, and this, in all fairness, ought to be stated. In my opinion the Morgan lamp is of too complicated a construction—i.e., there are too many parts—to allow of its coming into general use, and I hold that simplicity of construction is a most important consideration when dealing with safety-lamps. For unless this is the case there is great danger (where several hundred lamps are being dealt with) of some part being left out, and the safety of the lamp thus impaired. In the Morgan lamp an omission of this sort would not easily be detected. "Nemo" says that the McKinless is not a practicable lamp in the pit. Now I have for some time past been using it daily, as also have many miners under my charge, and both the men and myself are so pleased with it that it is being adopted for the miner's use throughout our collieries. The lamp is not more difficult to handle than any Mueseler that I have yet seen, and, indeed, will stand more canting and knocking about than most Mueselers. I have no interest whatever in the McKinless lamp; but from my knowledge of it, obtained not in the lecture-room, but down in the mine, I must give my vote in its favour. It cannot be exploded, even by Mr. Morgan. There is no gauze to perish (and I find that gauzes in bonneted lamps have only a short life). It is simple in construction, cannot be put together wrong, and is easily taken to pieces and cleaned. I believe it is a fact that the lamp tested by the commission was not the improved McKinless, which, like the improved Morgan, was sent in too late. Whilst allowing that safety-lamps should be able to withstand almost any test, still, I do not think the blowpipe arrangement of Mr. Morgan a condition at all likely to occur in working coal.—PRACTICAL.

[60634.]—**Safety-Lamps in Mines.**—To me the Leigh experiments are no awakening, for my own have during the last two years taught me things that it is well for my peace of mind I did not know when daily travelling the pits. I am afraid I cannot help Mr. Henry Palmer to very much information as to the structure of the apparatus used; but from descriptions by persons who were present, I judge it to be a blowpipe with a foot-bellows, and the gas-feed delivered under pressure. If Mr. Palmer will refer to the Transactions of the Manchester Geological Society for the early part of this year, in a paper by the undersigned, he will find described and illustrated an apparatus of something of the same kind; and also another and larger one in which I saw the Morgan lamp fired on Friday, Oct. 8, at the Weepsend Gas Works, Sheffield, in about a minute. It fired again on Oct. 11 with a less explosive mixture in 2 minutes 38 seconds. On the last occasion the experimenter was Mr. Arnold Lupton, M.Inst.C.E., &c., lecturer on coal mining at the Yorkshire College of Science, Leeds, a well-known mining engineer. It is somewhat surprising to me that no one present at the Leigh experiments (*for there were dissenters*) seemed to see that the tests were unequal—that with a small jet of gas Mr. Morgan's lamp has a great advantage over any lamp, in testing which the jet can be directly impinged upon the wire gauze through the holes *in or at the base of* the single bonnet or cover. In Mr. Morgan's new lamp the holes in the outer bonnet or shield are in no case opposite the slots in the inner one, so that a jet driven through one hole or one group of holes in the outer shield strikes the inner one in a solid place, and is dispersed and deflected over a large area, and the velocity at which it enters gauze is diminished in the same ratio as the area of such entry increases. Now, put this lamp in a large volume of inflammable gas moving at great velocity, then the whole of the holes (or at least, those on the windward side of the lamp) are filled to their utmost capacity, and it fires readily with the most explosive mixture—even at a comparatively low velocity gas burns within the gauzes. The Morgan lamp has very considerable staying power, and I should say is quite safe at the highest *normal* speed of the ventilating currents of a colliery, the four gauzes giving it great power to condense heat. Some persons inquired at the Leigh meeting whether the lamps fired—particularly the Mueseler—were of the pattern giving the greatest amount of safety, or substantially to that effect; but the answer was not definite. If there are any of our fellow-readers who were present at the meeting, we shall be glad to hear further details. It is no part of my intention to controvert the statement put forth, that the four lamps specially commended by the Royal Commission on mine accidents were fired on this occasion. I know they can be fired—some of them very easily. The Gray and the Marsaut have been repeatedly, and Evan Thomas occasionally fired in velocities of 52ft. a second and under at Aldwarke Main Colliery by Mr. C. E. Rhodes, a gentleman whose experiments and research have contributed more to accurate knowledge of safety-lamps than those of any other individual living or dead. A Lancashire colliery owner, who is also a mining engineer of eminence, offered to light the gas in his office with a Marsaut safety-lamp in the presence of the writer about ten days ago. I saw another colliery man actually light the gas with a so-called safety-lamp of another inventor—not one of the four lamps commended, but a lamp in use in mines more fiery than the average of those with locked lamps. Now, going a little beyond the tests at Leigh. It is reported in the *Bolton Journal* that Mr. Morgan stated that a certain offer of £500 still held good. I do not quite understand whether the offer was in the shape of a premium for the best lamp—something like that lately held out by Mr. Ellis Lever—or whether it was the offer of such sum as a wager—the Morgan lamp against all comers. I rather judged the offer to be of the nature of the latter. On principle I do not bet,

but I will engage to produce a safety-lamp that shall give fully as large a light as Mr. Morgan's, and that shall be self-extinguishing in the most explosive mixture of gas and air, moving at a velocity and tested under the same condition that fires Mr. Morgan's lamp. The tests to be public, and the party failing to make good his claim to superiority to pay the expenses; or as each person's opinion is the result of honest conviction, let each pay one-half. The experiments to be conducted by responsible mining engineers and scientists.—W. CLIFFORD.

[60639.]—**Balloons.**—"First catch your gas" in a bladder, with a stopcock and nozzle fitted to it. Having done this, attach the balloon to the nozzle, and squeeze the bladder, which will naturally drive out the gas, whatever the pressure of indiarubber may be.—R. A. R. BENNETT.

[60639.]—**Balloons.**—Make a pump of 1in. and ½in. rubber hose, as illustrated in "E. M." of last week. Connect one end to main and the other to balloons, and work away with the foot as described. This is a very good substitute for an ordinary pump.—T. C., Bristol.

[60639.]—**Balloons.**—I do not know what may be the easiest way, but paper balloons can be filled by putting the gaspipe to them at the bottom, and leaving a small opening in the top—say, a piece of quill or tobacco pipe—through which the rising coal gas may expel the air. When the gas rises through this top opening strongly enough to light up and burn, the balloon is full. Indiarubber ones require an air-pump.—E. CONRY.

[60640.]—**Heating Apparatus.**—Carry up a vertical steam-pipe, and take branches off for each room; lay the pipes so as to drain back into the vertical pipe, to return the condensed water to boiler.—T. C., Bristol.

[60640.] — **Heating Apparatus.** — This condensation of water in the pipes is one of the greatest troubles of the hot-air engineer. The pipes are usually laid as straight as possible; but where bends inevitably occur, a tap (steam-tap) should be provided to drain off the water before putting the steam through. As soon as the pure steam begins to blow out the tap is closed, if it has not been done before.—E. CONRY.

[60641.]—**Horse-Power.**—Assuming the cut-off to be at ⅝in. the stroke, the effective pressure will be, say, 48lb.; area of cylinders combined = 1,021·4in. You do not give number of strokes per minute, so $\frac{48 \times 1{,}021{\cdot}4 \times 7 \times \text{number of strokes}}{33{,}000}$ = H.P. of engines.—T. C., Bristol.

[60642.]—**Dynamo Building.**—TO S. BOTTONE, &C.—Try to run the armature the other way—viz., against the brushes. Have you magnetised the field in any way by coupling up to a battery, or other dynamo, for a few minutes? If not, do so.—S. BOTTONE.

[60642.]—**Dynamo Building.**—Will you give the exact connections of your machine, and say whether you have tested the circuits right through with a galvanometer, to see if they are all right and a good connection everywhere? If the machine is made all right according to "Xero's" instructions, and you find the circuits are all right and the connections, where movable, are all screwed down tightly, yet when running you cannot get any spark on, take a short bit of fine wire, and touch it on both brushes, so as to short-circuit the armature for an instant; this often makes an obstinate dynamo start when nothing else will. If this will not make the machine "build up," get one or two large cells of a primary battery or some small ones coupled in parallel, or an accumulator or two, and put their current round the field magnets for an hour, as the iron of these may have got demagnetised, or perhaps has not in it (on account of quality) enough residual magnetism to make the machine start.—E. CONRY.

[60643.]—**Electrical.**—The resistance of coils and armature in a series-wound machine should be as follows:—Armature, 1; field magnet coils, ¾ to 1; outer circuit, 2. Shunt-wound machines:—Armature, 1; field magnets coils, 400; outer circuit, 20. The compound-wound machine will vary in its resistances, according to whether it is built to give constant current and varying E.M.F., or constant E.M.F. and varying current.—S. BOTTONE.

[60643.]—**Electrical.**—The field-magnets of a series-wound dynamo should be of slightly less resistance than that of the armature; the proportions should be about $\frac{9}{10}$ to 1. In the shunt wound the relative resistances vary greatly according to the shape, winding, and other matters; but, generally speaking, the proportionate resistance of the field-magnets should be rather less than the above, say, $\frac{16}{20}$ to 1. The above applies only to ring armatures connected in series. Compound winding generally does not make much difference in the proportions, I believe, but what difference it does make is rather in the direction of increasing the F.M. power by more ampère turns, or less resistance of F.M. circuit, according to the nature of the machine.—E. CONRY.

[60643.] — **Electrical.** — *Series Machines.*—The resistance of the field-magnets should be a little less than that of the armature. *Shunt.*—To obtain 90 per cent. efficiency, the resistance of the shunt must be at least 364 times that of the armature. *Compound.*—For constant potential, when only one lamp is running the shunt wire on the field alone maintains the magnetism, practically speaking, and therefore the resistance of the shunt must be the same as in a shunt machine. The turns of series wire serve to counteract the demagnetising influence of the armature, and the number of them is in reality always determined experimentally. You can find the formulæ in S. P. Thompson's "Dynamo Electricity." Bear in mind that the magnetic circuit is just as important as the electric circuit of the machines, and that you will not make a good dynamo merely by putting the proper length of wire on the cores. You would find it instructive to compare the figures given in the catalogues of the various makers. Other considerations than high efficiency influence the results.—BARKER AND CO.

[60644.]—**Heating Surface.**—Surface of crown of box = 8 × 8 × ·7854 = 50·26in., and of vertical surface = 8 × $3\frac{1}{7}$ × 10 = 251·2; the total will therefore be 301·46in., or about $2\frac{1}{7}$ square feet of surface.—T. C., Bristol.

[60644.] — **Heating Surface.** — The firebox being cylindrical, area would be—

$$2\left(\frac{\pi d^2}{4}\right) + (\pi \times 8) \times 10 \text{ sq. in.}$$

i.e. $$2\left(\frac{3{\cdot}1416 \,.\, 8^2}{4}\right) + (3{\cdot}1416 \times 8)\,10$$

or $$2\,({\cdot}7854 \times 64) + 31{\cdot}416 \times 8 = 125{\cdot}654 \text{ sq. in.}$$

The area of any circle is 3·1416 (or as it is called for convenience π, pronounced "pie") multiplied by the diameter, and the product divided by 4. The circumference of any circle is π × diameter, and therefore the area of any cylinder, excluding top and bottom, which we have already reckoned for, is the height × π × diam.—E. CONRY.

[60646.]—**Cracked Gongs.**—They are practically useless now. Better sell them as old metal. They may be melted and recast.—W. HOLDER, Newport, Mon.

[60646.]—**Cracked Gongs.**—Cut along the cracks with a metal saw—a fret saw will do—until the sound metal is reached. The object is to separate the edges of the crack, and prevent them rubbing against one another.—SAML. RAY.

[60646.]—**Cracked Gongs.**—If the cracks are at the edge and not very long, drill a small hole at the bottom of the crack and then saw down the crack to the hole; in other words, remove the edges, so that they do not touch when they vibrate.—T. C., Bristol.

[60646.] — **Cracked Gongs.** — They can be mended by running melted metal into the crack, in the same way that Big Ben, the Westminster bell, was mended; but I think you would find it more trouble and expense than the things are worth.—E. CONRY.

[60647.]—**Music Stand.**—If querist will look at a common article of furniture to be found in most houses and furniture shops, called a what-not, he will see at a glance how the pillars of his music stand should be placed.—DOCTOR MEDICINÆ.

[60647.]—**Music Stand.**—I have seen camp furniture put together by making one leg, the upper, for convenience, with a strong screw in it, which passes through a small hole in the horizontal wooden shelf and screws into a screw-hole bored and threaded for it, in the top of the corresponding under pillar, so that the shelves are nipped between the top of one pillar and the bottom of the next, when the two are screwed up tight.—E. CONRY.

[60648.]—**Transparency.**—Put a negative into a printing frame (you can cut them the right size with a diamond), and a plate behind it—film to film. Expose them to a lighted candle flame, about half a foot distance, for about 20 secs. If it is a good, dense negative, the best developer is said to be ferrous oxalate; but, if you can't manage that, sodic sulphite gives first-rate results. Thick negatives make the best transparencies—i.e., those with plenty of contrast. A sodic-sulphite developed negative gives a better transparency than a pyro-ammonia developed one. Will give you more information if you like to write to me.—R. A. R. BENNETT, Walton Manor Lodge, Oxford.

[60648.]—**Transparency.**—TO S. BOTTONE.—If W. W. Railey will make up some fresh ferrous oxalate, by mixing fresh iron sulphate solution with fresh potash oxalate solution, both saturate, in the proportion of one of the former to three parts of the latter, I have no doubt but that he will succeed. To the developing solution he must add bromide of potassium, in the proportion of five or six grains to each ounce. By so doing, the development will be very slow, but the shadows will be quite clear, and the colour excellent. Contact printing must be adopted, but it must be done, not by daylight, but by the light of a single burner, either paraffin or gas; and the greatest care must be taken that no light fall on the picture or plate at any time except that of exposure.—S. BOTTONE.

[60649.]—**Low-resistance Lamp.**—TO MR. BOTTONE.—Yes, a 20c.p. lamp of the Bernstein type would suit your dynamo very well.—S. BOTTONE.

[60650.]—**Geometry.**—For the same reason that the bisectors of the interior angles meet in a point, so do the bisectors of the exterior angles. Bisect all possible exterior angles, and produce the lines and you will see "why."—M., York.

[60651.]—**Electric Signals in a Mine.**—This is a query which can only be answered in a practical way. You had better employ a respectable firm who will undertake the work and guarantee it. If your wire eats away, why don't you speak of it to the people you obtained it from. For the signals you want, the best materials and workmanship should be used. A single well-insulated wire should be run to each of the levels you want to communicate with, and an earth return used. This will enable you to communicate singly. If a single wire is used each bell will ring at one time, and different signals must be used to denote the level you want to communicate with. Single-stroke gongs are generally used, but it does not signify. The price is best obtained by consulting a list. The push button would make no difference to the barometer.—C. D. R.

[60651.]—**Electric Signals in a Mine.**—Your letter is interesting, and I feel sure that many readers of "Ours," in common with myself, would like to hear further particulars, if you would furnish them, as to the description of guttapercha, wire, the gauge of the wire, and thickness of the covering, and whether the wire was tinned or not; if not tinned, it should have been, as the tin covering is an immense preventative of oxidation. It seems that the gases of the mine penetrated through cracks in the guttapercha covering, and attacked the copper, probably aided in their work by acids of some sort in the guttapercha itself. This latter always oxidises the surface of untinned copper wire. I should think the best wire for your purpose would be tinned indiarubber, and double-cotton covered and paraffined; it is a wire made specially for bellwork, and both the inner covering of soft, brown indiarubber and the paraffin are first-rate materials for resisting the action of corrosive substances. The insulation is also very good for resisting scraping, cutting edges, or other unintentional method of making contacts. It is not easy to see from your words whether you run the wire in casing or otherwise. If in casing, I should say No. 20, as above, would do; but if the wire is run on insulators, or in any other way exposed to the open air, I should recommend No. 18 at least, and as thick a covering of indiarubber and paraffined cotton as the manufacturers have. Look up some names in the directory, and write for samples. You would want a separate wire for each level, but one return would do for the lot. Either trembling bells or single-stroke will do, and there is not much difference in the price. The "push" would not have any effect on a barometer and thermometer. I should think an ordinary vibrating indicator would be as good as anything. I should think a latch indicator would not be safe, nor yet an electric motion and reversal indicator, because the working of both kinds depends on a nice adjustment of small moving metal parts, which might get out of order with the gases of the mine, and you could then arrange a system of signals by strokes of the bell. If you want more than this, I should advise telephones, or simple telegraph instruments like the letter telegraph (magnets) instrument in use in the P.O. service. I gave in last number a diagram of telegraph connections—if that will be useful to you.—E. CONRY.

[60652.]—**Small Dynamo.**—The dimensions given are not very good. I should advise you to have a laminated Siemens armature, about 8in. long by 2½in. diameter. Let this be wound with about 1lb. No. 20 or 18. The commutators to be in two sections only. Each limb of the F.M. should be cast in one piece with the pole-piece and lug which form the yoke, of this shape ┌ nearly, the lower extremity having the semicircular pole-piece cast on it. The distance between the pole-pieces should be only just enough to let the armature rotate between them. The height of F.M.'s about 4in. from pole-piece to yoke. Wire on F.M.'s about 7lb. No. 16.—S. BOTTONE.

[60653.]—**Rust Joints for Socket-pipes.**—I do not know if it is wise to use a rust joint for so high a pressure as 100lb. on the square inch; but I have used it for steam up to 50lb. with every satisfaction. For the method, put the end of your pipe into the socket, lap two or three turns of old rope, or thick, soft cord, round the pipe, and drive this

down to the end of the socket with a wooden wedge, or something similar; then with a wooden or iron wedge, or any conveniently shaped tool, drive into the socket all round, as tightly as you can, iron filings, or small borings and turnings (these are best), thoroughly wetted with weak solution of sal-ammoniac and water, not much stronger to the taste than sea water. The great mistake of most people in making rust joints is making the solution too strong, so that the iron filings, instead of being rusted, are entirely rotted away by rust. When the socket is almost as full as it will hold, jam in a turn of old rope, so as just to keep the filings in till they are set. I do not see any reason why rust-joints should not be used for even 100lb. pressure. —E. CONRY.

[60653.]—**Rust Joints.**— Iron borings, mixed with 1 per cent. by weight of sal-ammoniac, and ½ per cent. of flowers of sulphur. Moisten and caulk in tight with suitable tool, and let it rest two or three days. But 100lb. pressure is rather high for rust joints.—T. C., Bristol.

[60656.]—**German Ph.D.**—At what university? At that of Weissnichtwo you pay your fees, and pay a Grub-street hack, called there a "Professor of Allerlei-Wissenschaft," to write you a thesis on certain recondite phenomena of microcosmic agglutinations.—NEPHESH.

[60657.]—**Battery for Lathe Motor.**—You can fit up a motor yourself if you have a knowledge of tools and lathe. Motors and their construction have been described several times in these columns. To drive a lathe you will require a very large battery, either bichromate or Bunsen. It will mean a large expense and a great deal of trouble.—C. D. R.

[60657.]—**Battery for Lathe Motor.**—Three or four large double-fluid bichromate or chromic acid cells would do you probably as well as anything. There have been several descriptions in recent numbers. I described a small motor in "E. M.," Oct. 1st, which I think would do for you; but I should advise making it larger, say double the dimensions given, everywhere, and put two more layers on field-magnets, and as much more on the armature of the same wire already given for it, as it will hold. Keep the faces of the armature as close to the pole-pieces of the magnets as you possibly can short of touching. You would, of course, have to start the lathe or grindstone by hand.—E. CONRY.

[60658.]—**Indiarubber Solution.**—If too thick, put in naphtha. If the use you put solution to is applying it to the worn parts of stocking to make waterproof, two or three coats will do that; but the solution will not stand wear like vulcanised rubber, of which the stocking is made.—R. N.

[60660.]—**Electric Light.**—TO MR. BOTTONE AND OTHERS.—One 2½c.p. lamp would do, if placed close; but a 5c.p. would be much more satisfactory. If the lamps are properly arranged so as to make up the same resistance as the eight 20's, you can run sixty-eight 2½'s, or thirty-four 5's. About 1½ H.P. will drive the dynamo easily. Lamps cost about £3 per dozen. I could make such a dynamo for about £8. A laminated Pacinotti would suit best.—S. BOTTONE.

[60660.]—**Electric Light.**—One 2½ c.p. lamp would not give anything like enough light. One 10c.p. to each machine would be nearer the mark. I am sure you could not do with less than this for such small particular work. If the res. of the 2½c.p. lamps will allow of five of them in series making up about the res. of one 20c.p., then the same dynamo would do; but if the dynamo is a shunt-wound machine you can make it light lamps of very widely differing resistances by adjustment of speed and resistances in the machine. You do not say what the voltage of your lamps is; but if about 40 volts, then the eight would take together about 450 watts in the dynamo, or about 1 H.P. in your engine driving-wheel. The cost of the lamps depends on the makers. At sales you can often get them for 1s. 6d., 2s. a piece, but the best would be about 50s. a dozen. I should think the Patterson and Cooper "Phœnix" to give about 60 volts and 15 20 amps. would do for you as well as any, and as cheap; or you might try Mather and Platt's "Manchester" machine, which is a good one.—E. CONRY.

[60661.]—**Electro-Motor.**—See reply to No. 60657. You can have no idea as to the cost and trouble of a motor to give out two or three horse-power. It is not practicable to use primary batteries; the expense is enormous. Don't bother about it—you had much better put a steam-engine in. The only near approach to practicability would be to use secondary cells, and to charge these you would require a steam-engine and dynamo.—C. D. R.

[60661.]—**Electro-Motors.**—If you really require your motor to develop 2 or 3 horse-power you have a difficult task before you, and it would be advisable to commence on a smaller scale—say, 1 man-power. Trouvé, of Paris, has been very successful in propelling boats by electricity, with bichromate batteries as the source of power. You cannot do better than follow his general arrangements, particularly those relating to the battery. His motor is of the Siemens H pattern, with speed-reducing gear attached; but this type is out of date now. If you like to communicate with us direct, we can supply you with working drawings of a four-pole motor. (See our advertisement.)—BARKER AND CO.

[60662.]—**Solution of High Specific Gravity.** —The liquid used was "Sonstadt's solution," which was described in Vol. XXVI. p. 327, in a paper by A. H. Church, M.A., who gave its sp. gr. as 3·01. To prepare it, "Mercuric iodide and potassium iodide are alternately dissolved in a saturated solution of the latter salt until no more of either compound is taken up. The resulting liquid may be diluted at will with water." I did not measure the sp. gr. of what I made for finding the diamond, but flint glass floated on it.—J. BROWN, Belfast.

[60663.]—**G.E.R. Locos.**—The reply to this query would require a lot of space. If G. Head will write to me, I shall be happy to give him the information.—E. INNES, 66, Finsbury Park-road, London.

[60666.]—**Card and Wood-Cutting.**—Henry Mills, of Bodega-passage, Birmingham, is well known to printers as the maker of knives for cutting fancy shapes in paper and cardboard, but I do not know whether they could be used for wood.—A PRINTER.

[60667.]—**Magneto-Electric Call Bell.**— There are several forms. The best consists in a small magneto-dynamo, which generates current on rotating a handle. This current is led to the electro-magnet of the bell, the same as if it were from a battery. The magneto is almost the same as a medical magneto, except that a commutator is put on the armature spindle of such a kind as to send the currents all in the same direction.—S. BOTTONE.

[60669.]—**Gut Driving Bands.** — Taper the ends so as just to enter. Grease the end, and then screw into the hook. Cut off any that comes through, and screw up as far as it will go without cutting the gut. I have always found above to answer. The gut should not unravel if it does not rub anywhere.—T. C., Bristol.

[60669.]—**Gut Driving Bands.**—Hooks and eyes are secured to gut bands by simply screwing them on to the ends of the gut; both the hooks and eyes have a screw thread purposely provided for this. They should, of course, approximate the size of the gut. If they are too small, just file the gut, taper a little, and then screw them on; properly made gut does not unravel—if yours does so, get some better quality.—C. D. R.

[60670.—**Electric Tram.**—TO MR. BOTTONE. —Cores C-shaped, 3in. long, 1in. wide, ¼in. thick, wound with four layers No. 22 s. c. wire, armature Gramme pattern, 1in. internal diameter, also wound with No. 22.—S. BOTTONE.

[60672.]—**Battery.**—You have tried the best known batteries for this purpose. The only thing you can do now is to get a dynamo.—C. D. R.

[60672.]—**Battery.** — Any double-fluid bichromate, such as the Fuller's, will answer perfectly. But all batteries are expensive and messy. Why not have a small dynamo?—S. BOTTONE.

[60672.]—**Battery.**—According to the accounts given in the last volume, you cannot have a more serviceable battery than that illustrated on p. 561, No. 1,117; but I suppose you have looked up back numbers before sending such a query.—F. I. C.

[60672.]—**Battery.**—The working cost of Daniell cells is about half that of Bunsens, and though both are troublesome, you would find the Daniell least so. There is, however, a modification of the Leclanché cell now being introduced for lighting purposes, which has an internal resistance of only about ·03. The patentee is Octavius March, care of—C. D. BARKER AND CO.

[60673.]—**Mechanics.**— If the joists are 1¼in. wide they would be strong enough; but you had better use nothing under 1½in., and brace them at that.—T. C., Bristol.

[60673.]—**Mechanics.**—The breaking weights of beams of rectangular section increase as the squares of the depths and as the breadths increase, and decrease as the lengths increase. Therefore the breadth must increase as the length and weight increase, and decrease as the square of the depth increases. Then, the length, depth, and weight being given, the required breadth will be $\frac{8064 \times 144 \times 2^2 \times 2}{2000 \times 50 \times 10^2} = \cdot 93\text{in.}$ Where 8064 is six times the number of pounds in 12cwt., 144 is 12ft. in inches, and two is the depth and breadth of the experimental beam; 2,000 is twice its centre breaking weight in pounds, 50 its length in inches, and 10 the depth of the given beam in inches; 1,000lb. in the centre of 4ft. 2in. × 2in. × 2in. is rather a high breaking weight; 750lb. is nearer the weight for timber taken as it comes in the market.—J. S. C.

[60675.]—**Fire.**—Much depends on the coal you use. I have found that known as Ilkeston Brights keep in through the night in an open grate with little or no poking. This coal burns away to the last mite, leaving no cinder, but only ashes.—W. A. S.

[60675.]—**Fire.** — A new invention called the Edford briquettes would probably be of use to "E.G." and others wishing to keep a fire burning all night without attendance. Two of the briquettes broken into a few pieces will keep burning for 24 hours without any attention, and for this reason they are specially useful in the sick-room. I shall be happy to inform any reader where they may be obtained if he advertises his address.—S. E. MCNAIR.

[60675.]—**Fire.**—This query should really state whether the "fire" is a furnace, or merely a house fire, and even then whether kitchen or parlour. Anyway, sufficient coal must be put on, and that kind known as Derby Bright is better than Wallsend, as it is termed, which will certainly go out unless the poker is applied. What is "throughout the night," though? How many hours? If from, say, 12 p.m. to 6 a.m., there is little difficulty if the grate is carefully packed with small pieces, and the top is covered slightly with dust.—SAML. RAY.

[60675.] —**Fire—Keeping Alight.**—"E. G." does not say what kind of grate or fireplace he has; but, presuming it to be an ordinary one, he might try the following. Cut a piece of sheet-iron to cover the bottom of grate. Fill up to level of top bar with pieces of coal the size of Macadam stones (largest at bottom); on this place paper and wood, with some cinders and a few small pieces of coal. Light, and let it burn downwards. If the grate is large enough to hold a fair supply of coal, you will get a glowing fire that will keep in a long while. I have also seen a sort of cloth made of asbestos, which was placed on the top of the coals to keep the fire in. Both plans act by checking the draught.—D. G.

[60678.]—**Varnish to Harden Paper.**—Soak in linseed oil, and when dry, coat with copal. Probably wood has been found cheaper and more trustworthy than papier mâché.—SAML. RAY.

[60678.]—**Varnish to Harden Paper.**—I think querist will find what he requires in Willesden paper, made by a company at Willesden, London, which can be had from the thickness of writing paper to ⅛in., and as hard as a board.—DOCTOR MEDICINÆ.

[60678.]—**Varnish to Harden Paper.**—Let "Photo" dissolve orange shellac in spirits of wine till thick as treacle. If two coats are given, and two pieces are put together when they get in a nice sticky condition, they make a good slide. They are put under pressure between two flat surfaces to dry straight.—LIGHT-WEIGHT.

[60679.]—**Ink for Window Tickets.**—Grind up any of the desired pigments with gum water, and use with a "pencil"—that is, an artist's paint-brush. If weather hot and dry, add a little glycerine; but you need not if it is like what it is while I write this—damp and miserable.—SAML. RAY.

[60680.]—**Field Magnets.**—This querist reminds me of Charles II. and the fishes. The armatures in the best machines do actually revolve in the field of the greatest density; it is only in defective machines that anything else takes place. Has not this querist quite misunderstood the winding of the Elwell-Parker dynamo? If "Ampèremeter" will turn to the ENGLISH MECHANIC, Vol. XLII., page 85, he will find an illustration and explanation of the mode of winding a drum armature; and if he does not understand this, I shall be happy to lend him a small model.—S. BOTTONE.

[60680.]—**Field Magnets.**—The circuits of the magnetic lines of force are completed through the paths of least resistance. The iron cores of the armature in a well-constructed dynamo nearly unite the two poles, the layers of wire and the clearance space being the only part of the magnetic circuit that is not iron. The lines of force that do not take this path are wasted, but they are few in comparison with those that pass through the armature. You must be mistaken about the Elwell-Parker machines. The poles are wound the same as in other machines. The diagrams for winding drum armatures certainly require careful study, but they are the best means of explanation short of a demonstration.—BARKER AND CO.

[60682.]—**Leclanche Batteries.**—It is quite possible to charge with too strong a solution. The best under all circumstances is a half-saturated one of salammoniac. Are you sure the solution contained nothing else but this salt? What sort of zinc have

you used? If this is impure, and of bad quality, it will cause a great deal of trouble. Empty your cells and recharge as above, and if the zincs are bad, exchange them for good.—C. D. R.

[60683.]—**Electric Bell Indicator.**—From the description given, this is a polarised needle movement, and, I should say, of very common make. Try and ascertain if the indicator movements will act without the bell; if so, you must increase your battery power until both bell and indicator act together. I presume that the indicator is coupled up correctly. It should be wire from carbon to bell-pull to terminal marked carbon on indicator. The rest of the terminals will, of course, be connected to the different push wires, and form these to the zinc.—C. D. R.

[60687.]—**Screw-Cutting.** — You do not give the pitch of your leading screw. The screw is $\frac{89}{18}$ of an inch, and you will, therefore, require a special wheel of 89 teeth, although it is possible to do it with a 90 wheel; but the "game is not worth the candle." See Holtzapffel for the method.—T. C., Bristol.

[60687.]—**Screw-Cutting.**—To cut 18 threads in 22¼in., use a driver having same number of teeth as lead-screw has threads in 22¼in. (or 44½in. as the case may be)—i.e., 89 and 18 would naturally be your screw wheel, but 89 and 18 are not workable. If leading screw is ¼in. pitch, use screw 36, stud $\left\{\begin{matrix}\text{driver } 89\\ \text{driven } 20\end{matrix}\right\}$, mandrel 40, driving the 20 by means of two idle stud wheels of suitable size to the lathe.—H. O., Glasgow.

[60687.]—**Screw-Cutting.**—You omit to state the pitch of your leading screw, but I assume four threads to the inch. If there are two threads, you must halve one of the drivers, or double one of the driven. You want 18 threads in 22¼in., and the leading screw having 4 per inch contains 22¼ × 4 = 89 threads in 22¼in. Hence the ratio is $\frac{89}{18} = 4{\cdot}944$, which are the ratios of the screws, and therefore of the drivers and driven wheels which are to be sought. To cut these absolutely correct you must have the special wheels 89 and 18, or multiples of the same; but you can cut with sufficient approximation for most purposes by taking instead $\frac{90}{18}$ and deducing suitable wheels; $\frac{90}{18}$ gives a ratio of 5, but by conveniently reducing by 1-18th we get $\frac{84}{17}$, whose ratio is 4·941, which is very near the mark. Deducing the wheels $\frac{7 \times 12}{17 \times 1} = \frac{70 \times 120}{170 \times 10}$ substituting $\frac{70 \times 120}{85 \times 20} = 4{\cdot}941$ ratio, and 70 × 120 are drivers, and 85 by 20 driven.—J. H.

[60687.]—**Screw-Cutting.**—The following is offered as a variation of the ordinary rules for finding change wheels. If worked out step by step, it gives an analysis of the possible changes that few others give. Set the number of threads to inch required on the mandrel, or set down the number of inches to a thread, as the number of teeth to be put on the screw, multiplying this by the number of threads to inch of leading screw. Put intermediate wheels as having an equal number of teeth for trial. Multiply or divide any two numbers which gear into one another by any suitable number until the wheels are of such numbers as are usually supplied. Thus: required, 18 threads in 22¼ inches; say, leading screw 4 threads to inch. Then 18 on mandrel, 22¼ × 4 = 89 on screw. Put intermediates at 20 each, then diagram:—

Mandrel 18 gears, 20
||
20 gears 89 screw.

Multiply the first pair of gears by 5; then mandrel 90 gears, 100
||
20 gears 89 screw.

Unfortunately, no available wheel number will go as factors into 89 (prime number). Had 18 turns in 22½in. been required, then 90 — 100
||
20 — 90;

but as 90 here occurs twice, halve the first pair; thus 49 — 50
||
20 — 90.

Should leading screw be one or two threads to inch, multiply one of the drivers (or divide one of the driven) by 4 or 2 respectively; thus, last gear, 80 — 90, or 40 — 90.—Nephesh.

[60688.]—**Nickel Silver.**—You would probably get the information from Cooper Brothers, Don Plate Works, Sheffield, or from other manufacturers of nickel silver. The metal is rolled into sheets; but cannot say as to wire.—Nephesh.

[60689.]—**Silvering Glass.**—It is generally the usual Rochelle salt process, which has been described over and over again. I see by the last index there are several references to the subject, and there is certainly no "patent" in it. Called patent merely to distinguish it from the old mercury process.—Nun. Dor.

[60690.]—**Wood Carving.**—Illustrations of the tools are given in such lists as that issued by Melhuish, of Fetter-lane, E.C. A "few hints" would be no use; better procure a handbook of the art and—practise. But if you want to make a living at it, rest assured there is no room except for the artist workman.—Scorper.

[60691.]—**Wood Naphtha.**—To one gallon add 3½lb. dried and hot pearlashes, agitation repeated every hour for a day; decant. If not free from water as you would like, repeat with fresh ashes.—R. N.

[60691.]—**Wood Naphtha.**—Let this stand for some time in a tall vessel, and the spirit will separate and rise to the top, whence it may be siphoned off. Or it may be distilled over.—T. C., Bristol.

[60695.]—**Model Marine Boiler.**—Solder or braze these in. Have the tubes as large as you can get them in, and look in almost any optician's window at one of these model boilers; that will be better than a sketch.—T. C., Bristol.

[60697.]—**Electric Lighting.**—If "Amateur" looks at the craters of his carbons he will instantly be able to say whether the current through the lamps is or is not reversed. The lamps are probably burning with the positive pole at the top, but from bad regulation burn the carbons irregularly. By making a slight difference in the regulation a lamp that burns the upper carbon too fast can be made to burn the lower one too fast. See that the proper current passes through each lamp, and that it burns steadily with an arc of the normal length, and your difficulties with the carbons will disappear.—Barker and Co.

[60698.]—**Lathe Speed Pulley.**—Your question does not give size of wheel and distance of centres. If the grooves in wheel have a difference of 1⅝in., I believe you will be suited. Say 21in. and 19⅜in.—T. C., Bristol.

[60700.]—**To Draughtsmen.**—Step it out with dividers is by far the most workmanlike and quickest way.—Nephesh.

[60703.]—**Galvanism.**—As I have been suffering from a complaint strangely like "R. J. T.'s" in symptoms, treatment, and results, I look forward with much interest to Mr. Bottone's reply. In the mean time, may I be allowed to state, for "R. J. T.'s" information, that I recently heard of a homœopathic remedy, "Cimicifuga," and have derived more benefit from its use than from all the other remedies put together?—C. M. C.

[60703.]—**Galvanism.**—To Mr. Bottone.—Although not a medical man, I think I may safely advise you to use the intermittent current from a magneto machine or medical coil. Place a good large copper plate on the back, in connection with one electrode, and pass a large spoon, connected to the other electrode, with a stroking motion along the affected ribs, side, and shoulder. It does not matter much which electrode is connected to the plate in this case.—S. Bottone.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

A French authority gives the following recipe for transparent cement:—The advantage claimed is the absence of the slightest yellow tinge, so that the addition of the cement is imperceptible, while it possesses an extreme degree of tenacity: Mix in a well-stoppered bottle 10 drachms of chloroform with 12½ drachms of non-vulcanised caoutchouc in small pieces. The solution is easily effected; when finished add 2½ drachms of mastic, and let the whole macerate from 8 to 10 days, but without heat. A perfectly white and very adhesive cement s thus produced.

QUERIES.

[60704.]—**β 63, and 178 Dolphin.** — Will Mr. Sadler kindly inform me of latest measurement of β 63, and 178 Dolphin. On the 6th Oct. I looked once more at these, and, to my delight, saw β 63 clean apart. I did not know the P. angle or distance, only that it was a small co. and difficult, as I had looked at it unsuccessfully scores of times with 8½, 10, and 12in. mirrors. I booked it at 350° P. angle, and found it in Gledhill's Burnham list as 6·11 mags., 340° 0·7″. I saw it well with a Browning E eyepiece, on 10in. of 12¼ Linscott mirror, my J Browning mirror being in town for new silvering. Then I looked at 178, and saw the small pair not separated, estimated angle at 45° or 225°, and it is nearly that in Gledhill. Air much better than usual, but would not bear 500 at stars low down. With 500 Cooke eyepiece, I saw very finely OΣ 371 Lyræ at 0·8″, and Σ 2491 extremely clearly on 10in. of 12¼; also 16 Vulpis at 0·7″ and 2 Vulpis with the E eyepiece and the triple 6968 Lyræ. Too quickly the wretched cirrus came from S.W., spoiling definition long before it was visible near the stars; then all over. I constantly see the star centre in Neb. 37 H IV. Draconis, mentioned by Mr. Knott in the "E.M.," and notice the disc-like appearance; but it shows best in very clear air, not hazy, as real stars often do.—Bramley.

[60705.]—**Dutch Language.**—I wish to study the Dutch language, but have difficulty in obtaining the necessary books. Could any correspondent inform me of any elementary course or work on the subject suitable for a beginner?—M. C. Z.

[60706.]—**American Medical Law.**—I shall be much obliged if some of our numerous correspondents will give me the particulars of what States the M.R.C.S. (E.) and L.R.C.P. (London) are qualifications for medical practice without other exams.? The names of the different licensing bodies, and in what States their qualifications are available? What their diplomas are, and the rough outline of their curriculum? If a man going over from England, having passed his primary exams. for the above-mentioned qualifications—e.g., materia medica, chemistry, anatomy, physiology, &c., with his full curriculum of lectures, &c., attended, would he be required to pass again in those subjects or to attend medicine and surgery lectures with hospital practice a second time, provided he went over with good credentials from the authorities here? Is there any opening for a man who is well up in the demonstration of histology and microscopical morbid anatomy with first-class credentials? Any information on above points will oblige—Microtome.

[60707.]—**Dynamo.** — To Mr. Bottone. — Many thanks for answer to query 60476. I join the two ends of wires on fields to brushes, and get very little current on outer circuit; but if I join the beginning ends of both limbs to one brush, and the finishing to the other, I then get a good current, and the dynamo drags heavily. Both limbs are wound right-hand, which I think should make N. and S. fields. Will you please put me right if I am wrong?—D. B. S.

[60708.]—**To Mr. Bottone.** — I am thinking of making a Wimshurst machine the same as you have described in the English Mechanic. As I have been given to understand that the steel spindle carrying the discs should be in one length so as to bring the neutralising rods in metallic connection with each other, do you think the machine would give as good results with the spindle in two parts as you recommend, thus insulating one neutralising rod from the other? Do you think very thin sheet brass about the thickness of common tin plate would do better for the sectors than tinfoil? I thought of sticking them to the discs with good tricycle cement. Do you think the bichromate paste you recommended some time ago would be better for attaching the discs to the bosses than tricycle cement? Would you kindly tell me of some simple way of testing the quality of the glass jars and discs? An early answer will greatly oblige—J. R.

[60709.] — **Electro-Metallurgy.** — I hear that several large firms of copper smelters and refiners in Swansea have adopted the dynamo system for the extraction of copper and zinc in a metallic condition from the ore; and that this plan is replacing the old one of smelting. I have been experimenting on both copper, iron, and zinc. I have succeeded with the copper, but not with zinc. My zinc ore contains a large percentage of Pb, Fe, Si, and a little Cu. I have used thin sheet-iron plates for anode and cathode. I have ground up my ore and then covered it with a dilute sol. of HCl, and then neutralised by caustic soda sol.; but I get no result. Why and in what direction have I failed? Any hints will be most acceptable.—A. B. H. Faudelle.

[60710.]—**German Universities.**—I am thinking of sending one of my sons to a German or Prussian University, and as I am quite ignorant of the "mode of procedure," I shall be glad of any information. Are there any books (in English) from which I could glean any information? Is it needful that the youth should know German before going? I have been told that it is not, and that he would "pick it up" very easily while there. My idea in sending him is to get a good scientific training and the Ph.D. deg. What is the probable cost?—A. B. H. Faudelle.

[60711.] — **Rendering Ground Glass Transparent.**—Can anyone help me in the following? I have two panels of ground glass in a door. Can I, by varnishing the "ground" side of the glass, render it transparent, or nearly so, previous to decorating the other side with imitation stained glass (glacier)? If so, what varnish should I use? Any hints from any of "ours" who have used the "glacier" process would also be very acceptable. The door is in a passage, so that neither side of the glass would be exposed to the weather.—D. G.

[60712.]—**M.R. Engines.**—Could anyone tell me the dates of M.R. engines 1326, 1347, 1432, 1451? Also, how many single engines has the M.R.?—F. A. Holmes.

[60713.]—**Hose for Fire Hydrants.**—I have a private hydrant under my charge for use in case of fire. The standpipe is screwed for 2½in. brigade hose. My hose is 2in., so I reduce it at the stand pipe from 2½in. to 2in. Should I get a better supply and throw water higher with the same size nozzle if I had 2½in. hose? The pressure in

main is 35lb. to the sq. in. I should feel obliged if some kind reader of "ours" would give their experience to—WATCHMAN.

[60714.]—**Testing Ventilators.**—Will one of "ours" kindly inform me the method they have of testing ventilators that are fixed on the roofs of buildings, such as Boyle's or Buchan's?—GEORGE MCFARLANE.

[60715.]—**Motor for Canoe.**—I have a Canadian canoe that just holds two, in which I want to fix a motor of some kind. It does not draw enough water for a screw, and paddlewheels are out of the question, so I thought of fixing horizontally two small force pumps to propel the boat by forcing water out of two pipes, one on each side of the rudder. The pumps could be worked by the occupant with two levers, one in each hand. Will someone say what should be the size of the pumps and the probable speed of the boat? Would one large pump do instead of two small ones, and would it be necessary to have an air chamber? Is it the quantity, or the force, of the water that propels the boat?—ANGLO-CANADIAN.

[60716.]—**Choral Top.**—A toy called the "choral" top is now quite common. It consist of a large humming top of a brilliant white metal, containing a circular plate, to which are fitted a number of cheap acordion tongues, or vibrators. When the top is spun, a soft chord is heard, which soon changes to another chord, and at intervals the chords change. Now I would wish to know of what metal is the top made? Is it a homogeneous white metal, or is it some kind of alloy subsequently nickel-plated? The colour is very good, and the polish brilliant. It is evidently spun in two or more pieces on the spinning lathe. Can a flat dish of metal, previously nickel-plated, be spun in the lathe without destroying the nickel-plating? By what contrivance is the chord made to change automatically while the top is spinning?—S. S.

[60717.]—**Hot Dynamo.**—TO MR. BOTTONE AND MR. EAVES.—We have a dynamo at our place—a six-pole machine, Elphinstone and Vincent. It drives 150 lights, being a 400-lighter. The brushes and collector heat very rapidly after starting; also magnets heat so much that at the end of five hours run we can only just bear to touch them. How is this? The brushes go like tallow candles. Is it because of being shunt wound too much current runs through the shunt coils. Would more lamps in circuit stop this? It sparks badly. The lamps are 50-volt, two in series, then arranged in parallel arc. A friend of mine said it is caused by there not being sufficient lamps in circuit, causing too much current to run through shunt coils. Engine tenter said it was not so, because if more lamps were put in it would cause more current in the magnet coils and more heating in them. Which is right? I think the first. The machine runs at 720 a minute.—FIREMAN.

[60718.]—**In Beat.**—TO "F. W.," "ALFOJOE," OR OTHERS.—I have seen in a back number that a correspondent put a watch into a saucer and the beat was clear and distinct. I have tried this, and fail to see the advantage. Is there any ready means of increasing the sound? I am familiar with the screwdriver between the teeth and in contact with movement.—AMATEUR.

[60719.]—**Balance.**—Will "Fellow Workman" kindly tell me if it is necessary to remove hair spring from cylinder or staff when cleaning balance? I have seen in a back number his method of protecting spring of under-sprung watches, but do not see that it is applicable to over-sprung watches. Also if it is best to oil pivots or holes, if the latter is to be done after putting together?—AMATEUR.

[60720.]—**Zirconia Cylinders.**—Are they a satisfactory substitute for lime? Do they give as good a light? Do they crack? Will they stand good pressure of mixed gases? Must they be revolved? Are they durable and thoroughly dependable? Must they be kept air-tight when out of use?—LIME-WEARY.

[60721.]—**Push.**—TO MR. E. THORNTON.—I am desirous of fixing electric bell connection to large gates at a works entrance, and I wish to have a push that shall ring three bells from the one wire and one battery; bells to be in different places; total length of wire (to be overhead) 370 yards, bells to be 4in. dia.? Can I not use something much lighter than the iron wire used by telegraph companies?—ACCRINGTON.

[60722.]—**Astronomical.**—(1) By what t are $\triangle c$ and $\triangle c'$ multiplied to produce $t\triangle c$ and $t\triangle c'$ respectively? The Greenwich nine-year catalogue for 1872 gives the $\triangle c$ of γ Orionis $= + 0{\cdot}002$, and $\triangle c' = + 0{\cdot}04$. In finding the $t\triangle c$ and $t\triangle c'$ of this star for—e.g., 1 Nov., 1886, how must I proceed? (2) Why is it that the correction of R.A. of stars of southern declination comes out greater when using the independent quantities than when employing the B.A.C. constants with Bessel's day numbers, or the Greenwich constants with Airy's numbers?—VEUTON VEOR.

[60723.]—**Temperature.**—For reduction of barometric heights, C. scale, is 5508 the co-efficient to be substituted for that of 9990 F.?—POSTULATA.

[60724.]—**Circular Saw Bench.**—Would our friend, "O. J. L.," or any of "ours" who have had experience, tell me which would be the best arrangement to get power to drive a circular saw? I have got a wooden bench and saw spindle. What I should like to know is which is best, treadle and gear, or belt and pulley with large flywheel? If by treadle, what size wheels and best pitch should I require to get a speed on the saw of 1,000 revs. a minute? It is only to cut pine $1\frac{1}{4}$ deep, nothing thicker.—J. C. D., Liverpool.

[60725.]—**Insulation.**—Would any of your correspondents please inform me if there is any rule relating to the thickness of the insulation on electrical wire, or whether there are any conditional reasons why some wires are loosely covered and some comparatively tight, some covered with a single layer of cotton and some double? Others again are covered with flax, and more with silk, some of which you may press your thumb nail through and expose the wire $\frac{1}{8}$in. or more. Why not insulate small wire with cotton? Why use silk? Would a wire perfectly covered with No. 50 cotton answer as well as if it was covered with No. 16 cotton? What is the object of double covering?—PERPLEXED.

[60726.]—**Cement.**—Can any reader inform me of a cement for fixing leather to cloth under following conditions? Cement will not undergo any strain, but must be waterproof and applied to the leather only; when set the articles to be united by the application of warmth.—D. W. W.

[60727.]—**Government Returns.**—Could any reader say whether there is any book published for the information of the public containing the lists of expenses incurred by the Government in institutions or establishments throughout the country—for example, the expenses in connection with the Royal Indian Eng. College?—COOPERS HILL.

[60728.]—**Steel or Iron Tubes.**—Could any of your readers kindly give me a rule for finding what thickness of metal is required for making wrought-iron or steel-riveted tubes of a given diam. to stand a given internal pressure? A few days ago I wanted to know what thickness to make a 12in. dia. single-riveted iron pipe to stand a pressure of 90lb. per sq. in. I asked three friends. One said $\frac{3}{8}$in. plates, another 3-16, and the third 17 W.G. Now which is right? Should be glad if any of your readers could tell me. Also a 16in. dia. single-riveted steel tube to stand a steam pressure of 30lb. per sq in. What thickness should it be?—PERPLEXED.

[60729.]—**Driving Belts.**—What amount of slip is generally allowed in belts per foot per H.P. transmitted—i.e., a 5in. belt 38ft. long drives a 7in. pulley 1,600 revs. from a pulley 50in. about 20H.P.? Is 10 per cent. sufficient to allow in this case for slip?—MILLER.

[60730.]—**Turning Small Cylinders.**—Is it possible for me to turn true a small steam cylinder 1in. dia. on a very small lathe which has no tool holder—that is, in which the tools are held in the hand? If I can do so, will someone kindly tell me how to fix it?—COLOMBO.

[60731.]—**Drill for Small Work.**—(26340 p. 132.) I was going to make a small drill myself, but was puzzled how to fix the lever for raising drill. I saw your sketch, but cannot exactly see how you attach your lever. If it is not too much trouble, will you explain this, for I am rather dull?—COLOMBO.

[60732.]—**Gas-Engine.**—As gas-engines are now coming to the fore, and are superseding steam-engines for small powers, I think it would be acceptable to many to have some practical and theoretical instructions on them. Perhaps some of your numerous correspondents will supply them. In McGregor's book it says: "The combustion is faster, and consequently the explosion pressure is greater, as the velocity of the expansion increases." Does that mean as the speed increases? It also says: "The efficiency of a hot cylinder is greater than that of a cold one." Then why cool it? In what way does the Otto fall short of the ideal gas-engine? Can anyone sketch Whitworth's machine for measuring to millionths of an inch?—GAS ENGINE.

[60733.]—**Take a Postcard.**—Would someone kindly say what is to prevent some evil-disposed person from making coins in lead of the same size and weight as pennies, and inserting them into the postcard and paper envelope and stamp boxes placed about the streets of Manchester and elsewhere, and thus obtaining the same merely at the small cost of old lead, instead of the coin of the realm? If exact size and weight is necessary, of course a solid lead penny would weigh more than the same size in copper; but a core of some light material might be cast in the lead pennies, thus making them of the same size as copper pennies and of the same weight.—G. M. S.

[60734.]—**Wimshurst Machine.**—Would Mr. Bottone kindly say why it is necessary to varnish the discs of a Wimshurst machine? Also, should they be varnished on both sides? Should the sectors be fixed on the outer side only of the discs? In his directions given in last issue of "E. M.," he says leave $\frac{1}{4}$in. of clear glass between the periphery of the discs and the circle of the sectors. Is this portion of the disc not to be varnished?—AMATEUR.

[60735.]—**Electric Gas-Lighter.**—Would Mr. Bottone kindly give instructions for making an electric gas-lighter on the induction principle?—AMATEUR.

[60736.]—**Small Light Magnets.**—In constructing an article, I want a few permanent magnets about as powerful as 6in. horse-shoe ones; but unless they weigh about one quarter of their (the horse-shoe ones') weight only, and be, say, 4in. long by any breadth inside of 4in., they are of no use to me. Can such light magnets be made by any means, and at the same time be powerful enough to raise about 1oz. to $1\frac{1}{2}$oz.? I do not want them attached to a galvanic battery.—A. G. G.

[60737.]—**Mathematical.**—Solve the following equation:—

$$x^3 - y^3 = a$$
$$x + y = b$$

a and b are known numbers. Find the value of x and y in a and b.—A. CLEGG.

[60738.]—**Great Eastern Engines.**—On page 394, Vol. XLIII., "Baltimore" mentions a report of some new single engines coming out on this line. Perhaps someone can kindly say if this is so, and if any are likely to commence running shortly.—W. H. THURLOW.

[60739.]—**Continued Fractions.**—Can anyone explain how to calculate logarithms by means of continued fractions? I believe it is explained in the second volume of Francœur's "Mathematics"; but the book is very old, and I have not been able to obtain a copy.—R. E. F.

[60740.]—**Universal Chuck.**—Will any reader kindly explain how the square jaws with triangular notches, figured at page 232 of Holtzapffel's fourth volume, are prevented from travelling on their round centre pins when holding work?—R.

[60741.]—**Mensuration.**—What is a ready means of ascertaining whether a vessel having the shape of a truncated cone is approximately half-full of liquid, and does it matter whether the smaller or the larger diameter is the base? A practical method is required, without the aid of any apparatus.—CONIC SECTION.

[60742.]—**Propeller for Launch.**—What diameter and width across the blade, screw propeller (four blades), would a two-cylinder engine, 4in. stroke, 2in. bore, drive, working at a pressure between 80lb. and 100lb., and at what angle with the boss should the blades be set? Also how to work out this query: What length and beam (depth no particular consequence) load for sea use in fine weather would the above engine drive effectively?—A FITTER'S APPRENTICE.

[60743.]—**Cast-iron Piston Rings.**—Will any of my brother readers assist me in the above? How are they put on the piston? Are the pistons made in halves? Which way are they drawn? Wilson's are drawn by laying the rings on the anvil and tapping the inside edge with a hammer. Are the cast-iron rings drawn the same way? Diam. of piston, $8\frac{1}{4}$in.; ring, $\frac{1}{2}$ by $\frac{3}{8}$ thick.—H. W. G.

[60744.]—**Question in Dynamics.**—Can any reader solve and explain the following problem? A weightless string passes over a pulley (neglect both weight and friction). To one end is fastened a weight, of mass m; to the other a monkey, also of mass m, clings. The monkey suddenly begins to run up the string with velocity. What will be the resulting motion?—HUMBUGGED.

[60745.]—**Lead Valley.**—I have a valley on my house laid with 6lb. lead, and descending at a swift slope. The heat of the sun has caused the lead to blister and then crack in several places, and although I have had it several times repaired with solder it still leaks when winter comes on. A valley board would be unsightly, and it would be a serious matter to rip up the roof and lay new lead. Perhaps some kind reader can suggest a remedy.—DOCTOR MEDICINÆ.

[60746.]—**Valves.**—I am anxious to find out a really reliable full-way 6in. valve which shall be efficient under a pressure of 50lb. of steam and yet be readily opened and closed. Will some of the readers of "Ours" kindly give me their experience of those made by J. Hopkinson and Co., of Huddersfield?—FITTER.

[60747.]—**New Caledonian Single Engines.**—Will some correspondent kindly say if it is correct that these engines are the first combining in their design single driving wheels, inside cylinders, and a leading bogie, and also give a sketch of same? I notice principal dimensions have been given on pages 20 and 43 of present Vol. and page 538, Vol. XLIII. Have any of them yet commenced running on the fast-through Scotch trains?—W. H. THURLOW.

[60748.]—**Electricity at the Science and Art Exams.**—Will any of "ours" kindly say what qualifications are necessary to pass the advanced stage in "electricity and magnetism" in connection with the Science and Art Department? Is any mathematical knowledge necessary? Is the examination a stiff one? Any particulars bearing on the subject will be esteemed a favour. I may add that I passed the elementary stage a few years ago.—ZERO.

[60749.]—**Chamber Organs.**—Will "G. S." (letter 26364) say on what principle he has scaled the pipes in his answer to Mr. G. Landel, as the octaves do not appear to follow the same ratio?—F. F. R.

[60750.]—**Glass for Fish Tank.**—What thickness of glass shall I require for tank of 6ft. cubic capacity?—A. B. C.

[60751.]—**Wiped and Blown Joints.**—Will Mr. P. J. Davies tell me the reason the New River Water Co. will not allow a blown joint on their connections when it is well known they are stronger than the wiped joints?—YOUNG TURNER.

[60752.]—**Turning Balls.**—I have 25 gun-metal balls to turn of the following diameters: Five $2\frac{1}{4}$in., five 2in., five $1\frac{1}{2}$in., five 1in., and five $\frac{1}{2}$in. They are for valves. I have a lathe, no slide rest, but plenty of tools and chucks; but I lack the necessary knowledge. Will any practical sub. kindly assist?—YOUNG TURNER.

[60753.]—**Light.**—TO W. G. PENNY.—Referring to end of letter 26361, when looking at a star, are the rays more perpendicular to the retina than when looking at the side of it? The retina is not flat, and, besides, the rays in both cases are all oblique (except the centre one).—M. YORK, M.I.C.E.

[60754.]—**Artificial Horizon.**—What would be the simplest way to make an artificial horizon? Would water in a vessel, covered with either gauze or muslin, do to protect it from the wind? What would be the best way to fix either muslin or gauze? Any hints will be useful.—JACK.

[60755.]—**Professor Trusses' Valves.**—Will Mr. P. J. Davies, or any sub., kindly tell me the action of the above ball, bib, stop, and water-waste preventers for closets? Are they durable when made properly, and do Farmiloes, of Clerkenwell, supply them, and can the joints be wiped or blown without taking them to pieces?—YOUNG TURNER.

[60756.]—**Battery and Lamp.**—Will Mr. Bottone kindly aid me in the following? I wish to construct a battery to work incandescent lamp, sufficiently powerful to admit of reading comfortably, at about 2ft. or 3ft. distance. I do not want to charge more than once a week, using it two hours each night. Can you suggest anything that will meet the above case? As regards the solution, please let me have the solids by weight and the liquids by measure; also the smallest size and number of plates and jars necessary to satisfactorily accomplish the end in view.—THORS.

[60757.]—**Revolving Wood Stand.**—I wish to make a circular revolving wood stand of three tiers for light fancy articles in shop window, 18in. diam. at base. I shall be very glad if anyone will kindly give me advice (and sketch) (1) how to make, and also (2) whether an electro-motor would be suitable for working it, and (3) whether two Fuller's cells would be sufficient to run a motor for the purpose.—REVOLVER.

[60758.]—**Small Launch.**—I am making small launch for river, 12ft. long. Can any reader tell me if I could burn petroleum instead of coal in firebox, and how? I propose using vertical boiler about 3ft. by 18in.—PETROLEUM.

[60759.]—**Aniline Dyes.**—What will discharge a stain in white flannel caused by one of these dyes? Chlorine, chloride-of-lime water, and the chloride itself do not bleach it. The last has made the stain worse, and has made the unstained part yellow, and it formed a soapy lather when applied.—J. S. C.

[60760.]—**Boehm Flute Making.**—TO "VULCANITE" AND OTHERS.—I thank you for your two replies to

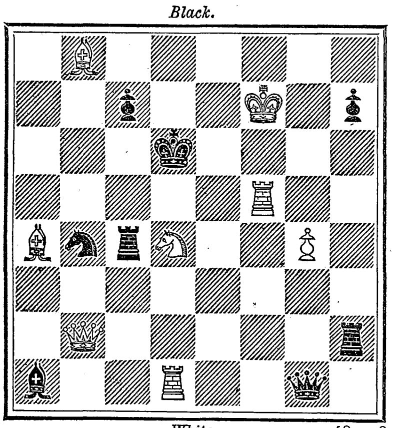
my former queries; but as it is not practicable for me to advertise my address, and as I require full directions, I hope you will be kind enough to write a letter on the above subject.—J. G. BARTEL, Nelson, New Zealand.

CHESS.

ALL Communications for this department must be addressed to J. PIERCE, Langley House, Dorking.

PROBLEM MXIV.—BY E. J. WINTER-WOOD.
(From "Chess Souvenirs.")

Black.



White. [8 + 8

White to play and mate in two moves.

SOLUTION TO 1,012.

White.	*Black.*
1. B-Kt 5.	1. Q takes B (*a*).
2. Q-Q 6 (ch).	2. K takes Kt.
3. Kt-K Kt 2, mate.	
	(*a*) 1. P takes Kt (*b*).
2. Kt-B 3, &c.	
	(*b*) 1. Kt takes Kt (*c*).
2. Kt-K 7 (ch), &c.	
	(*c*) 1. K moves (*d*).
2. Q-Q 4 (ch), &c.	
	(*d*) 1. Kt-Q 8 (*e*).
2. Q-Kt 5, &c.	
	(*e*) 1. Any other.
2. Kt-B 3 (ch), &c.	

NOTICES TO CORRESPONDENTS.

CORRECT solutions to 1,012, by A Beginner. G. T. Stringfellow (but 1. $\frac{\quad}{\text{P takes Kt}}$ wrong), A. Dean, A Beginner; to 1,011, by J. Thompson, G. A. A. Walker. Avon, G. T. Stringfellow, A. Bolus, A Beginner.

J. MACKENZIE AND G. A. A. W.—The reference was to 1,009.

G. T. STRINGFELLOW.—How do you mate in two moves altogether if 1. $\frac{\quad}{\text{B-R 4}}$? By second solution we intended to indicate that the author's solution was not sent. Your other attempts seem failures, as if 1. $\frac{\text{Q-Kt 6}}{\text{Kt-Q Kt 6}}$, and if 1. $\frac{\text{B-Kt 6}}{\text{Kt-Q Kt 6}}$, how do you proceed with these defences?

WHITE PAWN.—You have not given Black his best defence in your attempt at 1,012. If 2. $\frac{\quad}{\text{K-K Kt 5}}$ there is no mate. Again if 1. $\frac{\text{Q-Q Kt 5 (ch)}}{\text{K takes Kt}}$, and how then?

A BEGINNER.—We do not think the solution to 1,011 was received; but, after your statement, we have allowed you full marks for it. We have noted your corrected solutions of 1,012.

American Guns.—The United States Ordnance Department is much pleased, the *Army and Navy Register* says, with the performance of the new 8in. steel gun at Sandy Hook. "This gun, which weighs 13 tons, and whose length of bore is 30 calibres, was manufactured at the West Point Foundry. The tube and jacket were obtained from Whitworth, and the hoops and the breech mechanism forgings from the Midvale Steel Company. The gun was first tried with the German brown prismatic powder, when the following results were reached:—With a charge of 100lb., and with a shot weighing 182lb., the muzzle velocity was 2,145ft., and the pressure 29,500lb.; with a 235lb. shot the velocity was 1,942ft., and the pressure 32,250lb.; with a shot weighing 286lb. the velocity was 1,795ft. and the pressure 32,800lb. The gun was next tried with Du Pont's brown prismatic powder, the charge being the same. The velocity with a 235lb. shot was 1,937ft., and the pressure 32,950lb.; with a 286lb. shot the velocity was 1,820ft., and the pressure 35,450lb. The gun has been fired thirteen times, and will now be turned over to the Testing Board. It is worthy of remark that when this gun was designed the computed velocity with the 286lb. shot was 1,825ft., and the computed pressure 36,000lb. This is almost exactly verified by the firing with the Du Pont powder."

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, Oct. 20, and unacknowledged elsewhere:—

R. C. MOORE.—A. J. Herbert.—Mawson and Swan.—W. H. Nelis.—E. Broderip.—H. Dowsett.—H. Le Brasseur.—A Regular Reader.—E. Conry.—Flavius.—W. Drechsler.—Geo. Bell.—Manchester.—J. H. D.—Student.—B. R.—A. L. K.—Volta.—Geo. Landel.—G. W. A.—E. L. G.—F. L. Striffler.—D. Gillies.—H. Sadler.—J. E. Gore.—J. Wimshurst.—H. D. R.—W. H. Hardie.

PRACTICAL. (There are many recipes in back volumes, but no doubt the numbers containing them are out of print. You do not mention what colour is required, but a good pale lacquer can be made by dissolving seed lac in pure methylated alcohol, and adding dragon's blood, saffron, annatto, aloes, or gamboge to colour. A common recipe is to one gallon of methylated spirit add 5oz. of shellac, 4oz. of sandarac, and 1oz. of elemi; expose to a gentle heat for a day or two and strain. Add half a gallon of spirit to the sediment and treat as before. Unless wanted in large quantity it is always cheaper to purchase lacquers of the kind required.)—W. R. D. (The sun does not "put the fire out." The contrary assertion is easily disproved by an experiment, but unfortunately there is not much sun now.)—A. W., OLDHAM. (A fragment of sodium is inclosed in the tinfoil.)—L. FINCH, LONGFIELD. (We have not seen one, and so can express no opinion; but xylonite seems a suitable material for such a purpose.)—M. P. (Britten's "Watch and Clockmaker's Handbook," Kent and Co., Paternoster-row, and Saunier's "Watchmaker's Handbook," Tripplin, Bartlett's-buildings, E.C. See also the indices of the back volumes for really practical instruction.)—VILLAGE ORGANIST. (Procure lists from Novello and Co. Berners-street, W., the *Musical Bouquet* office, High Holborn, and other dealers.)—H. R. (See hints Nos. 4 and 5. Such a list can be made by consulting the directories. The query is altogether unsuited to our columns.)—G. B. CRESWELL. (We do not know, but if we wanted one we should write to Prof. Pickering, Harvard College, Cambridge, Mass. Perhaps Mr. Wesley, bookseller, Essex-street, Strand, has them on sale.)—DIDO. (The surface of the lead is oxidised unless covered, and it should be skimmed off before pouring. 2. Flour rubbed smooth in water and then boiled. Add a little alum.)—AN OLD READER. (Gum is dissolved in water. What would you dissolve it in?)—H. J. AND CO. (Several electric fire-alarms in back numbers. See p. 495, Vol. XLI., and p. 12, Vol. XLII.)—PERPLEXED. (It is prepared by adding soluble Prussian blue to a good gall ink. Sulphindylate of potash or ammonia dissolved in hot water and the liquor decanted when cold.)—NOVICE. (See p. 400 last volume for directions how to relacquer.)—WEAK NERVES. (It is not beneficial to the nervous system.)—N. W. C. (Maxton's "Manual of Engineering Drawing," Crosby Lockwood and Co., Stationers' Hall-court, E.C., 3s. 6d.)—TEIGN. (Apparently a chloride of silver cell, but no one can say without inspecting it. Try a little water first.)—J. C. W. K. (Nothing better than leather—consequently nothing cheaper. Calf, oil dressed, is the best leather for smith's bellows. 2. Screws are made by machinery. Finishing with such an apparatus altogether too expensive.)—D. BOOTH. (A furnace for melting brass was illustrated on p. 373, No. 1,031. See also the index of Vol. XL.)—G. H. B. (As there is no such thing as perpetual motion, it is not easy to say what it means; but if you can make a machine which will keep on the move without anything whatever being done to it, we suppose that will be "perpetual motion," even though some of the parts may wear out. We have no space for the discussion or description you require; but you will find a good deal of information in Dircks's "Perpetuum Mobile," published by E. and F. N. Spon.)—B. ("Light" and "shade" in such a connection are not technically accurate terms; but they are well understood—the former meaning passages in which the theme rings out clearly, the other in which it is subdued by the accompaniment.)—R. W. J. (See p. 561, last volume, for an illustration, and look at Hint No. 4 above.)—A. Z. (See indices, as there are many suggestions in back volumes. A good sized sheet of black twill, lined with some yellow material, will answer if you can arrange it on temporary legs as a sort of tent.)—J. M. (Any working optician would repolish your mirrors.)—KAPLAN. (It means exactly what it says—that it is not only given to her but to her heirs, executors, &c. If she dies before you, better make a new will.)—COOPER. (Do not know of any book on patterns; but Campin's book on "Hand-Turning," published by Spon, we think, will probably answer your purpose.)—A. B. H. FAUDELLE. (Watt's "Electro-Deposition," Crosby Lockwood and Co., Stationers' Hall-court, E.C. 2. No other that we know of, as you qualify the question by the word "Home.")—A FITTER'S APPRENTICE. (You can get at the flue tubes from the firebox; but as to the water tubes, better ask the maker for his idea how they are to be cleaned; perhaps they can be taken out. It seems rather a peculiar boiler, for the furnace flames can play on the unprotected metal of the shell, according to your drawing. Surely the plates are protected by water.)—JNO. T. LAWTON. (Nos. 605, 608, 611 contain papers on the Magic-Lantern—how to make and use it. They are out of print, but may possibly be obtained from Mr. Sladen, 33, Cank-street, Leicester.)—JNO. GLOAG. (See previous answer. No work giving details of construction.)—J. S. W. (See p. 419, No. 1059. Clean the bones from all flesh, put into running water, and bleach in the sun.)—IGNORAMUS. (You will find all about the "storm-glass" in back numbers, especially in No. 1059, p. 405.)—J. W. R. (We believe we answered you not long ago. Such portions as are suitable for insertion have been answered many times. See indices, and the Hint No. 4 above.)—YOUNG IRONFOUNDER. (No; bisulphide of carbon is not "animal carbon." The latter is obtained by subjecting any carbonaceous substances of animal origin to heat while protected from the action of the air.)—QUIS EST. (See the various works on Astronomy likely to deal with such a subject. It may be said to seem certain that the earth will eventually be something like its moon.)—DOUBTFUL. (It depends on the price of gas; but there are many mills and factories now lighted by electricity, with economy, or, at least, with advantages which gas does not give.)—W. A. (The question has been answered over and over again, even in recent numbers. For a suitable battery, see p. 561, No. 1117.)—TRITON. (If received, it will be inserted or acknowledged.)—ARTHUR M. EDWARDS. (We do not remember a letter; but a query on the subject was received, and appears on p. 162, No. 60640.)—TRANSFER. (A similar question was answered so recently as Sept. 24, p. 90.)—HEATH. (Study the principle in any textbook. It consists of a tube in which are three mirrors running along the length and inclined at an angle of 60°. One end is closed with a cap containing a ground glass cell with small bits of coloured glass, and the other with a cap having a hole in its centre. The Debuscope has only two mirrors, which are simply pieces of glass blackened on one side in the common toy.)—WINDERMERE. (If you have not access to back numbers you will find most of your electrical questions answered in the textbooks. They have been answered in recent back numbers. There is no advantage in the use of asbestos. The cost varies with the place. Apply to dealers. Paraffin wax has been recommended for coating wooden vessels, and so has a mixture of guttapercha and pitch. You cannot treat vulcanite in that way. As to the ecclesiastical questions, you should consult the secretary of the bishop of the diocese in the one case, and the table in the Prayerbook in the other.)—SOLAR RADIANCE. (Would it not be better for you to procure the publishers' lists? Try Piper and Carter, 5, Furnival-street, Holborn, E.C.)—G. R. (You will find an illustration of an improved Æolian harp in No. 1048, p. 163.)—COMUS. (For glazing photographs see p. 345, No. 1108; the indices generally, or any of the cheap manuals. 2. Was not the tube at the South Kensington Museum marked? See pp. 414, 425, Vol. XXXVIII. Decoction of the bark of the horse-chestnut, and solution of sulphate of quinine, alcoholic tincture of chlorophyll, of the seeds of stramonium, and of turmeric.)—R. (It is scarcely likely that any bona-fide reply would be received. There are two engines of the kind in the market which you can, we believe, see at work.)—P. R. I. (See the first answer on p. 141, and apply to the Superintendent, Steam Reserve Office, Chatham.)—J. J. K. S. (If you want a lamp, see p. 395, Vol. XXXIII.; but if a furnace, look at the illustration of the Shipman engine on p. 419, No. 1087. 2. They are all hydrocarbons—that is all that can be said without examination, as trade names define nothing at all in that connection. Petroleum should mean the crude oil—kerosene and paraffin the refined or "burning" oils.)—C. R. (It is not illegal to quote mere "passages" from an author's works; but when they are likely to be numerous or extensive it is only courteous to ask his permission if they are to be published in another work.)—CONSTANT READER, America. (Try G. L. Fairbanks, Worcester, Mass., or Fay and Scott, Dexter, Maine, for the lathe; but as to the castings of model engines, it might be cheaper to get them here, unless you want a quantity.)—R. SMITH. (A thumb-screw for attaching any article to a table or other support is rather too old to form the subject of a patent, or even a claim in a patent.)—OMPAX. (1oz. avoirdupois is equivalent to 28·34954 (say, 28·35) grammes.)—NASAL. (Red noses are produced by indigestion more frequently than by drinking. The only cure is to remove the cause, and you do not give any idea of what that is.)—S. ARLIDGE. (From any dealer in metallurgical specimens, or from the foreman of any lead mine.)—F. M. (You first issue a summons; the case is heard; if proved, the judge will order the defendant to pay in a week. If he does not pay, you issue an execution on his goods; if he has no goods, you apply for a judgment summons, and the case comes again before the judge, who, if satisfied that the defendant can pay, will commit him to prison in default. The committal does not cancel the debt.)—ANXIOUS. (In type.)

The English Mechanic

AND WORLD OF SCIENCE AND ART.

FRIDAY, OCTOBER 29, 1886.

NOTES ON THE CHAMBER ORGAN.—VII.

By GEORGE ASHDOWN AUDSLEY, F.R.I.B.A.

HAVING in the preceding six articles touched upon matters relating to the general appointment and disposition of the Chamber Organ, as I desire such an instrument to be understood; and having enlarged somewhat on special details connected with its tonal structure, and the means to be adopted to impart the maximum powers of expression to its different departments; I may, in conclusion, direct attention to some remaining matters of not a little importance and interest. I shall, out of consideration to my readers, be as brief and direct in my remarks as possible.

Internal Design.

It is almost needless to remark that in connection with an organ for the reception or accommodation of which so little floor space and height are commonly provided, the greatest ingenuity and care must be expended in internal planning and arrangement. Let there be a studious avoidance of unnecessary complexity and crowding in any part; and let every exercise of skill be resorted to to arrive at the simplest forms of mechanical action. Do what one may, a Chamber Organ, with only two manuals, pedal clavier, two swells, and the full complement of couplers and other mechanical accessories, must turn out to be a seriously complicated affair—difficult to put together in its most perfect form; and, unless most beautifully made and of the finest materials, difficult to keep in satisfactory working order. It is not too much to say that absolute perfection of material and workmanship must obtain throughout; and that nothing must be passed over carelessly as of minor importance, for the use of the smallest piece of unseasoned wood, or the careless fitting of the most insignificant pin, may cause a train of annoyances, and the loss of temper and much valuable time.

In all matters relating to the construction of the organ, the builder, professional or amateur, should neither be "penny wise and pound foolish," nor pound wise and penny foolish. The saving of a penny may cause pounds of unexpected and unnecessary expense. To summarise the matter, the following six golden rules may be addressed to the organ-builder:—

1. Use, from first to last, the best and most suitable materials money can buy, for such a course is cheapest in the end, and altogether the most creditable.
2. Do not leave a single article in an unfinished or slovenly state. Whatever you do do with all your might.
3. Put everything together accurately and securely as if your life depended on the successful result of your work.
4. Protect everything liable to become impaired by the action of damp and dust by the best means which can be devised for that end.
5. Reduce the friction of all moving parts to the minimum, and take all precautions to prevent noise and undue wear.
6. Give every article as graceful and as pleasing a form as is compatible with its utility, for there should be beauty as well as morality in every work of a true artist. Whatever is worth doing at all is worth doing well.

On purely practical details connected with the mechanical and constructive parts of the Chamber Organ I do not at present propose to speak; but, in contemplating the internal design of the instrument, I may advise careful attention to be paid to the planting of all pipes, and to the provision necessary to be made for their convenient tuning. In both these directions Chamber Organ builders have too often displayed want of thought and sense. I cannot, however, say they are invariably to blame, for a deficiency of adequate space for the instrument has too often rendered internal cramping and crowding imperative. Let it be understood, once for all, that a cramped and crowded Chamber Organ can never be a successful instrument from a musical point of view; and those who insist on having a large instrument in a position totally unsuited for it must not marvel if it proves unsatisfactory. On this subject, I cannot give better advice than this: If the room is built, let an organ be constructed to suit the room; if the organ is constructed, let a room be built to suit the organ.

Notwithstanding my resolution to avoid speaking of purely practical matters, I feel it is desirable to say a few words respecting those portions of the Chamber Organ, on the proper construction of which the power of expression of the instrument chiefly depends. I allude to the swell-boxes.

There are two conditions on which the excellence of a swell-box depends—namely, its capabilities of confining sound when closed, and giving it free egress when opened. To secure the first condition of excellence it is necessary that the entire box should be carefully constructed of materials which are bad conductors of sound. The most convenient materials are wood, felt, linoleum, straw-board, and thick brown-paper. The best way of using these will shortly be hinted at. Great thickness of material is not so necessary in the swell-boxes of Chamber Organs as in those of church and concert-room instruments, in which high pressures of wind and loudly-voiced stops are introduced. While sides and tops of 3in. in thickness are necessary for the swells of the usual types of church and concert instruments, those for the swells of Chamber Organs are ample at $1\frac{1}{2}$in. to 2in., especially if a proper mode of construction is followed.

For a Chamber Organ swell-box, the sides and top may be formed of $1\frac{1}{2}$in. thick framed and flush-panelled pine; covered, on the inside, with several layers of stout, fibrous brown paper, securely pasted on, and painted with four coats of oil paint and well varnished. The hard, glossy surface thus produced becomes a good reflector of sound. If the swell-box is out of sight, or does not require to be treated in any ornamental fashion, the addition of a covering of linoleum, well-glued and tacked on the outside, or coatings of brown paper, painted, will prove of great advantage. A more satisfactory swell-box may be made of sides and top formed of two 1in. thicknesses of wood, screwed together with a layer of thick, coarse felt between them. The inside should be papered and painted, as before directed. Stout straw-board or linoleum may be used instead of the felt, but not with so good a result.

The shutters or louvres should be made of wood not less than $1\frac{1}{2}$in. in thickness, and have thin felt on their edges. They should invariably be made to open towards the room, so that the sounds from the pipes may come directly on the ear. This is an all-important matter, for if they open in the contrary direction, the most refined *nuances* are quite lost, and much of the brilliancy of the swell is destroyed. Too much thought and care cannot be devoted to the construction of the swell boxes of a Chamber Organ. Let the reed stops be planted close to the most accessible sides of the swell-boxes; and let small doors be provided which can be removed for tuning without otherwise opening up the boxes. The great convenience of such an arrangement is obvious. As balanced Expression levers are used, the louvres should in all possible cases open vertically. When horizontal louvres are imperative, the action must be balanced by a counterpoise, and a certain amount of friction put on the connecting rods to prevent any swinging or undesired return.

However well an organ may be built, it is in the nature of things that it should require frequent attention and tuning, and occasionally adjustment and repairs. To render these operations easy, care should be taken, in planning the interior of the instrument to provide ready means of access to all parts. It should never be necessary to remove one part to get at another, or to disarrange one portion to readjust an adjoining one. Special conveniences for tuning should be schemed, otherwise much annoyance and disappointment will accrue.

External Design.

As an architect, it may reasonably be expected that I should go at some length into the subject of the artistic treatment of the exterior of the Chamber Organ; but I confess it is with some reluctance that I essay to pass even a few remarks on it, simply because it is a subject far more vast and complicated than anyone unacquainted with designing and decorative art can at first thoughts realise. Besides, in all such matters tastes differ so widely, that what to one man is pleasing is, very probably, to another man objectionable. I shall, however, not go into any questions of style in these Notes; but confine myself to a few remarks of very general application.

It will certainly be conceded that a Chamber Organ, on the construction of which the greatest skill and a considerable sum of money have been expended, should be a work of art, and that refined taste should set its seal on a work of so much thought and labour. What do we observe in the generality of cases? Let my readers think of the Chamber Organs known to them, and answer the question. I would rather not waste space by giving the results of my survey in answer thereto.

In designing the exterior of an organ, the artist should recognise all the conditions imposed by the peculiar nature of the instrument. He should neither make it look like a Grecian temple nor a Gothic church. The peculiar features of an organ are its pipes—conventional objects, which admit of no liberties being taken with them in matters of form or size beyond very circumscribed limits—and these the artist, both for the sake of his own honour, and the utility of the instrument, must make much of. He is the greater artist who best fuses these stubborn materials into his alloy of artistic elements.

It is the duty of the organ builder to place at the disposal of the artist pipes beautifully made of perfect materials; and it is the duty of the artist to arrange and combine them, in his conception, so as to produce a harmonious design, and to decorate them, when decoration is required, in a manner consistent with their forms and materials. Pipes formed of tin or fine "spotted metal" require little or no decoration in gold and colours; but they should invariably be protected by a coating of colourless oil varnish. Partial decoration in gold and colours, with the bright metal as a ground, has a pleasing effect. It must, however, be applied with great judgment and taste, so as to appear as if it belonged to the pipes. Wooden pipes, on the other hand, absolutely demand the labours of the decorator, and admit of many modes of treatment. When they occupy prominent positions in the design, they are best gilded, on their exposed faces, and delicately diapered or otherwise ornamented with black, brown, or some such dark colour. Any light, quiet tint may be

used instead of gold as a ground for the ornamentation.

If the pipes are beautifully made of some choice and nicely-coloured wood, they may be varnished only, and the black or other coloured ornamentation applied directly to their surface. Such a treatment is a perfectly consistent and rational one, and may reasonably recommend itself to all lovers of simplicity and truth. In the construction of all wood pipes which are intended to be displayed, great attention should be given to their general finish, and to the formation of their mouths and caps, and also of their feet if they are to be shown. By the exercise of a little taste, a row of wooden pipes, usually a very commonplace affair, may be made to speak the language of art as well as pleasant musical sounds.

The association of metal and wooden pipes in one design has a very pleasing effect, and, to my eyes, it is preferable to that produced by the exclusive introduction of cylindrical metal pipes. But, as I have already said, this, like other matters of design, will always remain a matter of taste and opinion. I have fairly tested the combination in the external design of my own organ, and I venture to think with a satisfactory result.

In the matter of case-work a great diversity of opinion is certain to obtain. Some persons hold that there should be hardly any beyond that absolutely necessary for the inclosure of the mechanism and claviers, while others believe in an elaborate system of case-work, inclosing everything save a few small metal pipes, displayed with the purpose of preventing the organ being mistaken for a huge wardrobe or some such formidable piece of furniture; perhaps, the golden mean between both of these extremes is most desirable in nine cases out of ten. It must be borne in mind that the great use made of the swell-box renders a further wholesale system of inclosure unnecessary, if not positively destructive to the tone of the organ; and that if the swell-box is ornamentally treated a further casing is not desirable on purely artistic grounds. There is no difficulty in making the swell-box a very ornamental and pleasing feature of the general design of the instrument; and even the louvres may be so treated as to assume a dignified position in the scheme of decoration.

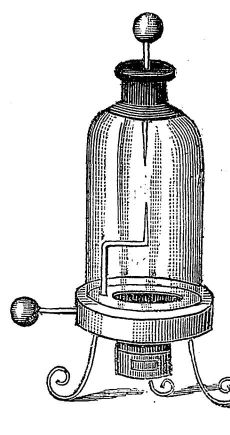
The lower portion of the organ, which contains the chief part of the mechanism, calls imperatively for some sort of inclosure; and here taste and ingenuity may display themselves. In the choice of woods, and in their combination, and in their partial decoration with appropriate musical subjects or refined ornamentation in colours and gold, the artist may show any degree of skill, and produce an almost endless variety of effects. The woodwork here and, indeed, throughout the entire instrument, must be put together in the strongest possible manner; otherwise most objectionable and irritating vibrations are sure to take place when certain pedal pipes are held speaking for a second or more. Let every joint likely to vibrate be covered with an edging of cloth, and firmly screwed or otherwise secured. Care exercised in these matters never goes unrewarded.

The position of the claviers now claims some little attention. In Chamber Organs, as in church and concert-room instruments, it is held desirable, by some builders, to locate the claviers in a "detached console," placed at a convenient distance from the organ proper. There is something to be said both for and against the detached position. Taking the disadvantages into consideration first, it will be found that the detached console is attended with considerable expense—firstly, because the action is rendered much more complicated; and, secondly, because it necessitates the floor of the room being constructed or materially altered to admit of the passage of the connecting trackers, rods, &c.;—the tubes, if the action is on the pneumatic tubular system; or the wires, &c., if the action is electric. Further, unless the apartment is spacious, the detached console, with its Pedal clavier and stool, will be an inconvenient fixture, if not an eyesore, wherever it may be placed. It is an expensive, and not altogether an easy, matter to make the console an elegant article of furniture. Now, turning to the advantages attending the adoption of the detached console, it is argued that it is favourable to the performer—firstly, because it allows him to face his listeners, or the artists he may be accompanying; and, secondly, because it enables him to realise more clearly the musical effects he is producing. These, I believe, are the only advantages which have been claimed for the detached position. Personally, I do not advocate the adoption of the detached console; for, as I shall endeavour to explain in my concluding article, there is an important advantage in the attached claviers, with their attendant simple mechanism—so great an advantage that I shall always advocate, for the Chamber Organ, the attached, in preference to the detached, position.

(*To be continued.*)

ELECTRICAL DEPOSITION OF DUST AND SMOKE.

THE remarkable behaviour of dust and smoke when subjected to a strain set up in an intervening dielectric has of late attracted much attention, and we therefore have great pleasure in illustrating a convenient piece of



apparatus designed and constructed by Messrs. King, Mendham, and Co., Western Electrical Works, Bristol, by means of which the interesting phenomenon of the deposition of dust and smoke may be produced and observed. It consists of a bell jar, through the top of which is fitted a brass rod carrying a brass ball at its upper extremity, and terminating in a point within the jar. Opposite to this is placed another rod, which passes out through the base of the apparatus. Each of these rods is intended to be placed in metallic connection with an electrode of a Wimshurst electrical machine. The bell jar is mounted on three supports, and beneath the base is a cylindrical box in metal, in which the fume can be produced. Smouldering brown paper is placed in this metal box, and when the smoke has completely filled the jar, the machine is started, and the smoke, which at first appears to be greatly agitated, is observed to be quietly vanishing, leaving the jar perfectly empty.

PAIN'S IMPROVED SIGNAL LIGHTS.

IMPROVED signal-lights for use at sea or elsewhere, which are believed to be thoroughly damp-proof, have been recently patented by Mr. J. Pain, of Walworth-road, the well-known pyrotechnist. Signals of the kind are required to be not only damp-proof in all climates, but to be free from risk of spontaneous ignition. The "red flares" are more especially applicable for use on board fishing vessels whilst trawling, but have their uses wherever signals of the kind are valuable. The ingredients specified by the patentee are:—Strontian sulphate, 6 parts; strontian carbonate, 6 parts; kowrie or copal dust, 6 parts; chlorate of potash, 30 parts; and infusorial earth, half a part. These substances are reduced to powder separately, intimately mixed, and then rammed into cases in the usual manner for making signal flares of the kind.

ASTRONOMICAL NOTES FOR NOVEMBER, 1886.

The Sun.

Day of Month.	Souths.	At Greenwich Mean Noon.		
		Right Ascension.	Declination South.	Sidereal Time.

26	11 47 30·29 ,,	16 8 51	20 59 46	16 21 21·03

The method of finding the Sidereal Time at Mean Noon at any other Station will be found on p. 353 of Vol. XLII.

Spots and faculæ now appear at rare intervals, and in greatly diminished size and numbers.

The Moon

Enters her First Quarter at 5h. 5·2m. in the afternoon of the 3rd, and is Full at 7h. 6·5m. p.m. on the 11th. She will enter her Last Quarter at 10h. 40·3m. on the night of the 18th, and be New at 7h. 18·5m. p.m. on the 25th.

Day of Month.	Moon's Age at Noon.	Souths.
	Days.	h. m.
1	5·2	4 26·4 p.m.

16	20·2	3 34·1 a.m.
21	25·2	8 4·1 ,,
26	0·7	0 28·5 p.m.

The Moon will be in Conjunction with Saturn at 1 p.m. on the 16th; with Jupiter at 1 a.m. on the 23rd; with Venus at 2 p.m. on the 25th; with Mercury at 9 p.m. on the 26th; and with Mars at 2 p.m. on the 28th.

Mercury

Is an Evening Star throughout November, attaining his greatest elongation East of the Sun (22° 29′) at 5 p.m. on the 13th. He is, however, just about as badly placed for the observer as he well can be, and, if he is to be seen at all, must be caught in the telescope in bright daylight when he is close to the Meridian. His angular diameter steadily increases from 5·4″ on November 1st to 9·6″ by the last day of the month.

Day of Month.	Right Ascension.	Declination South.	Souths.

Antares on the afternoon of the 8th; but this is the only conspicuous star he approaches.

Venus

Is a Morning Star, but is approaching the Sun, and is in that phase in which she is absolutely destitute of any interest as a telescopic object, presenting, as she does, a very nearly circular little disc of only 9·8″ in diameter. Indifferently placed for the observer at the beginning of November, her position in this respect daily deteriorates too.

Day of Month.	Right Ascension.	Declination South.	Souths.
	h. m.	° ′	h. m.
1	13 57·6	10 45·0	11 14·9 a.m.

11	14 46·0	15 4·7	11 23·9 „
16	15 10·9	17 1·1	11 29·1 „
21	15 36·3	18 46·2	11 34·7 „
26	16 2·2	20 18·4	11 40·9 „

The path indicated by the above ephemeris lies mainly in Libra, though towards the end of the month Venus will have crossed the boundary into Scorpio. On the 25th the planet will be about ½° South of β Scorpii.

Mars

Is invisible, as for the purposes of the observer is

Jupiter

too; but

Saturn

Rises before 9 p.m. at the beginning of November, and a little before 7 p.m. at the end of it; so that although, as far as his meridian passage is concerned, he is a Morning Star, yet he may be fairly well observed before midnight. His angular equatorial diameter increases imperceptibly from 17·2″ on November 1st to 18″ by the 30th. The observer will note that the rings are now sensibly less open than they were last year.

Day of Month.	Right Ascension.	Declination North.	Souths.
	h. m.	° ′	h. m.
1	7 37·1	21 17·6	4 55·5 a.m.
6	7 37·1	21 17·9	4 35·8 „
11	7 36·9	21 18·7	4 16·0 „
16	7 36·5	21 20·0	3 55·9 „
21	7 36·0	21 21·7	3 35·7 „
26	7 35·2	21 23·8	3 15·3 „

The very short retrograde arc described by Saturn during November lies wholly in Gemini, some 7° South of Pollux.

Uranus,

Like Mars and Jupiter, is invisible for the observer's purposes.

Neptune

Is in an excellent position, coming as he does into opposition to the Sun at 7 p.m. on the 18th. He is, in fact, practically visible all night long.

Day of Month.	Right Ascension.	Declination North.	Souths.
	h. m.	° ′	h. m.
1	3 40·1	17 45·0	12 55·2 p.m.
6	3 39·5	17 43·1	12 34·9 „
11	3 39·0	17 41·1	12 14·7 „
16	3 38·4	17 39·2	11 54·5 „
21	3 37·8	17 37·2	11 34·3 „
26	3 37·2	17 35·3	11 14·1 „

The almost imperceptible arc indicated in the above ephemeris lies in a wholly blank part of Taurus, about 6° South of the Pleiades.

Shooting Stars

Are, as it is very well known, both numerous and conspicuous in November. The Leonids, so-called from their appearing to radiate from the constellation Leo, are the best known, and are visible in the greatest numbers between midnight on the 13th and dawn on the 14th, although outliers of the stream may be looked for from the 11th to the 15th inclusive. The story of the connection of this stream of meteorites with Tempel's comet (Comet I.) of 1866 has been often repeated in these columns. The meteors which represent all that is left of the vanished Comet of Biela may also be watched for on the night of the 27th. They appear to radiate from a point in the north-eastern part of Andromeda.

Greenwich Mean Time of Southing of Fourteen of the Principal Fixed Stars on the Night of November 1st, 1886.

The method of finding the Greenwich Mean Time of Southing of either of the Stars in the above list for any other night in November; as also that of determining the local instant of its Transit at any other station, will be found on p. 355 of Vol. XLII. It must be noted, though, that the rules there given are not rigidly accurate as applied to Polaris, or any other close circumpolar star; although they will probably be found quite sufficiently so in practice.

THE ROBERTS PEROXIDE BATTERY.

A FORM of peroxide battery has been recently described by Mr. I. L. Roberts in the *Electrical World* (N.Y.), which may be of interest to some of our readers. Mr. Roberts says:—

It is probable that when coal is consumed in oxygen or a metal is burned in chlorine or fluorine, the action is electric, or, in other words, all chemical action first produces a current of electricity; but as we do not know how to attach binding posts to such elements, the current is not made manifest to our senses. As the currents thus made are entirely short-circuited on themselves, they produce only the phenomena of heat, as does the current in an ordinary battery when short-circuited on itself. As soon as we are able to get some way of conducting away the current from simple chemical union, then we will reach the ideal method of producing electricity. The ideal battery is one which will not deteriorate on open circuit, and will be constant on closed circuit. Both these qualities have been attained, but not in the same cell. Chromic acid as a depolariser is constant enough, while sal-ammoniac, as a single fluid, will not destroy on open circuit to an injurious extent. I think I may venture to say that the nearest approach to the ideal battery that has come before the public is one recently invented by myself and known as my Roberts peroxide battery. The main feature in this battery is the peroxide of lead which is used as a depolariser. It has been known in electro-chemistry for some time that peroxide of lead is one of the most powerful depolarisers, as used, for instance, in the secondary battery. But no commercial use has been made of it in primary batteries; because, first, it was a powder and difficult to apply to the purpose; and, secondly, it was too costly to put into competition with peroxide of manganese, which, though not so good, was cheap. It was the writer's fortune to discover how to make it cheap enough and solid enough to far outstrip manganese dioxide as a depolariser. It is made by adding to red lead, permanganate of potash in a powdered form and well mixing them. To this there is added any acid which will decompose the permanganate, such as sulphuric, or preferably hydrochloric acid. This will unite with the alkali and liberate the permanganic acid, which is the

most powerful oxidiser known to chemists. This will immediately unite with the red oxide of lead, Pb_2O_3, and produce PbO_2. The whole mass, if properly made, is in a semi-liquid form, and if poured into a mould containing a carbon, it will set in a few seconds. The mould can be opened, and the whole removed and dried, when it will be porous like a carbon and will be a conductor of electricity.

RECENT RESEARCHES ON FRICTION AND THE ACTION OF LUBRICANTS.—III.*

By PROF. HELE-SHAW.

OUR knowledge of the friction of dry surfaces at high speeds is chiefly derived from experiments on railway brakes, some of the most important being those of Poirée and Bochet in France, and Captain Douglas Galton and Mr. Westinghouse in this country. Both these sets of experiments show that at high velocities the friction of such surfaces is very much reduced. Captain Galton in his third paper (Proc. Inst. M. E., April, 1879, page 172) states that "the coefficient of friction between the brake blocks and wheels varied inversely, according to the speed of the train." This must not be taken to mean in inverse ratio, but simply that the friction increased as the velocity was diminishing. For instance, in one case with cast-iron brake blocks and steel tires, with velocities of 60, 40, 20, and 10 miles an hour, the corresponding coefficients of friction were ·074, ·140, ·192, and ·242. Another remarkable fact was made evident, which was that the coefficient of friction was affected by the duration of the time of application of the brakes. Thus, when the speed of the van from which experiments were made was kept constant by the engine, instead of allowing the resistance to bring it to rest, "the friction of the blocks *decreased*, and this occurred notwithstanding a continued increase of the brake-block pressure, showing that, through some cause not yet fully determined, the holding power of the brake blocks at all speeds is considerably less after some seconds of application than when first applied." The result of this is that "the decrease in the coefficient of friction arising from time to time, sometimes overcomes the increase in the coefficient of friction arising from a decrease in speed." This is especially so when the train takes some time in coming to rest, in which case a higher brake pressure is required. Prof. Kennedy, in his "Report on Friction at High Velocities" (Proc. Inst. M. E., Nov., 1883), has plotted Captain Galton's results in order to see if the difference between the frictional resistances at different speeds would still remain after those resistances had taken the lowest value to which they tend, and which they must certainly reach (although not, perhaps, in the limited time of 30 seconds, for which each experiment usually lasted), and the result of the plotting shows that, "so far as can be judged, the difference would remain." The effect of increase of velocity with lubricants seems in every case, after a certain point is reached, to produce a corresponding increase in friction. Thus from an examination of the seven tables of results obtained by Mr. Tower (Proc. Inst. M. E., Nov., 1883, page 643-650), it is seen that in all cases where a bath of lubricant was used the friction increased as the speed was increased from 100 revolutions (corresponding to 105ft. per minute) up to 450 revolutions (corresponding to 471ft. per minute). But though increasing as the velocity increases, it does not do so as rapidly as the square of the velocity, which would be the case, or nearly the case, if the laws of fluid friction maintained. Professor Thurston considers that for cool journals, lubricated with good sperm oil, and between the limits of 100ft. and 1,200ft. a minute, the friction may be represented approximately by the expression $f = a\sqrt[5]{V}$ where V = the velocity, and for a pressure of 200lb., a = ·0015. For cases where the lubrication was effected by an oil pad or by a siphon lubricator, Mr. Tower found that the friction decreased up to a certain point and then increased. For perfect lubrication, that is with an oil bath, the speed of minimum friction was found to be from 100ft. to 150ft. per minute; but this point tended to rise with increase of load and with less perfect lubrication. It is an interesting fact that all the plotted curves of Professor Thurston's latest results, representing a very large number of experiments, all show this preliminary decrease (often rapid) with velocity, and final increase after a certain velocity is reached. This being so, the above formula cannot hold, at any rate, below that point.

IV.—*The effect of change of temperature.*—Scarcely anything seems to be acccurately known with regard to the effect of different temperatures on the friction of solids. With regard to the effect in the case of lubricants, much recent experimental work, by different observers, has been published; but the results are so varied, not to say contradictory, as to make it extremely hard to generalise upon them. Mr. Tower found that, in his experiments with a bath of lard oil, as the temperature, rose from 60° to 120° F. the friction was in every case diminished. Thus for 105ft. per minute it was ·0059 at 60°, ·0048 at 70°, ·0040 at 80°, ·0034 at 90°, ·0029 at 100°, ·0026 at 110°, and ·0024 at 120°. Mr. Woodbury has quite recently published the result of more than 1,000 observations on a standard brand of mineral oil. The flash test of this oil gave 342° F., the fire test 410° F., evaporation at 140° F. for 12 hours was ·02, sp. gr. ·888. The velocity was maintained constant at 300ft. per minute. By increasing the pressures uniformly from 1lb. to 40lb. per square inch, it was found that the coefficient of friction decreased in a remarkably uniform manner as the temperature increased. Professor Thurston has made a large number of experiments on this subject. In one set of experiments in which sperm oil was used, at constant velocity of only 30ft. a minute, he found the friction *increased* with the temperature: at 200lb. per square inch the friction rose from ·0056 at 90° F. to ·05 at 150°, an increase of nearly ten times for a rise of 60°. At 100ft. per minute, and for pressure below 50lb. per square inch, he found that the friction did not vary between 90° and 150°, but that it rose nearly 300 per cent. at a pressure of 200lb., over 100 per cent. at 150lb., and 33 per cent. at 100lb. The latest experimental results by this observer, and others, show the laws which connect friction and temperature to be of a most complex nature. There have been various attempts to express them in a simple form, as, for instance, by Prof. Franke (quoted by Prof. Cotterill, "Applied Mechanics," page 258) in the formula $f = f_o e^{-av}$, where f_o = ·29; a (for velocities of one mètre per second) ranges from ·02 to ·04, v representing the velocity. But in view of the nature of a large number of results such attempts do not seem satisfactory.

The Friction of Higher Pairing or Rolling.

The laws of rolling friction, as given by Coulomb, have been already stated in a concise form, purposely placed in juxtaposition to the corresponding statement of the laws of sliding friction, in order to show their remarkable similarity. The only difference between them lies in the fact that in the former the resistance varies, as might be expected, inversely as the radius of the rolling body, so that comparing rolling bodies of the same radius, but otherwise under different conditions of material, pressure, and velocity, the laws are the same. Such a fact might have suggested that the retarding causes at work in the two cases were the same; but this does not appear to have been recognised, resort being had by Tredgold and others to the artificial idea of a couple with a length of arm depending on the nature of the surfaces. To Prof. Osborne Reynolds is due the first satisfactory explanation of resistance to rolling, in a paper in which it is conclusively proved to be the direct result of sliding friction. Professor Reynolds first investigates the deformation produced at the point of contact, and proves that this must result in a *sliding* of one surface over the other; that this takes place both in contraction—that is, both as the wheel or roller is approaching any particular point in the surface and leaving it; that consequently the amount of friction depends not merely on the roughness of the surfaces in contact, but also on their softness, or the extent to which they yield. These two effects tend to counteract each other, a greater frictional resistance allowing less extension of the surfaces, and a greater extension resulting from a small coefficient. Since, however, the work of friction is the product of the resisting force into the space passed through or rubbed over, it is evident that when the coefficient is zero, or there is *no resistance*, and when it is such that the surfaces are locked together and there is *no slipping*—that is, at the two extreme values of the coefficient of friction—there is no work at all done. Therefore there must be some intermediate value of the coefficient of friction for which the work done in overcoming friction is a maximum. Prof. Reynolds experimented on surfaces of various kinds, in several sets of observations. A very accurately prepared cast-iron roller was placed successively on surfaces of cast iron, brass, plate glass, boxwood, and indiarubber, which was tried, both clean, and oiled or blackleaded. The resistance was estimated by inclining the lower surface until the roller just started into motion, the amount of the inclination being obtained by means of a surveyor's level, placed upon the surface, and used to take initial and final observations from a staff placed 50ft. away. The results of these experiments showed that the resistance to motion on the metallic surfaces of cast-iron, brass, and glass was much the same, though rather less on the first of these in starting, and rather greater in rolling back. The boxwood surface caused about twice the resistance of the metals, indiarubber about six times in starting, and ten times in rolling back. The results of oiling or blackleading the surfaces were curious, and, to a certain extent, in accordance with what might have been expected, for on the harder surfaces, in starting from rest, the effect is to reduce the resistance, whilst on indiarubber the effect is to increase it. On rolling back, however, the result in the latter case is reversed, and the friction is less with the prepared surface than with the clean one, though greater in the case of glass and brass. Some other experiments were made upon the actual slipping on a hard cast-iron roller on an indiarubber surface, and of a soft indiarubber tire on a hard surface, which proved that a hard roller on a soft surface rolls short of its geometrical distance, but a soft roller on a hard surface rolls more than its geometrical distance, though to a less degree, and, finally, that a roller on an equally hard surface rolls less than its geometrical distance.

The above results quite accord with the views set forth in the paper in question, as to the nature of rolling friction, and the writer remarks that the surprising durability of steel rails is accounted for, not directly by reason of their greater hardness compared with iron, but by reason of the fact that the greater hardness reduces the slipping, and thus the rolling friction; the same reasoning goes to account for the fact that the harder rails wear at all, which could not be done on the mere hypothesis of a pure rolling motion.

An important case in which rolling and sliding friction can be directly compared occurs in the case of the brakes of railway trains, and the experiments of Captain Galton and Mr. Westinghouse, already referred to, led to the interesting discovery that the retarding effect of a wheel sliding upon a rail was much less than when braked with a force of just sufficient magnitude to allow it to continue to revolve. The calculations from these experiments showed that the friction between the wheel and the rail when the wheel is sliding on the rail is *less than one-third* of the friction between the wheel and brake blocks when the wheel just continues revolving. This result appears to be due to the simple fact that the rolling friction was greater than the sliding friction, and, in fact, in the case of a steel tire on a steel rail no less than three times as great. The comparison of sliding and rolling friction, and their relation to each other, is a subject of very great importance, and the author is at present engaged in making some experiments which promise to throw further light on the matter. The subject of rolling friction demands greater attention from engineers, for, notwithstanding its many important practical applications, it is as yet but little understood, and in one application alone—viz., that of friction-gearing—it may be that a more careful study of the conditions of the problem will, in the future, lead to its greatly extended use.

The author, in conclusion, must confess how imperfect he feels the foregoing sketch of our knowledge of friction to be. If, however, he has succeeded in calling attention to some of the main features of recent advance in the scientific treatment of the question, this paper will not have been written in vain.

* A paper read before the Liverpool Engineering Society.

IN the September number of the *Meteorologische Zeitschrift*, Prof. Hann gives the results of many years' observations on the temperatures of the various parts of the Vienna forest. The forest valleys have a considerably lower temperature than the open land outside. This difference is smallest in winter and greatest in summer. But there is no similar effect during the course of the day, for the afternoon difference is not the greatest. It is actually least in the warmest hours of the day, and greatest in the cooler part. In the early morning and evening the influence of the forest in lowering the temperature of the air is greatest.

A PAPER on comparative study of the actions of walking and running, together with the mechanism of the transition between these two movements, was recently read before the Paris Academy of Sciences, by MM. Marey and Demeny. In this paper, which complements the author's previous communications on animal kinematics, numerous differences are shown to exist between slow and rapid pace, the latter being characterised by moments of complete detachment from the ground and by other equally important features scarcely visible to the naked eye; but which are now clearly revealed by the chronophotographic and dynamographic processes. The paper was furnished with six diagrams illustrating the contrasts between both motions and the transitions from one to the other.

THE statue of Liberty on Bedloe's Island, New York Bay, when completed, will be illuminated at night in a novel manner. The torch held by the statue will contain eight electric lamps, of 6,000 candle-power each, the light from which will be thrown directly upwards, making a powerful beam and cloud illumination. Four or eight lamps, of 6,000 candle-power each, will reflect their light upon the statue, illuminating it and causing it to shine forth in bright relief.

SCIENTIFIC NEWS.

MANY old students will hear with great regret of the death of Frederick Guthrie, Ph.D., F.R.S., Professor of Physics, Normal School of Science and Royal School of Mines. Prof. Guthrie died on the 21st inst. at the comparatively early age of 53 years.

Dr. Alexander Dyce-Davidson, Professor of Materia Medica in Aberdeen University, died suddenly in his class-room in Marischall College one day last week. The bursting of a blood-vessel in the head was the cause of death. The deceased, who was a native of Aberdeen, was 41 years of age. He graduated M.A. at Aberdeen University in 1863, and M.D. three years later. He was appointed Professor of Materia Medica in 1878.

Dr. J. von Hepperger, of Vienna, has published "Elements of Comet Barnard" (1886*f*.), which differ from those given on p. 170, calculated by Mr. Ritchie, jr. Dr. Hepperger makes the time of perihelion passage Dec. 24·3064 Berlin M.T.; $\pi - \Omega$ 78° 56′ 20″; Ω 140° 17′ 55″; i 93° 33′ 52″—mean equinox 1886; log. q 9·61236. About the time this will reach the majority of our readers, the comet will be near Nu Virginis.

In a communication to the Paris Academy of Sciences M. Cruls, director of the observatory of Rio de Janeiro, says that the transference is about to be commenced, the new site being on the same parallel, but two minutes further west. The Brazilian Observatory has an advantage over all others, as for forty days in the year the sun's zenith distance does not exceed one degree. M. Cruls will endeavour in the new building to make regular observations of terrestrial magnetism and atmospheric electricity.

Some experiments lately brought before the Paris Academy of Sciences by M. Luvini, combine with those of other observers, he considers, in warranting the conclusion that "gases and vapours, under any pressure, and at all temperatures, are perfect insulators, and cannot be electrified through friction, either with one another, or with solid or liquid substances."

Mr. Jarman has fitted up in the garden of 443, Brixton-road, S.W., a tram-road, on which he runs a model self-contained electric tram-car driven by his patented electromotor. This motor is of the Pacinotti type; but its most novel feature is that the axle carries two armatures, one of which is used for driving in one direction, and the other for propelling the car in the opposite direction. The current being cut out of the field on one side, that armature, rotating in the air, has time to cool down if it should have become heated, and it is considered that the extra cost of the, so to speak, spare armature and fields is amply compensated for by the fact that the arrangement avoids all risk of damage from excessive heating. The full-sized car, which Mr. Jarman intends shortly to build, will carry E.P.S. cells under the seats, and each car will have two or more sets, so that on its arrival at the terminus or at the charging station the cells can be drawn out on to a trolly, and be replaced by a set which has been undergoing the operation of charging. The time occupied in effecting that change certainly need not be longer than is now necessary with the horse-traction. The weight of the mechanism, including sixty storage cells, will be only two and a half tons for a 46-seat car. The model exhibited weighs about 168lb., and readily turned three curves of 6ft. radius, one at least on a rising gradient. The motor is reversed by a simple lever, and the car is always under complete control.

A method of making fine filaments for incandescent lamps is somewhat analogous to wire-drawing. Mr. R. Dick, of Glasgow, prepares the fibre of the *Caryota urens*, known as Kitool fibre, and imported from Ceylon for brush-making, by drawing it to a uniform size through sharp dies. The fibres are then placed in fine copper tubes, much shorter than the Kitool, and the whole passed through a draw-plate, which has the effect of squeezing the metal round the fibre, and compressing the latter. The tubes and filaments are then cut into lengths, and placed in a crucible, where the filaments are carbonised, and the copper is subsequently dissolved off by means of acid, portions being left to form connections.

It is stated in a French paper that Prof. Place, of the Cavalry School of Saumur, has recently applied electricity with great success to horses which prove refractory while being shod. A vicious beast will often give much trouble in shoeing. M. Place's method renders it at once tractable, and permanently cures its aversion to the forge. An electric shock is given through a bridle of special form.

A new alloy of nickel, which is said to possess a specific electrical resistance much higher than that of German silver, is reported to have been discovered at the Munich Electrical Laboratory.

It is proposed to hold a Tercentary Potato Exhibition at the beginning of December in St. Stephen's Hall, Westminster. It will not be merely an exhibition of potatoes, but will consist of four sections, containing: (1) an historic and scientific collection, including early botanical works in which the potato is figured, and papers, &c., in which attempts have been made to define the different species; (2) illustrations of the potato disease; (3) methods of storing, preserving, and utilising partly diseased potatoes; and (4) a display of all the varieties of potato now grown, with labels giving date of planting, locality, nature of soil, &c.

M. Rucktchell, a Russian engineer, has invented a new explosive, which he calls "silotvaar," with which experiments have been recently carried out at the camp of Krasnoie Selo, near St. Petersburg. As compared with ordinary gunpowder, the penetrative power of the new explosive, when used for cartridges, is stated to be ten times greater. The explosive emits neither smoke nor heat, and the discharge is unaccompanied by any report. Since these experiments the Russian war and naval authorities have had the new explosive examined and tested by experts, who are stated to have reported favourably upon it. It is further stated that a motive force may be generated with the explosive by means of an engine constructed by the inventor, for which he claims superiority over steam and gas-engines. The inventor has patented both the explosive and the engine in several countries.

M. A. Verneuil brought before the Academy of Sciences of Paris at a late meeting a paper "On the Preparation of the Sulphuret of Calcium with Violet Posphorescence," on the principle laid down by M. E. Becquerel in his researches on phosphorescence. M. Verneuil has succeeded in effecting the synthesis of this substance, which has long been known in commerce, but the preparation of which has remained a secret.

USEFUL AND SCIENTIFIC NOTES.

A SUCCESSFUL and interesting narrow-gauge railway has been constructed by W. G. Bagnall, Castle Engine Works, Stafford, at Spezia, to ascend the Monte Cappuccini. The distance from the quay to the summit is about three kilomètres. The railway winds to the top with a succession of heavy gradients, several being 7·1 per cent., and sharp curves from 34ft. radius upwards. The gauge is 80cm. (31½in.). The engines, which have 10in. cylinders, make twenty journeys a day, and take six wagons containing 2½ tons of stone each. Mr. Bagnall says the idea was ridiculed by the engineers there, but the saving had proved to be fully 60 per cent.

THE Guarantee Committee of the Universal Exhibition of 1889 was formally installed in Paris last week. M. Lockroy, Minister of Commerce, who was present at the inaugural meeting, thanked members for subscribing to the Guarantee Fund, and said that their patriotism had succeeded in surmounting the difficulties of furnishing the necessary capital, which has now exceeded twenty-two million francs. The Minister called upon the Committee to hasten its labours, as the various factories were awaiting orders. "Throughout France," added M. Lockroy, "industry was preparing for the great struggle, and for a pacific victory which would restore to France her position in the world."

A REPORT just published by Dr. Eck shows that the average death-rate in European Russia is 68 per cent. higher than in England. This means that, roughly speaking, three Englishmen live as long as five Russians.

LETTERS TO THE EDITOR.

[*We do not hold ourselves responsible for the opinions of our correspondents. The editor respectfully requests that all communications should be drawn up as briefly as possible.*]

All communications should be addressed to the EDITOR *of he* ENGLISH MECHANIC, *332, Strand, W.C.*

All Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks, a vice from whence great inconveniences derive their original."—*Montaigne's Essays.*

ABNORMAL TELESCOPIC DEFINITION.

[26413.]—MR. FRANKS'S "Notes on Telescopic Definition as affected by the Direction of the Wind" (ENG. MECH. Vol. XLIV. p. 61) are of great interest. The *locus classicus* on the triangularity of the star discs is, of course, Dawes's preface to his observations in Vol. XXXV. of the *Memoirs* of the R.A.S. Mr. Franks seems to imply that the phenomenon was noticed by Sir W. Herschel, and I have no doubt he is right; but I must confess that I have not myself been able to find any passage in Sir William's printed observations or MSS. relating to the matter. I do not know whether it has been noticed in Asia; but it has been observed in all parts of Europe, from Dublin to Pulkova, and from Upsala to Naples. I think (but I speak from recollection merely) that on mentioning the matter to Mr. Burnham and Dr. Gould, the former said he had not seen anything of the kind at Chicago, nor had the latter at Cordoba. As Dawes remarks, its association with the east wind seems unaccountable. I have, however, seldom seen it with reflectors, when a refractor, at the same time, exhibited it in a very marked manner, and a somewhat analogous phenomenon has often been observed with the 26in. at Washington, though I am not aware that the discs have ever been noted to be triangular there. Prof. Hall writes: "I would be observing stars near the zenith, the images being tolerably good; on turning the telescope down towards the north to the star Σ 2034 [+ 83° 59′ north decl.], the images at first would be fair; but after a few minutes, and before an observation could be made, the images would become so bad that an observation was impossible, the stars being simply a confused mass of light. This condition was probably produced by the cool north wind blowing against the warm object-glass and disturbing its figure. Our large objective is very sensitive to change of temperature, and will not perform well so long as these changes are rapid." Dembowski, as might be expected from the enormous number of double-star observations made by that prince of observers (he made at least seven times more measures than our own Dawes, or as many as Struve's and O. Struve's combined) has many notes on the triangularity of star discs. I give the following observations of his:—

1862, July 29. 70 Ophiuchi = Σ 2272: "Osservato coll'oculare 670, vidi un singolare fenomeno ottico. Le due stelline apparivano triangolari, anzi erano due perfetti triangoli equilateri, colla base all' incirca parallela all' orizzonte, ed il vertice opposto alla stessa, rivolto verso lo Zenit. In quel momento l'aria era tranquillissima, ed il massimo ingrandimento 670 reggeva perfettamente. Gli annelli attorno ai due dischette, invece di essere circolari e continui, erano rotti in tre pezzi, rappresentati da tre piccole linee rette, decrescenti in lunghezza ed in intensità e parallele ai tre lati del triangolo. Sostituiti gli oculari 500 e 400 l'effetto rimase lo stesso. Dopo una quindicina di minuti circa le due stelline ripresero la loro forma rotonda. Non ho mai veduto nulla di simile. Questa è l'immagine in vertita dell' apparenza che presentavano." [Cf figure 1.]

1862, July 30. η Cassiopeiæ = Σ 60: "Oculare 500. A 22h. 40m. in un momento di tranquillitá perfetta, si reproduce il fenomeno di jeri, cioè delle stelle in forma di triangolo. *A* specialmente era un perfetto equilatero. Dopo un pajo di minuti l'apparenza svani et ridivennero del tutto rotonde."

1875, August 18. η Cassiopeiæ = Σ 60. "All' oriente 19h. 43m. aria buona. *A* va facendosi in triangolo confino a cinque pezzi d'anello [cf. figure 2] decrescenti in intensità e lunghezza, e paralleli ai tre lati del triangolo. La base è sensibilmente parallela all' orizzonte. *B* invece non presenta traccia alcuna di forma triangolare. Essa è, o *sembra*, perfettamante rotonda."

I have selected these observations of De's on

account of their very curious characters. The short duration of the phenomenon, and, in the case of the observation of August 18, 1875, the extraordinary fact that one star only of the pair was affected (the distance as measured by De that night was 5·64″), render these some of the most remarkable cases on record. Several other curious phenomena, not adverted to by Mr. Franks, have been noticed from time to time.

There is only space at present to say a few words about two of the most remarkable, viz., transient cases of spurious duplicity, and the absence of diffraction rays. My late regretted friend, the Rev. T. W. Webb, has given so excellent an account of the first that it will be advisable to quote it in full from the *Intellectual Observer*, Vol. IV. p. 194. "The evening of July 27, 1863, had been cloudless, but hazy, with flaring and fluttering definition. As night advanced, however, it improved, and towards 11h. the discs of the stars came out finely: about this time, in endeavouring to meet with the beautiful triple star ε Equulei . . . I came across a 6-mag. star with a close 8 or 8½ mag. companion, about 1·5″ and 330°, both discs being very nicely defined. Thinking that this might be an object of W. Struve's, which I believed to exist in that quarter, but had never seen, I looked carefully at it, and continued my search, turning to a similar star in the field of the finder, some 2° distant. To my great surprise this had the same appearance. I tried a third; they were all alike. I at once turned the eyepiece (an achromatic combination, by Powell and Lealand, giving a power of about 300) round its axis; but the images remained unchanged. I then turned the object-glass one-third round; the companion was still there—I fancied

FIG. 1

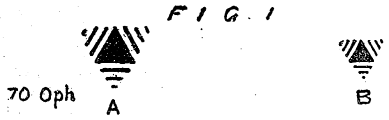

FIG. 2.

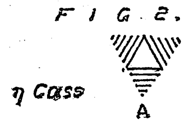

FIG. 3.

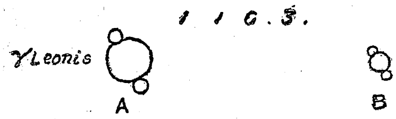
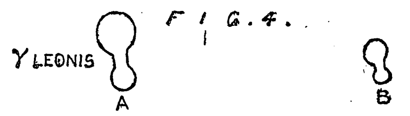


at first somewhat altered in angle, but further examination proved that I was mistaken; and a turn of another third made no difference. A star not far from Al Tair gave the same result, perhaps less distinct. I looked to the west towards Hercules; still something of the same kind came before me, though not so clearly. I returned to my first three stars; in each case the attendant was still perceptible, though much less obvious, and apparently fading away: while occupied among them I came unexpectedly across my intended object, ε Equulei; and here the beautiful and black division of the close pair at once satisfied me that neither the eye nor the instrument could be the cause of this singular deception. I regretted that its short continuance, and my own haste, prevented me from testing it more fully on other stars, and with other eyepieces, but as to what I did see, no doubt remained. During an experience of many years I cannot remember a similar illusion, excepting perhaps once, with a single star, and even that may be questionable. It may possibly be referred to some unusual condition of atmosphere, producing, apparently, for a short time, something like double refraction in a vertical plane. Similar effects, it is well known, are frequently perceptible in looking at distant shores or vessels across a considerable intervening surface of water—a species of *mirage*, of which I was a frequent spectator at Clevedon during the summer of 1846, especially in using a little hand-telescope." I have seen this singular phenomenon once very distinctly, and only once—viz., on February 19, 1874, in bright moonlight, with a 3in. refractor. Stars in the S.E. only were affected, 8 Monocerotis having a spurious *comes* at 140°: 2·5″, 8½ mag., ε Hydræ being triple, with a spurious disc at 165°: 3·5″; but γ Ceti was only seen double, and single stars in the north were unaffected. The illusion lasted about 20 minutes. I had the pleasure of seeing Mr. Hunt a few days ago, and I asked him, in the course of conversation, if he had ever noticed anything of the kind with his beautiful 8in. o.g., which formerly belonged to Dawes. I think he said that he had not; but he believed he had very distinctly on one occasion with a small transit instrument, but only in the case of one star.

Dembowski has several observations of this optical deception. He writes in his observing book on May 30, 1863, not two months previous to Webb's observation:—"Σ 1424 = γ Leonis. Oggi questa coppia mi ha presentato un aspetto singolarissimo. L'aria era tranquillisima, ma fosca. Vi era come una annebbiatura generale, che dava all' aria una tinta grigio—azzurra. Osservato prima e dopo il tramonte del sole, oculare 400. Nel principio le due stelle apparivano come due dischetti minuti, ma di luce intensa, e circondati da un annello completissimo e di luce perfettamente stabile. Lo spazio fra il dischetto e l'anello poteva dirsi *nero* ed era abbastanza ampio. Talvolta l'anello si sformava, e subentrava quest' altra configurazione [cf. figure 3] li due dischi fittizi rappresentanti le due stelle erano accompagnati ciascuno da altri due dischetti più piccoli, l'uno sopra, l'altro sotto, ma tangenti ai primi. Diametralmente opposti l'uno all'altro, la loro congiungente faceva all' orrizzonte un angolo di circa 60°. Tal altra volta offrivano questo altro aspetto [cf. figure 4], in luogo di quattro dis-

FIG. 4.



chetti secondarî tangenti, vi erano solamente due dischetti secondarî più piccoli dei principali, ed attacati ai medesimi mediante due tratti luminosi. In tutti i casi il fenomeno era stazionario per qualche tempo. Rammento d'aver osservato qualche cosa di simile a Napoli, se non erro sopra ζ Aquarii [Yes, on Dec. 10th, 1857]. Mano mano che si avanzava il crepuscolo le stelle crescevano in luce, le diverse configurazioni perdevano di precisione, e succedeva un rimescolamento. Poco dopo osservai ξ Ursæ Majoris. Continuano anche su questa copia le apparenze vedute in γ Leonis, ma sono molto rare le due seconde, e per lo più ha luogo la prima, cioè quella dell' anello completo. Provato dopo la misura di 35 Comæ, non posso farne nulla: la persistenza dell' anello che passa sulla compagna (distante 1·3″) toglie ogni possibilità di misura." And again on May 17, 1870, when observing Σ 1722, Comæ 179, a pair of 7·7 and 8·7 mags. 3·1″ apart, he writes:—"Talvolta si vedono altri due dischetti precedenti ai veri, alla distanza di circa 1″. Dopo pochi minuti scompajono del tutto, e restano solo le vere immagini."

The temporary absence of rings is mentioned by Webb on p. 3 of the fourth edition of "Celestial Objects," and is a rather inexplicable phenomenon. Sir J. Herschel writes of it thus:—"December 31, 1830, ξ Ursæ Majoris. Perfect measures. No appendages, and scarcely a trace of rings about the stars, which are like two pearls, and perfectly motionless; really, I never saw anything like it." "ξ Boötis. March 29, 1830. (The finest of the fine nights of last spring.) The observation says; 'In my life I never beheld anything so lovely. There is a sort of liquid light in it; a soft, quiet lambency in the discs such as I never before witnessed (and only once since—viz., on Dec. 31, 1830). *The rings are but traces of rings*—all their light being absorbed into the discs.' The very remarkable fact in this last sentence, corroborated by the observation of ξ Ursæ on the 31st December, and illustrated by a diagram made of it at the time, is so prominent a feature in the optical history of these rings and the general subject of the action of telescopes, that I could not but insert this remark at length." Sir John was using the 5in. equatorial. I have given a remarkable observation of De's of the absence of rings in the case of O Σ 159 on page 21 of the "Corrections," &c., to Gledhill, Crossley, and Wilson's "Handbook of Double Stars." He calls it "momento sublime!" as it must have been, the bright yellow disc of the larger star of the very close pair O Σ 159 appearing to cover about a quarter of that of the blue disc of the small star, there being not the slightest trace of a diffraction ring to either star. He saw it again in 1870 and 1876. Can "A Fellow of the R.A.S." or Mr. Knott (whom I thank for his kindness and trouble in observing the planetary nebula H IV. 37) give me any information as to where the investigation of the "eminent German astronomer," mentioned by Prof. Wheatstone to Dawes (*Memoirs* R.A.S., Vol. XXXV. p. 156), is to be found? I have searched for anything of the sort in vain. It is certainly not in anything published by Bessel; but there are a good many "eminent German astronomers."

October 16. **H. Sadler.**

DOUBLE STARS—α LYRÆ—θ AURIGÆ—δ CYGNI—41 ARIETIS.

[26414.]—On the night of Oct. 11, while observing various stars, I turned the glass (a 4in., by Cooke) upon α Lyræ, having a desire to see if the companion could be seen in full moonlight; the distance I had some recollection of being about 40″ to 50″, but the position angle had been entirely forgotten. Putting on a diagonal eyepiece, I ran my eye around the star for some time, and finally suspected a point at one position. A short watch nearly convinced me that it was the companion; but to satisfy myself more fully, I revolved the diagonal with my eyes shut, and then ran around the star again.

In a few moments the point was again seen, but in a different position in the diagonal. Keeping my eye upon the smaller star, I turned the diagonal back to its original position, and found the point of light came back to where I had first seen it.

The diagonal was then taken off, a direct eyepiece put on, and in a few moments the companion was again picked up, and its position angle estimated. Upon referring to Webb, I found it agreed pretty closely, so that I felt sure it was seen. While looking for the close companion another more distant one was seen almost pretty steadily after once noticing it. Its position was *n.f.*, and about three times as far distant as the close companion. Upon referring to the diagram of Mr. Sadler, on page 10, I find it was the star marked there as B, but it was easier than the close companion, and was first noticed without thinking of it. In Gore's "Catalogue of Suspected Variables" this star is spoken of as being a magnitude fainter than the well-known companion in Oct., 1870. It certainly seemed to me brighter than the close companion on Oct. 11, as it was noticed without even looking for it. On the same night at 11h. 40m. I used a p. 200 upon θ Aurigæ, and a small star estimated at about 10th magnitude was seen pretty steadily, at about 35″ *n.p.*, position about 300° The close companion mentioned in Webb I could not see, although carefully looked for; neither could I do anything with δ Cygni, although the moon was within a day of full. The star 41 Arietis is given by Mr. Sadler in his "Star Guide" as a space-penetrating test for a 4in. glass. On Sept. 2, while trying to remedy a slight tilt in the o.g., I turned it upon this star accidentally, without knowing its name, and after some little attention saw two faint companions. Not finding the star in Webb, I made a careful estimate of distance and position, and after coming down from my observatory referred to Mr. Sadler's work, where I found that my estimates agreed with his measures very well. Both companions, however, were picked up without knowing it was a double star, and while casually turning the glass upon various stars to see their discs and rings. **Ariel.**

THE BRANDENBURG LUCKY STAR.

[26415.]—The above, which only appears at intervals of three centuries, is expected within the next four years by Continental astronomers. The star was so called because it appeared the night the Elector Johann Sigismund of Brandenburg was born. It was first noticed, however, in 945, during the reign of Emperor Otto I., shining in the constellation Cassiopeia, and then vanished until 1254. Tycho de Brahe suddenly discovered the star in November, 1572, sparkling with greater brilliancy than any star of the first magnitude, and nearly rivalling Venus. It could be seen even in the daytime, and shone distinctly through the clouds at night when all other stars were invisible. The light soon began to fade, and the star finally disappeared in 1574, after being visible for seventeen months.

The time for its reappearance is thus now at hand. (Above is a copy of a paragraph from the *Graphic*, Oct. 16, and may interest.) **D. A.**

SUNSET PHENOMENA—EARTHSHINE.

[26416.]—The pink or salmon-coloured "streamers" of "E. E. M." (letter 26390, p. 171) are merely the sunlit intervals between wider cloud shadows, cast through the air by some clouds just out of sight beyond his west horizon. The appearance is common enough within the Tropics, and I once saw at sea, near Barbadoes, a double daily display, each morning and evening, for nearly a week. On one morning this had the comparatively rare feature that the beams were traceable all across the sky, so as to grow *convergent* to the west, and plainer there than overhead. It may seem a puzzle that perspective can make the sun's really diverging beams appear to *converge*; but we must remember that all of them visible to us, in our few score leagues of atmosphere, are practically quite as *parallel* as the lines of any building. Like the cornices of a gallery, they will converge whichever way we look, to the sun or from him. Brewster's "Optics" mentions these "converging beams," which I have once, too, seen in Europe.

"F.R.A.S.," on the same page (171), says "the earth-illumined part of the moon's disc is rather brighter before the new moon" (i.e., in the mornings) "than after it" (in the evenings), but does not point out how well this accords with theory. When we (in Western Europe) have the moon rising, the terrestrial hemisphere turned to her contains all the old continents; but when we have her setting, the earth turns chiefly oceans to her,

reflecting far less light than the lands. This inferiority of earthshine on the setting new moon, compared to the rising old one, must be true of all places in the Atlantic and both American continents. But the contrary should be observed over all Eastern Asia, Australia, and the Pacific Islands. Their setting moon must get more earthshine than their rising one. **E. L. G.**

EGYPTOLOGY.

[26417.]—MAY I contribute a little to the question of Israel's captivity in Egypt?

"Now the sojourning of the children of Israel, who dwelt in Egypt, was four hundred and thirty years." (Ex. xii. 40.)

"The Covenant, that was confirmed before of God in Christ, the Law, which was four hundred and thirty years after, cannot disannul." (Gal. iii. 17.)

This number is twice mentioned (Gen. xv. 13; Acts vii. 6) indefinitely, because definiteness was not required.

There is a difficulty connected with these Scriptures, for, notwithstanding the assertion that the Children of Israel were in Egypt 430 years, they were really there, in our reckoning, only 215 years, just one-half the time. Consider the following table:—

	Years.
Abraham, after the Covenant, to the birth of Isaac	25
Isaac, to the birth of Jacob	60
Jacob, when he went down into Egypt	130
	215

When was the Covenant made? When Abraham was 75, just before he went down into Egypt (See Genesis xii. 4). From this period God reckons the whole period of 480 years, which close with the exodus of the host of Israel. Israel were the seed of Abraham (Consult Heb. vii. 5—10). God made the covenant with Abraham by word at first (Gen. xii.); afterwards by oath (Gen. xv. 9, &c.; Heb. vi. 17).

Clifton. **W. Howell.**

[26418.]—"RAMASES" is mistaken (26323) in supposing I wish to exclude the testimony of the Bible. I admit its value, as I would that of any other ancient book, but do not look on its historic or scientific statements as final. We have only it to prove that the Israelites were in Egypt, which I do not deny, though I doubt the details of the story. As "Ramases" admits the records are "more or less imperfect," it seems to be the amount of error, not the general principle, on which we differ.

As to Gesenius, I have no library at command, and cannot refer to his works; but, knowing that he changed his earlier rationalistic views in later life, I do not attach much weight to his opinion (probably an early one) on the nature of a generation. Why does not "Ramases" give the facts on which Gesenius relied? We are not children—we want facts, not opinions, and Gesenius had no secret information. "Ramases" seems oblivious of the prevalence of Herbert Spencer's philosophy and of agnosticism when he says Strauss's influence is on its last legs. I consider it was never so widespread or so strong.

The "about" of Fairbairn's "Biblical Dictionary is not of much value, as the revisers omit it altogether.

The main defence offered by "Ramases" is that of traditions of the Apostolic age; though, in reality, these may only have had reference to some general statements of Moses, especially referring to the Commandments, and not to the form or verbal peculiarities of the old books.

The writers of the New Testament used words often in a poetic and non-scientific manner, as the passage Acts ii. 5 proves e.g.:—"And there were dwelling at Jerusalem Jews, devout men, out of every nation under Heaven." Will Ramases claim that Jews were there from Mexico or Peru? And if not, why not, if the writings are accurate?

Late traditions respecting ancient history or writings are not trustworthy, and are apt to be produced to suit circumstances, and the objections against the Mosaic authorship of the Pentateuch are so many and so weighty that tradition is worthless against them. I will state a very few objections.

1. Moses is said to have been learned in all the learning of the Egyptians, and therefore knew something of their history, so could not have placed the Deluge at the date we find it in the Hebrew Bible—according to that, it occurred B.C. 2288; but, as Menes, the first king of the first regular dynasty lived at least 1,000 years before that date, it seems as if no one versed in Egyptian lore could make any such statement. The Egyptians claimed an immense antiquity; but the labours of the learned have cleared the mystery up to a very great extent, and Mr. Sayce, in his "Ancient Empires of the East," says, at page 23:—"The date to which this event (the time of Menes) was assigned by Manetho has, for reasons already given, been variously computed. Boeckh makes it B.C. 5702; Unger, 5,613; Mariette, 5004; Brugsch, 4455; Lauth, 4157; Pessl, 3917; Lepsius, 3892, and Bunsen, 3623. We shall provisionally adopt the dates of Mariette, whose long-continued excavations in Egypt have given him an exceptional authority to speak on the matter."

According to the Septuagint (written in Egypt, and very late) the date of the Deluge is 3216 B.C.—not far from Bunsen's date for Menes; but as the oldest remains in Egypt give proof that the civilisation was old and very peculiar when they were made, it is idle to suppose that any of the dates of the Flood could have been written by one versed in Egyptian knowledge. This seems to me to prove that Moses did not write Genesis.

2. Moses must have known all about the immortality of the soul; yet no mention is made of it in the Law. In Egypt it was the main thought and hope of the people, and yet amongst the Hebrews no reference seems to be made to it; the point referred to by "Ramases" being very doubtful at best. The Hebrews appear to have been all Sadducees, and this could hardly be so if one brought up as an Egyptian had written the Law, and believed in immortality.

3. Three separate Pharaohs are mentioned in the Bible; but no special name is given to any of them. If Moses knew personally the two last, it seems wholly unlikely he would not specify them personally, especially as multitudes of details of other things are given. To use the word "Pharaoh" as a generic term would be natural to a late writer, but not to a contemporary, when three different persons are referred to.

4. It is not usual for a writer to record his own death and burial; but if Moses wrote the whole of the Pentateuch, he must have done so. That fact would not be taken by any court of law to be other than a proof that the person spoken of as dead and buried *did not* write the passage. But if the book is examined, it will be found that the style of the writer of the passage is that of a large part of the whole.

5. Numerous passages occur which prove late authorship, such as the following:—Gen. xxxviii. 31, "These are kings that reigned in the land of Edom, before there *reigned any king* over the Children of Israel." That passage was clearly written after some king or kings had reigned over Israel. I could easily multiply passages like this, but one is sufficient.

The main defence offered by "Ramases" is that of traditions of the Apostolic age; but these may well have only referred to a limited traditional memory of the general Law urged by Moses, and not to the form it now exhibits. As the writers of the New Testament used words in a non-scientific sense (as when saying the Gospel had then been preached to all the world), we must not attach undue importance to words which simply chimed in with the popular theory.

We find Josephus in one part of his works giving the ordinary Biblical account of the Israelites in Egypt, and later on we find him suggesting that the Shepherd kings were the Israelites, while, if so, the Biblical narrative must be wrong. We do not find critics in that age very well versed in ancient writings, though we do know they were very credulous.

Your readers must remark that "Ramases" is a practical writer, and has access to good information; he writes with the traditions of 1,000 years or more behind him; yet they must remark what a poor show of proofs he has brought up, and must see that my contention has been well borne out.

Memnon.

ANALYSIS OF SILVER ALLOYS.

[26419.]—I AM obliged to Mr. A. Allen for his notice of my query. The circumstances which led to a desire to analyse silver-plated articles, in addition to making a fire assay of the same, are as follows. Some few years since, my employers desired me to qualify myself for taking assays of their plated articles, and sent me to London to procure the necessary apparatus. The dealer advised me to adopt a method of quantitative analysis in preference to a fire assay, on the grounds that the first method was more speedy and accurate. He kindly wrote out for me the following instructions, and supplied me with graduated instruments. I will give the exact text of his instructions in separate paragraphs, and add to each my experience.

"Weigh, say, 100 grains of the alloy, and dissolve it entirely in pure nitric acid, diluted with half its bulk of distilled water."

It was not always convenient to take 100 grains.

"This solution may next be evaporated, either to dryness, or so nearly that the free nitric acid is either expelled or so little is left that it can be neutralised by the addition of a few drops of solution of carbonate of soda."

I found that when the solution of copper and silver nitrate was evaporated to dryness, a pale blue salt was formed which was insoluble in distilled water. This same pale blue salt was thrown down from the solution when a solution of sodium carbonate was added to neutralise the acid.

"In either case the residue, when redissolved in distilled water, must be neutral to litmus paper. This neutral solution is then ready for estimation."

From the causes mentioned above, I could not redissolve the residue in distilled water, nor could I get a solution, by this means, perfectly neutral to litmus paper. An element of doubt and possible error was therefore introduced.

"A standard salt solution is then made up and used in a burette. This solution is cautiously dropped into the silver solution, and this is best used in a beaker of good size, and kept hot by occasional heating. In order to determine the precise termination of the process, it is advisable to use chromate of potash. For this purpose make a very strong solution in water, and place a few individual drops upon a white plate. When it is desired to ascertain if any silver is left in solution, it is sufficient to take up a small drop upon the end of a stirring rod, and dip into one of the drops of chromate of potash solution on the plate. If any silver is present in solution, the colour will immediately change to a blood red; if none is left, no change whatever occurs."

I procured a burette graduated in grains, and had a decinormal solution of salt made up. I also used a 4oz. beaker, and followed the instructions closely; but I could never succeed in getting all the silver down, and always noted a tinge of red in the chromate test. Even when a decided blood-red spot was shown by the indicator, I found that a considerable excess of salt solution had been added to the solution of the alloy, and in making a calculation with test samples containing a known quantity of silver, the volume of salt solution used was greatly in excess of that required to throw down all the silver as a chloride. I therefore concluded that—1, the copper nitrate in solution greatly interfered with the precipitation of silver chloride, so much, in fact, as to prevent small particles of the silver chloride from being thrown down, and thus leaving them in the supernatent solution; and, 2, that those small particles of silver chloride were dissolved by the hot nitrate of soda solution. Mr. Allen has verified my second conclusion. Will he kindly say whether or not my first was also correct? If so, will not a similar thing happen in throwing down the silver as a chloride from the stripping solution, as recommended by him.

Not only myself, but many other readers will feel deeply obliged to Mr. Allen for his *exposé* of the way in which textbooks are made up. It is a pity such books are published and sold to students. Why cannot we have textbooks written by practical analysts and assayers? A statement in Sutton's "Handbook of Volumetric Analysis," to the effect that an analysis of a silver alloy could be correctly made in a quarter of an hour, led me to suppose that it was an easy and speedy process; but I find, on the contrary, that it is more tedious, takes longer, and is more liable to error than a fire assay. Mr. Grey advises me to throw down the silver as a chloride with hydrochloric acid, fuse the precipitate, weigh the residue, and estimate the weight of silver. May I ask him how I can be sure that all the silver has been thrown down? Is it not a fact that silver chloride is soluble in a slight excess of hydrochloric acid in the presence of cupric chloride in solution? Does silver chloride absorb oxygen when dried and fused in daylight? If so, what is the combining weight of such fused horn silver? Also, how should the silver chloride be collected, in what vessel should it be fused, and how got out when fused? **G. E.**

A NEW FORM OF HEADSTOCK.

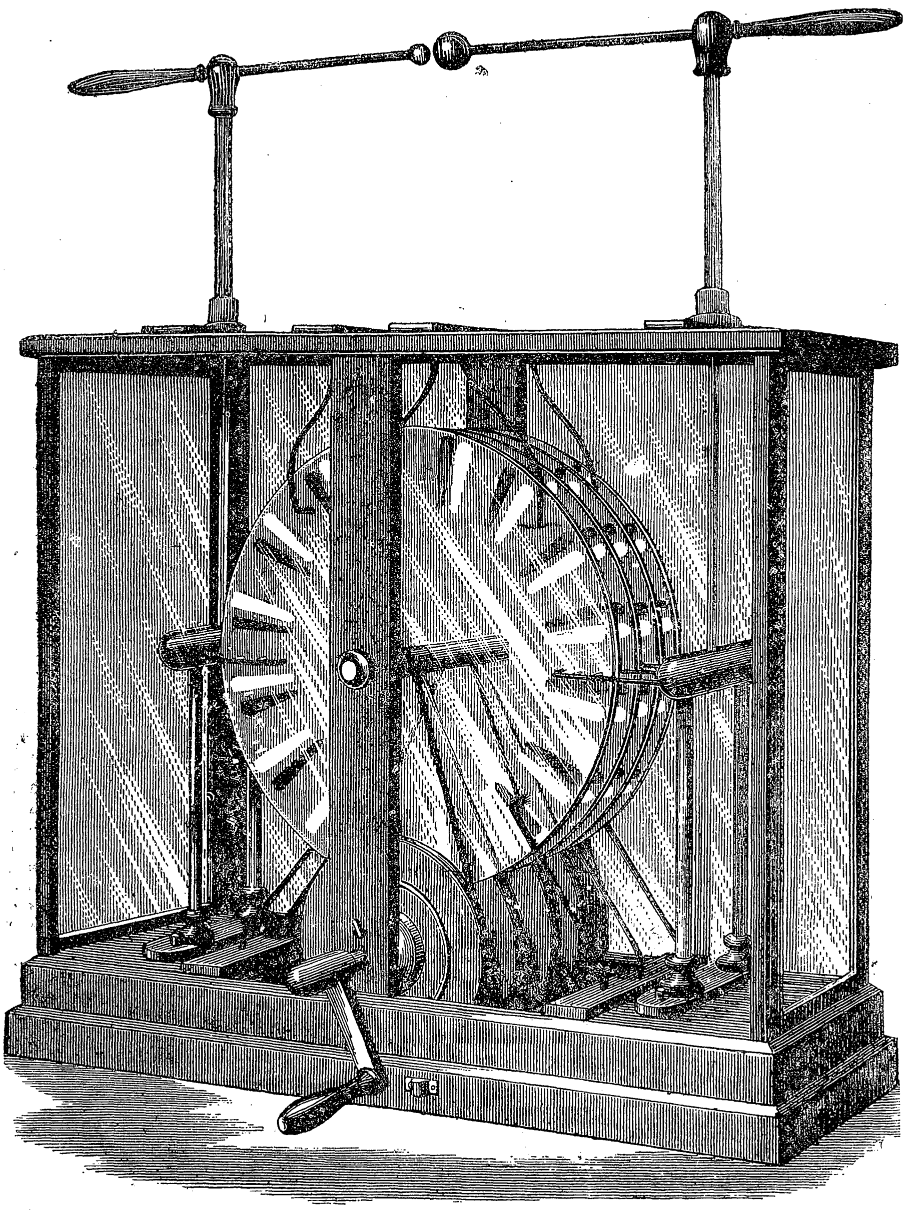
[26420.]—ON page 77 a pair of Hooke's joints are sketched at the left-hand bottom corner of the diagram.

I write to call attention to a point in connection with these.

In a single Hooke's joint, where two shafts are connected, and are not parallel, if one rotates at a uniform velocity, the other will vary in its rate of turning, so that if the complement of the angle between the shafts is a, and one makes r revolution per minute while running steadily, the other will vary its rate from ($r \times$ cosine of a) to $\left(\frac{r}{\text{cos. } a}\right)$

If the joints are placed as shown on page 77, and the shafts lie in the same plane, this variation will be doubled.

If the two jaws on the central shaft are placed parallel to one another—i.e., the right-hand coupling turned $\frac{1}{4}$ revolution before keying to the shaft, and the two outer shafts make equal angles with the central one: they will both revolve at the same rate, and the variation is got rid of. **Glatton.**



THE WIMSHURST INFLUENCE MACHINE.

By The Inventor.

[26421.]—Although in previous numbers of the English Mechanic accounts of several forms of this machine have been published, and the working details given (see 14th Nov., 1884; 16th Oct., 1885; 6th Nov., 1885) yet many of your readers will doubtless be glad to have the particulars of the working details for the more modern, or many-plated, form of the machine, similar in construction but not so large as the powerful instrument recently used by Prof. George Forbes in his lectures at the Society of Arts.

The leading characteristics of the new machines are that they have many plates, and that they are inclosed within a glass case, which to a great extent obviates the difficulties which the presence of dust offers to the student of statical electricity.

The following is a description of the working details of, perhaps, the simplest form of a machine with eight plates: a greater number of plates, or a less number of plates may, of course, be used; but then the number of parts of each kind must be proportionally increased or decreased.

The case, so far as external appearance and finish are concerned, may be left to the taste, the ability, or the pocket of the maker; but the form shown in the drawing above will probably give the greatest satisfaction. The dimensions given are measured *inside* the case—viz., $24\frac{1}{2}$in. length, $11\frac{5}{8}$in. breadth, $18\frac{1}{2}$in. height, top of base to the frame at top.

The fitting together of the various parts of the case must be left to the skill of each constructor; but care should be taken that the corners of the base, or bottom of the case, are strongly put together, so as to prevent any twisting when the machine is lifted.

The stanchions have narrow grooves cut into them, and are so arranged that each plate of the glass which forms the sides of the case is slipped into its place from the top; the grooves for the end glasses are so cut that those glasses can be lifted up at any time and taken away to enable any necessary adjustments to be made inside the case.

The driving-wheels and spindle are represented in Fig. 1. To make these procure a piece of straight bar iron, or steel, of soft quality, 15in. long by $\frac{1}{2}$in. in diameter, drill centres in its ends, then true up one end for $1\frac{1}{2}$in. in length, and on this end cut a screw-thread. On this thread screw tightly a stout washer in order to form a collar against which the driving handle can be seated. The next thing to do is to fit on to the spindle a length of wood; place the spindle with its wooden cover in the lathe, and and true up the wood, making it $11\frac{9}{16}$in. in length by $1\frac{1}{2}$in. in diameter; drill holes near each end through both the wood and the iron, and into these holes fit metal pins. This wooden portion of the spindle forms the base upon which the wheels are to be fitted and glued at the distances shown in Fig. 1. These wheels must be turned up with V grooves in their edges, and the sides slightly ornamented. After this, true up the uncovered portions of the iron spindle, so that it may run smoothly in the bearings, which are pieces of brass tube fixed into the stanchions of the case. The height for the centre of this spindle is $4\frac{1}{4}$in., measured up from the bench.

The spindle and the bosses for the glasses are represented in Fig. 2. For this spindle select a piece of bright steel wire 14in. long by $\frac{7}{16}$in. of an inch diameter, and a corresponding length of brass tube to fit the wire. Cut the tube into lengths slightly longer than those shown in the sketch, and on these lengths fit pieces of well seasoned yellow pine; turn these up to form the bosses, taking care that the projecting piece which supports the glass will just fit the holes in the centre of the glasses. Lastly, turn up the ends of the brass tube, leaving a sufficient length on each to project slightly beyond the vulcanised fibre-washer with which the glasses are held upon the bosses. The length of the projecting ends of the brass tubes regulates the distances between the plates, and care should be taken to see that no other part than the ends of the tubes touch each other when the glasses are revolving. The total lengths of the five tubes must just fill up the space between the stanchions of the case. The height for this spindle is $12\frac{3}{4}$in., measured up from the bench.

The prime conductors are represented in Fig. 3, and are made of brass tube $6\frac{1}{2}$in. long by 2in. diameter, the inside of which is filled with yellow pine; the ends are of mahogany, and are turned up to a hemispherical shape. The conductors are each supported by two glass rods, which fit into holes cut through the bottom of the brass tube and through the wood; the lower ends of the glass rods are firmly cemented into suitable stands, which can be removed from the case. The stand of each prime conductor is held in place by a steady pin at each end, and by a screw in the

FIG. 1.

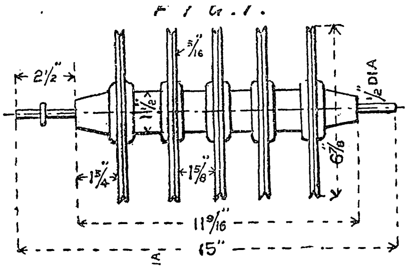


FIG. 2.

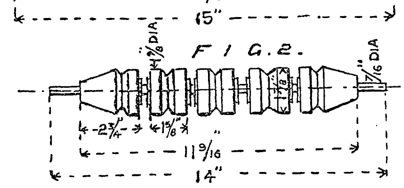

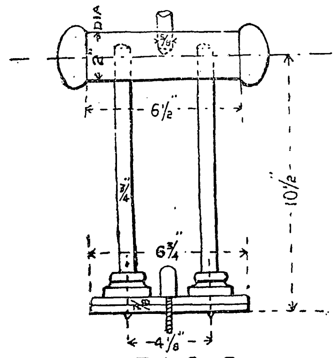

FIG. 3.

FIG. 4.

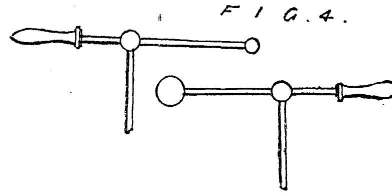

FIG. 5. FIG. 6. FIG. 7.

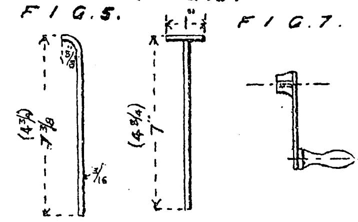


centre. It is advisable to fit a piece of vulcanite or wood over the head of these screws, as it will prevent its being a source of leakage for the electricity, and it will also make it easy to release and take away the prime conductor whenever it is required.

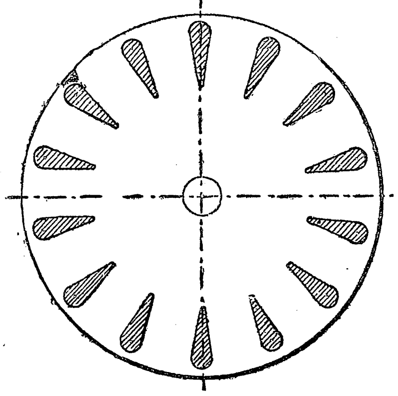
The carriers for the brushes are made of brass wire $\frac{3}{16}$in. in diam., and of a form shown in Figs. 5 and 6. Four of them simply have the ends bent to a right angle, and at the extremities small holes are drilled, into which the brushes are fixed; the remaining brush carriers are T-shaped, made up of pieces of straight wire, one end of each being filed hollow, and into this hollow a short length of small tube is soldered at a right angle to the wire: these tubes take a brush at each end. The new machine having eight plates, and, therefore, requiring sixteen brushes, four of these brushes will be held by the four carriers with the bent ends; they may, therefore, be called single carriers, while the remaining six carriers each hold two brushes, one brush being held by each end of the small tube; they may therefore be called

double carriers; the single carriers consequently together hold four brushes, while the double carriers together hold twelve brushes, thus making up the sixteen. To support the carriers, four pieces of wood are fitted, two being at the top, and two at the bottom of the case; these pieces should be so fitted that they can be removed at any time. Holes must be drilled in them at positions suitable for the brush carriers, and the ends of the carriers must be tightly fitted therein. The piece of wood at the bottom of the case upon the right-hand side of the driving handle, and the piece of wood at the top of the case to the left hand of the handle, will each support two single carriers, and also one double carrier; the brushes in these will neutralise the sectors upon the first, fourth, fifth, and eighth plates. The remaining two pieces of wood will each support two double carriers, the brushes of which will neutralise the second, third, sixth, and seventh plates. It must be borne in mind that all the carriers must be brought into metallic contact with one another: this is best done by cutting grooves in the woodwork of the case, &c., and placing copper wire in them, afterwards cementing up the grooves with shellac putty.

The collecting combs are made of guttapercha-covered copper wire, the only uncovered portions of which are the collecting points and the portion within the prime conductors; they are fastened by having one end tightly forced through holes drilled through the brass tube forming the conductor, the other end being bent to form a right angle to the glass. Sixteen of these wires in each conductor will be found sufficient.

The glass plates (Fig. 8) should be of thin, flat, and proper quality glass, 15in. in diameter. The hole in the centre should be $1\frac{1}{4}$in. in diameter. The glasses must be well coated on each side with pale shellac varnish. The sectors should be of

FIG. 8.



tinfoil, $2\frac{1}{2}$in. in length by nearly 1in. broad a the outer end, and 1·5in. broad at the inner end; they should be situated not more than $\frac{1}{4}$in. from the circumference of the plate; fourteen sectors on each plate will give about the best results.

To attach the glasses to the bosses, the best plan is to first test that the glass runs true when only lying upon the boss, then cement the vulcanised fibre washer to the free surface of the glass, then firmly screw the washer to the wood boss; but when using this arrangement, always be careful to see if one side of the glass is a little more concave or hollow than the other, and to see that the hollow side of the glass makes the surface upon which the washer is to be cemented: otherwise the plates will gape at the edges. Practice shows that the closer the glasses can be brought together the better is the result.

The handle drawn in Fig. 7 may be of any form, but the one shown answers very well, screwing it on to the spindle; the thread being cut in its boss is, perhaps, the best method of attachment. This plan, moreover, insures the machine being always driven in the proper direction, as the handle will unscrew if turned the wrong way.

The driving belts are best made of the round leather used for sewing-machines. The joint is made by scarphing the ends and stitching them together. The first, the third, and the fifth bands run straight, while the second and the fourth bands run crossed.

The terminals or discharging rods (Fig. 4) are simply straight wires $\frac{1}{4}$in. in diameter. On one end of each is a vulcanite handle, and on the other end a brass ball. The balls should differ in size, and be highly polished, the ball on the right-hand terminal should be nearly 2in. in diameter, and the ball on the left hand rather less than $\frac{1}{2}$in. in diameter. The electricity is brought from the prime conductor to the terminal by a stout wire encased all its length in a thick glass tube which extends from the conductor to the terminal. Care must be paid to see that there is metallic contact between the wire and the conductor, and between the wire and the horizontal terminal. The joint between the vertical glass tube and the terminal may be made by a wooden ball thickly polished, or by any more tasteful device.

Always remember that all glass used must be tested for insulation before labour is added to it: frequently glass is of such a character as to be useless. Avoid all sharp edges and all points: one point wrongly exposed, or even a rough surface, will be fatal to good results.

Mr. Thomas Gray, C.B., lately edited a pamphlet, which contains a reprint from the ENGLISH MECHANIC, giving particulars of the construction of all the simple forms of these machines, and how to make them. He has given a great deal of time to the subject, and was, I believe, the first to construct a machine with many plates. The pamphlet will be useful to those about to construct either of the simple forms of the machine: it may be obtained from Messrs. Pewtress and Co., Little Queen-street, Holborn, the publishers.

CHAMBER ORGANS.

[26422.]—IN common with many others, I have perused Mr. Audsley's remarks on chamber organ building with the greatest interest, and trust that it will be long before the subject is allowed to drop. It seems to me that most of our organ-building firms are utterly at sea in the matter of organs suited to small buildings, the general idea being that the *number* of stops must be in proportion to the size of the building, instead of reduced power and greater delicacy in voicing. A short time ago, wanting a three-manual organ with about 20 stops for a very small church, I found my ideas received with scorn by two of our largest firms. I was fortunate enough, however, at that time to become acquainted with the builder referred to by "Organist," who has erected for me, in a small building utterly destitute of any good acoustic properties, one of the most charming organs I know, with endless variety, and capable of effectively interpreting every style of music. I think before Mr. Landel decides on a builder, he would do well to try some of Mr. Gern's instruments, and give his work a thorough inspection, both as regards quality of tone and workmanship.

I am sure Mr. Audsley will pardon my combating his condemnation of voix céleste stops. The objection that anything systematically out of tune is inadmissible applies equally to mixture stops, the fifths in which are never in tune with the corresponding sounds on other stops. The beauty of the voix céleste does not consist in the fact of its being out of tune nor in its wavy character, but in the peculiar liquid fulness which the sharpening of one rank imparts—an effect unobtainable by any other means. I think myself that a perfect organ should have two voix célestes, one of the Gamba type, as usually inserted by Mr. Gern, and one of the extremely soft type, such as Messrs. Forster and Andrews frequently insert.

I wish some of our acoustic friends would give us their opinion in the matter of swell boxes. I fancy the grand effect of some swells is due to the acoustic properties of the box as much as to the pipes contained in it.

Another Amateur Organist.

[26423.]—I HAVE seen Mr. "G. S.'s" scales of pipes for the chamber organ Mr. G. Landel intends to build. It seems to me that Mr. "G. S." made a mistake, for I do not believe Mr. G. Landel will get a good "Gamba" out of a 4in. pipe (diameter at C C). If the Open Diapason has $5\frac{1}{2}$in., the Gamba should never have more than 3in.; and if Mr. G. Landel is able to voice narrow-scaled pipes, I should advise him to make it only $2\frac{3}{4}$in.

The Voix Celeste should not be more than $2\frac{1}{2}$in. (diameter at C C), or, referring to the Gamba, $2\frac{5}{8}$in. **W. Drechsler.**

[26424.]—I HASTEN to thank Mr. Audsley for his kind answers to my queries, but am a little disconcerted at his remark, "If Mr. Landel *seriously* intends to have all his manual stops of metal, &c." I am quite aware that most organ builders put in about one-third wood pipes; but I fail to see why this should be, except to save expense. True, some of the wood stops are extremely beautiful, but I have yet to learn they cannot be imitated, or even surpassed, by those of metal. I believe there are several French builders who now only use metal stops. In designing a chamber organ, the space it is to occupy is a most important item, and by adopting all metal stops the space is reduced fully one-third in an organ of, say, 15 stops, although the cost is thereby increased in proportion.

I shall be very much obliged if Mr. Audsley will kindly give me his opinion on this subject at an early date, as I now feel reluctant to go on with my organ until I hear from him.

I am exceedingly sorry to learn that his organ is not so perfect that he would care to publish the specification; but perhaps he will have the kindness to give us what he would consider a perfect specification for an organ of, say, 10 stops, and another of, say, 15 stops, both with two manuals. By so doing he would confer a great boon on your readers and myself, and add greatly to the value of his admirable and thoroughly practical papers upon this interesting and important subject.

I find I omitted to mention that my pedals would have an 8ft. "stopped flute" in addition to the 16ft. Bourdon, the 8ft. tone being obtained by carrying the Bourdon twelve notes higher (42 pipes in all), and fitting the pedals with octave coupler, so arranged that the 16 or 8ft. tone can be produced separately, or both together.

George Landel.

RAILWAY SIGNALS.

[26425.]—MY views on signalling have been clearly set forth in previous letters, and I have no reason to add to, nor detract from, the opinions already expressed, and I would not again occupy your space on this subject if it were not that G. L. Watkinson, page 172, has made statements, relating to myself, which are directly untrue, and therefore, require a reply.

This correspondent says that I "avoid giving a reply, direct, to 'Libra.'" This is not the fact. I have always, during the past seventeen years, given, and been pleased to give, a "direct reply" to any mechanical question that has been addressed to me in your columns.

Your correspondent publishes a letter from an engine-driver with reference to a very slight accident near Leicester, and he says that the letter is a reply to "a report by Mr. Stretton." Now, the fact is, *I made no report whatever upon the subject.* I was engaged at the Society's London Office at the time, and did not know of the account until I saw it mentioned in the newspapers. So much for the statements contained in the first part of the letter. Now to refer to the second portion. G. L. Watkinson says that I was "fully aware of his address" before I asked for it in your columns. *An* address was certainly forwarded to my solicitors, and to the editor of the *Railway Review*; but as I mentioned in my letter, page 134, it was proved to be not the *true address*, and it was further proved that the name of the writer was not "G. L. Watkinson."

The following Editorial note appears in the *Railway Review*:—

To G. L. Watkinson.—"We addressed a very important communication to you, which has been returned to us. Since then we have endeavoured to find you at the address you gave, but found you were not known there. We are therefore driven to the conclusion that you have been hoaxing us.—Ed. *R. R.*"

I do not object in the least to writers upon scientific matters adopting assumed names; but there is a limit to everything, and when *one* person under, at least, five names and false addresses, continues to write with apparently no other object than to damage the reputation of another correspondent; the limit has, I think, been reached, if not actually passed.

Clement E. Stretton.

BELLADONNA AND SCARLET FEVER

[26426.]—"XAVIER" writes no doubt with good intention, but I trust no one will be induced to rely upon the drug named if placed in similar circumstances. Is it quite certain that the child has had scarlet fever, or even that the others have not got it also? Some children have the disease so mildly that it is not recognised.

Kensingtonian.

[26427.]—"XAVIER" makes an assertion about scarlet fever and its prevention by belladonna which practice does not confirm. If he will consult any book on medicine or therapeutics, he will there find evidence that it has been tried and found not to prevent it. "Xavier" makes the same mistake as many persons do, that because they did not take scarlet fever, therefore it was in consequence of the belladonna. He no doubt forgets the fact that all children are not bound to take scarlet fever because one in the house has it. Belladonna no more prevents scarlet fever than vaccination prevents smallpox. Vaccination does not prevent smallpox, as anyone may see who will go statistically into the subject.

If parents of families want to prevent scarlet fever or other fevers, they must allow as much pure air as possible in their rooms and keep their children apart from those who have it.

The cure of measles and scarlet fever is very simple. These are the rules I treat all my cases on, and my death-rate is almost *nil*, and no ill results afterwards. I first insist on pure air; the bedroom window must be open an inch or two. In autumn or winter a fire should be kept alight. The window must be kept open night and day.

Next allow your little patients as much cold water as they like, and do not force them to drink milk or other fluids if they do not ask for them. For food they may have thin soup, gruel, milk, puddings, bread and milk, and fruit. But the most important part of the treatment is two warm baths a day—one night and one morning—at a temperature of 90° to 95° Fahr. No drugs or medicinal treatment is required. I need not remark that the use of carbolic acid, chloride of lime, &c., is injurious and useless. Condy exposed in saucers is the simplest and best. I rely on disinfection from the air that enters at the window. To destroy any germs or infection in the excreta, bed and body linen, they should be exposed to heat. Hot water is the simplest. If the linen be put in boiling water there is very little fear of infection afterwards. If parents will cut these lines out, and carry out the treatment when their children have either of these complaints, they will never rue it. I have tried drug and hygienic treatment in a great number of cases, and my experience tells me never to use drugs any more.

T. R. Allinson, L.R.C.P.,
Author of a "System of Hygienic Medicine," &c.

HORSE-POWER AND MEAN-PRESSURE DIAGRAM.

[26428.]—You are to be congratulated on the excellent way in which my diagram on p. 175 has been reproduced. There is only one error that I have detected, which was in the original drawing. Please call attention to the fact that the 200lb. line is very slightly too high. The sloping lines should cut the line of ·9 cut-off at equal intervals: it will be found that the interval between 190lb. and 200lb. is nearly 1lb. longer than the others. I would suggest that your readers may rule a red line for themselves just below the 200lb. one, which would put this right.

If they also rule a vertical one to the right of the diagram, and at a distance equal to one of the small divisions on the pressure scale from the ·9 cut-off line, it will give the H.P. and pressure if steam is carried throughout the stroke. It will just *touch* the 2's in the 20 and 200 respectively. Of course the sloping lines must be carried up to it, and if correctly drawn they will cut it into lengths *exactly equal* to those on the scale of pressures. The length of the H.P. scale is a little too great. The distance from 0 to 6 H.P. on this scale measures 199lb. on the pressure scale—it should measure 198lb. **C. H. Wingfield.**

[26429.]—In your issue of the 22nd inst. you illustrate a diagram with description by Mr. C. H. Wingfield, A.M.I.C.E., of which he says he reserves all rights.

What does this reserving of rights mean, as I have had a similar diagram for the same purpose in my possession since 1884, and I do not see how Mr. W. can claim the right to reserve that which is not his property?

I may say that I have many other similar diagrams for various purposes, and in the one I use for mean pressure I do not require a loose scale to read off the results; it is combined with the same.

A Twelve Years' Subscriber.

SIMPLE SCREW-CUTTING APPARATUS.

[26430.]—Amateurs generally experience great difficulty in chasing screws in wood or ivory with the ordinary tools.

The following easy plan is suggested as applicable to all lathes, and to every kind of material. The apparatus consists of two parts only:—

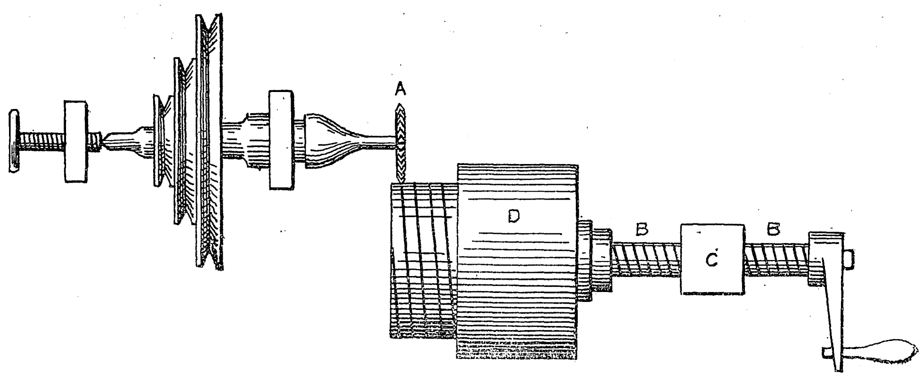
1. A circular cutter, shaped to form a V-groove, and carried on a short arm or spindle, having a socket or chuck to fit the nose of the mandrel.

2. A guide-screw, 3in. or 4in. in length, working in a nut or head held either in the tool-holder of a slide-rest, or in the socket of the hand-rest, or by an arm of its own fitted to the lathe-bed. But, in any case it must be adjustable so as to be truly level, and truly parallel to the axis of the lathe-centres.

This guide-screw has on one of its ends (to the left of the operator) a shoulder, with a screwed nose similar to that of the mandrel, so that any chuck which fits the one may fit the other. The other end is squared to carry a milled head or small winch-handle like those of the slide-rest.

The apparatus will act thus:—After turning up the object (say, a box), transfer it from the mandrel to the guide-screw. Screw the circular cutter to the mandrel. Adjust the slide-rest, or the hand-rest socket, or the arm carrying the guide-screw (as the case may be), so that the revolving cutter may make a notch on the wood or other material of the box. Then, on turning the guide-screw by its milled head or handle; this notch will be prolonged or continued as a spiral groove forming a true screw-thread around the work, of the same pitch as that of the guide-screw.

The internal screw of the lid will be similarly formed by the same cutter with equal facility.



A. The circular cutter on the lathe mandrel. B. The guide-screw, working in the nut C, carried in the slide-rest or some other tool-holder. D. The box or other work on which a screw-thread is to be cut.

The box and lid may afterwards be replaced on the mandrel, and the screws re-touched, if necessary, with the chasing tools, or otherwise finished and adapted.

There will be as many guide-screws as may be required; few amateurs will find more than three necessary. A very small cutter or two may also be requisite.

The following advantages are claimed for the above:—

1. Since the cutter may revolve with any degree of rapidity, while the motion of the work may be extremely slow, screw-threads may be wrought in materials of the most varied kind, from soft wood even to glass or porcelain.

2. By using suitable cutters, square threads, and other forms of screws, hitherto very difficult of execution in wood or soft material, may be produced.

3. As the mandrel carries the tool, while the work is independently supported, a screw may be cut upon work much larger than the lathe itself will admit.

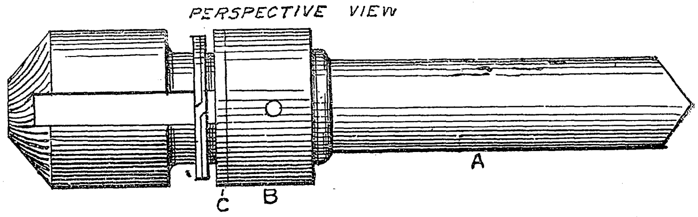
4. The whole apparatus may be constructed as a separate machine or "tool," quite independent of the lathe, with a hand-wheel to drive the cutter, and held in a bench-vice like the little lathe of the clock-maker.

5. Workmen may contrive it even for cheap wooden lathes. **W. E. D.**

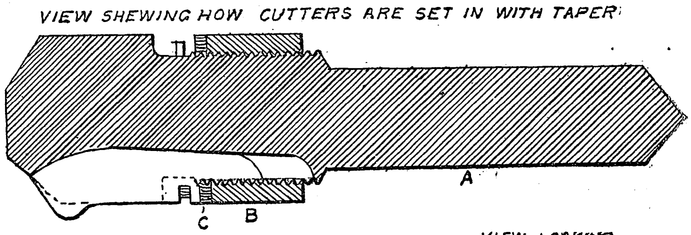
GILLIE'S EXPANDING DRILL OR WIDENER.

[26431.]—I send you drawing of my "Patent Expanding Drill," or "Rose Bit" or "Widener," which consists of a main screw spindle, A, which may be flat, round, or otherwise, with two or more wedge-shaped slots or grooves at the point, into which tools or cutters, D, may be inserted. The tools or cutters to be wedge-shaped so as to fit the

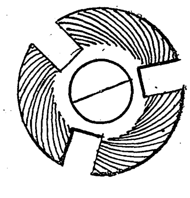
PERSPECTIVE VIEW

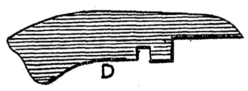


VIEW SHEWING HOW CUTTERS ARE SET IN WITH TAPER



VIEW LOOKING FROM POINT





VIEW OF CUTTER

grooves in point of main spindle A, and can be adjusted with a nut, or nut and washer, B and C, said nut, or nut and washer, to fit or come in contact with shoulders at the back of the cutting edge of tools or cutters, D, where, by screwing the nut backwards or forwards, you can adjust the cutters inserted in the grooves to make a large or small hole as may be required. E is a split spring ring so fitted into notch of cutters as to keep them from falling out of their places in main spindle.

David Gillies.

Bonnybridge, Stirlingshire.

BODIES FALLING FROM A TRAIN IN MOTION.

[26432.]—Many, treating this question, deal with it as though the body falling were of a nature to remain exactly where it fell; but an irregular-shaped object, such as a pistol, could scarcely be dropped even in a room from three or four feet high, and made to occupy the same position twice over.

I took up a key and allowed it to fall several times on the floor, but although I tried to drop it each time in a similar position, its movements were very different, sometimes remaining nearly where it fell, and again making very erratic movements, though allowed to fall each time as perpendicularly as possible, with the ring end down. When dropped at an angle the movement is different; and I advise anyone writing on this subject to try this simple experiment.

D. A.

[26433.]—A number of letters have appeared in your columns with reference to the falling of a pistol; but I fear, so far, nothing has been brought forward to clear up the railway mystery.

Your correspondents refer to "bodies let fall *in vacuo*"; but I must point out that the question before us is a pistol let fall from the window of a carriage in a train running at perhaps full speed upon a rough night.

I maintain that the moment any article is thrown from a train it ceases to be acted upon by the engine; consequently its velocity decreases, and as the train moves forward the pistol would fall on the footboard *behind* the window from which it fell. The sole question is reduced to this: When anything is thrown from a train, does it continue to travel at the same speed as the train, or does its speed decrease? Now, if its speed does not de-

crease, why does it not travel by the side of the train to its destination?

I am obliged to "Glatton" (page 173) for his reference to some "elementary book on mechanics"; but it is hardly necessary, as the subject is one upon which I passed an examination when a premium pupil to a civil engineer twenty years ago.

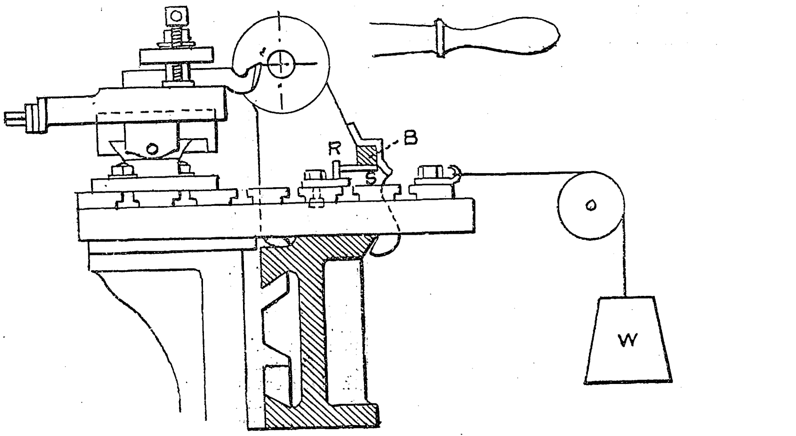
Clement E. Stretton,
Consulting Engineer Amalgamated Society of Railway Servants.

Leicester, Oct. 23.

TURNING WITH SHAPER-PLATES.

[26434.]—THE inclosed tracing of the end view of the vertical slide on page 121 shows another important advantage of the arrangement—namely, the ease with which shaper-plates can be used for turning irregular shapes, such as handles of levers (Fig. 2), and such like forms, which are required in duplicate. In Fig. 1 the long traverse screw is supposed to be removed; it is arranged so as to take out easily: a bar B is slipped into position, and firmly fixed to the headstocks, as shown: under this bar may be fixed shaper-plates, of which one

FIG. 1. FIG. 2.



is seen at S, and a small hard steel rubber R is screwed to the long slide and drawn up by the weight W. Now, as the lead-screw in the bed draws the saddle along, the rubber R, and therefore the rest and tool, will follow the curve of the shaper-plate. The two slides of the upper rest now become necessary, and the top slide is just the thing to give the feed. **F. A. M.**

HOW A BOY MAY RAISE A SOLID TON WEIGHT WITHOUT MACHINERY.

[26435.]—LET a cast-iron sinker, with a ring attached, altogether weighing a ton, be lying at the bottom of the hold of a large ship, say 20ft. deep.

Let a boy be provided with ropes 25ft. long, having an aggregate of 400 or 500 yarns. One end of the ropes to be made fast to the ring of the sinker, the other ends to be kept on deck. The ropes above the ring must be unlaid into yarns; a nail must be driven into the combings of the hold of the ship, or into the deck very near them.

One of the yarns to be pulled upwards with a strain say of 10lb., and made fast to the nail; another and another yarn to be treated in like manner, and made fast to other nails, then it will be found when 224 yarns have been so stretched, each taking a strain of 10lb., the weight will be suspended, so as to scarcely touch the bottom of the ship's hold. By continuing the process of pulling up a further number, say 224 yarns, the weight will be lifted probably an inch. The first and all other yarns in rotation, will now be partially released from their strain, and may therefore be shortened, by using the same force of 10lb., until the weight rises to the height desired.

The writer has demonstrated the above process upon a small scale. **B. R.**

THEORY OF SAILS.

[26436.]—I SHOULD like to draw the attention of those interested in the above subject to one or two points connected therewith, and that seem to have escaped Dixon Kemp and other writers.

The cause usually assigned for the increased weatherliness of a boat when heeled, and for its tendency to luff up when the heel is suddenly increased, is the superior ardency of the pressure on the lee bow. This is no doubt one factor, and in bluff-bowed or beamy boats a large one; but there are others equally, if not more, important.

The position of the centre of effort of sails appears to be uniformly found on the plan, and to be shown only in that view; no allowance is made by calculation—though actually made, as a rule, from the results of experience—for the couple, or lever, tending to turn the boat's head into the wind that is formed when the sheets are slacked, or the sails pressed over to the lee side. The horizontal plan should be taken into account, as well as the vertical one, in calculating the place for centre of lateral resistance, or of mast, &c. Also, some allowance should be made for, or an average should be taken of, the leewardness due to heeling. A vertical plan athwartships shows that at large angles of heel the centre of effort is away over the lee side, while the centre of forward resistance is very little to the lee of centre of boat.

Vulcan.

A NEW (?) METHOD OF DESCRIBING AN ELLIPSE.

[26437.]—THE day before reading your correspondent's letter in your last issue I chanced to turn over some old mathematical works of my father's, and in an Appendix to Mensuration published as a separate volume by the Commissioners of National Education in Ireland in 1857 I found the same method illustrated by a diagram essentially identical with that of your correspondent. We should be careful in receiving anything as new pertaining to mathematics of such an elementary character. **J. F. Wilkinson, B.A.**

SAFETY-LAMPS.

[26438.]—AT a meeting of the Chesterfield and Midland Counties Institution of Engineers, held at the University College, Nottingham, on Oct. 9, Mr. Clifford stated that he had seen the "Morgan" lamp exploded; it has no "shut off," which, in the opinion of many present, was a drawback to the "Morgan." Mr. Schanschieff has invented a miner's electric safety-lamp, to give 1½ candle-power for 14 hours; but it is heavier than the ordinary safety-lamp. He is working to reduce the weight. **G. E. Smith.**

PLATELAYERS.

[26439.]—AS your correspondent remarks—sufficient thought is not given by those who ride comfortably and smoothly over a mile of road in less than a minute, of the constant attention required to preserve the number of bolts, spikes, keys, trenails, &c., passed over in that short period of time in a condition to withstand the strains imposed upon them, to say nothing of the necessity of preserving the alignment, level, super-elevation of outer rails in curves, &c.

For the information of "E. M." and others, you will perhaps allow me to explain that no portion of the platelayer's work is done in the night except on some portions of the metropolitan lines, and if anyone looks at the beautiful line and level of a well-kept road, it will be apparent to them that daylight is required for this work.

The responsibility of supervising the repairs and renewals of permanent-way rest chiefly on an official who is termed the Permanent-way Inspector, and who requires years of special training to thoroughly fit him for that important position. The district for which he is held responsible will vary according to the opinions of the Engineer, the traffic, and assistance allowed him in the way of clerks, sub-inspectors, &c., and also as to how far his duties extend. On some lines he will have to take charge of not only the permanent way, which usually includes bridges, tunnels, platforms, &c., but also signals, station building, cranes, rental property, &c., while on other lines these matters are attended to by special inspectors. The districts, therefore, vary from 6 to 60 miles, but an average district will be about 25 miles, unless there are sub-inspectors, when it will generally be longer. Each inspector's district is divided into lengths, which vary according to circumstances, and on each of these lengths a foreman or ganger and a certain number of men are employed to keep the line in repair. The foreman or ganger is required by his rules to walk over his length twice each day and examine the fastenings, &c., marking and repairing as may be required.

The inspector or sub-inspector is also required to walk over every portion of his district at least once a week, and direct the ganger's operations, and also make a report to his engineer of the state of the line. Changing rails, as mentioned by your correspondent, is not a difficult or unusual operation, and in the days of iron rails on busy lines used to take up a deal of the repairer's time; but steel rails have done away with a deal of this kind of work.

Not only can rails be changed between the running of the trains, but the road is entirely relaid without working nights, as suggested, when there are as many as 80 or 100 trains passing over it during the twelve working hours.

Platelayer.

REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[59840.]—**Painting on Silk.**—I am sorry I did not notice this query until the other day. Dissolve white gum-arabic in water, about the thickness of the gum-water sold in shops; add an equal bulk of honey; mix well together, and paint over your subject with this; when dry, colour. Should the preparation crack off when dry, it requires more honey; should it be very long in drying, more gum water. It is easy to try if right on a bit of spare silk.—AN ARTIST.

[60255.]—**Hydrostatic Pressure.**—In reply to 'J. S. C.' I send a sketch of the working of this problem. It is an interesting application of the Integral Calculus. Retaining the same notation as at page 91 (Sept. 24th), the cylinder of known

FIG. 1.

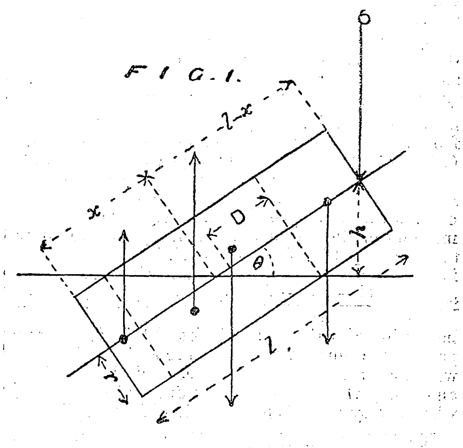


FIG. 2

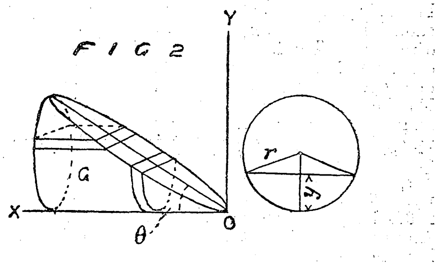

length and radius, and of given specific gravity s is suspended by a string attached to the middle of its upper end, the lower end being submerged in water: required to find the length (measuring along axis) of submerged portion with given height h of upper end above the surface of the water. The result is more simply expressed by finding the length of the portion of axis above water, or $l - x$, it is $(l-x)^2 = \frac{4h^2 l^2 (1-s) - r^2 h^2}{4h^2 + r^2}$. If we require the length of $l - x$ when the cylinder begins to take a sloping position, $l - x$ will then be equal to h; hence, substituting in above expression, we get $h^2 = l^2 (1-s) - \frac{r^2}{2}$. If r be small compared to l, the last term may be omitted, and the result will agree with that on page 91. The working is as follows:—Divide the cylinder as shown by dotted lines at right angles to its axis; this gives two small cylinders, one at each end (the centres of

gravity of which will, of course, be in the middle points of their axes), and also two equal half cylinders of shape shown in perspective in Fig. 2, the water surface forming the dividing plane; we have therefore to find the position of the centre of gravity of a body of this shape. Referring to Fig. 2, let O be origin of co-ordinates, axes of x and y as shown (this x has nothing to do with the x in the main problem). Now suppose a thin vertical slice of thickness dx to be taken at any distance x along the axis. The shape of this will be a segment of the circle of radius r, and height of segment y, the area of which is—

$$r^2 \cos.^{-1} \frac{r-y}{r} - (r-y)\sqrt{2ry - y^2}.$$

If this is multiplied by its thickness dx, we get the solid contents of the segment, and in order to gets its moment round O, we must multiply by the arm x, now $x = y\ .\cot.\theta$, and $\frac{dx}{dy} = \cot.\theta$; therefore, $x\ .\ dx = y\cot.^2\theta\, dy$, which is to be multiplied by the expression for the area. Now, suppose y to vary from O to $2r$ (the full height), we get a succession of moments of all the vertical sections, and the sum of them all will be represented by

$$\cot.^2\theta \int_0^{2r} \left\{ r^2 y \cos.^{-1}\frac{r-y}{r} - y\,(r-y)\sqrt{2ry - y^2} \right\} dy$$

Now, suppose z to be the horizontal distance of centre of gravity from O, this multiplied by the contents of the whole figure must be equal to the above expression as the moment of the whole at the distance of the c.g. from O must be the same as the sum of the moments of its parts round the same point; therefore the above expression is to be equated to $\pi r^3 \theta z$, from which we have to find z. This looks very formidable, but these definite integrals generally come out very neat expressions. The expression can be divided into three terms, each of which is to be integrated separately. The first term, when integrated between the limits O and $2r$, is $\frac{5}{4}\pi r^4$; the second term is $\frac{1}{2}\pi r^4$; the third $\frac{5}{8}\pi r^4$. The integral, therefore, reduces to $\cot.^2\theta[\frac{5}{4} - (\frac{1}{2} - \frac{5}{8})]\ \pi r^4 = \frac{11}{8}\ \pi r^4 \cot.^2\theta$, which, equated to $\pi r^3 \cot.\theta\ .\ z$, gives

$$z = \tfrac{11}{8} r \cot.\theta.$$

Some help in integrating will be found in Todhunter's "Int. Cal." pp. 20 and 50. In the same way, by taking a horizontal slice of the same body, the vertical ordinate of the $c\ g$ will be found to be $\frac{3r}{4}$, showing that it is independent of θ. It will be more convenient to give the length of ordinate from the large end so as to get the length of D (Fig. 1). This will give $D = \frac{5}{8}r\cot.\theta + \frac{1}{4}r\tan.\theta$, the last term being the distance of c.g. from axis multiplied by the tangent of θ, which gives position on axis where the vertical from c.g. acts. The remainder of the problem is ordinary algebra, as in the case at p. 91. When the work is well advanced, it will be found necessary to substitute for $\cos.^2\theta$, its value $\frac{(l-x)^2 - h^2}{h^2}$, when the result near the beginning of this reply will be obtained. If any part of the lower flat end of the cylinder is above water, a more complicated process will be required, and hence the result now obtained will not apply when the cylinder is horizontal.—M.I.C.E., Bath.

[60275.]—**New Banjo.**—Many thanks to "Sam Koe" for taking up my query; but I had the two brass rings made before your answer came, or I should have been very proud to have gone by your directions. The inside ring is thick brass 11in. in diameter, 2in. deep, with a quarter of an inch of one edge turned up, with bits cut out for the bolts. The bolts and nuts will be inside of the outside ring. There are no brackets; the nuts will work up against the ½in. edge that is turned up on the outside ring. The outside ring is thin brass 3½in. deep, made to fit around the edge—that is, turned up. The staff goes through the outside ring and is 3ft. long. I hope these few lines will explain. Any further information will greatly oblige, as I have not got it made as yet.—J. S. S.

[60306.]—**Photographic Engraving.**—Am much obliged to Mr. Saml. Ray for his notice of my query. I here give full details of the above process:—To the copper plate is applied a coating (very thin) of the following preparation: Gelatine is dissolved in water, and a saturated solution of bichromate of potash in water added; when dry, the plate thus prepared is exposed in a printing frame, and beneath the transparency to be reproduced. The time of exposure is not stated; the plate is now ready for the etching bath. The etching mordant is thus prepared: Muriatic acid is saturated with peroxide of iron (dissolved by heat). This solution is strained, considerably evaporated, and finally bottled; it solidifies into a semi-crystalline mass. Its properties Mr. Talbot supposes to be the same as those of perchloride of iron. For etching, three bottles are required—1. A saturated solution in water of this supposed perchloride of iron. 2. Five or six parts of the saturated solution and one of water. 3. Equal parts both of water and solution. The greater the proportion of water, the more easily is the gelatine softened and the quicker the acid bites. The process was invented by Mr. Henry Fox Talbot, and is described at length, and two very beautiful specimen prints given in "A History and Handbook of Photography," from the French of Gaston Tissandier, edited by Mr. John Thomson, F.R.A.S., second edition, 1878 (Sampson Low and Co.). The book states further, as matter of surprise, that the process has been but little used. Can it be from any defect in the process itself? And, if so, may my failure be thus accounted for? Shall be glad to hear again from Mr. Ray.—C. B. Roper.

[60316.]—**Electric Time Ball.**—Get or make an electro-motor, e.g., the one of which I gave a diagram in "E.M.," Oct. 1st, only double all dimensions, and put two more layers of wire on the field-magnets. It will also be very much better if you get all the parts made of wrought iron. The armature must also be different, and should be a ring-armature, with, say, eight segments, or coils; but the more the better. There should be four layers of No. 16 in each coil, so you would have to get an iron ring for core of proportionate size. The four layers would be not much more than ¼in. thick. The battery-circuit must pass up the post of the time ball and be connected at top by a mercury-contact catch (See drawings) lifting freely on

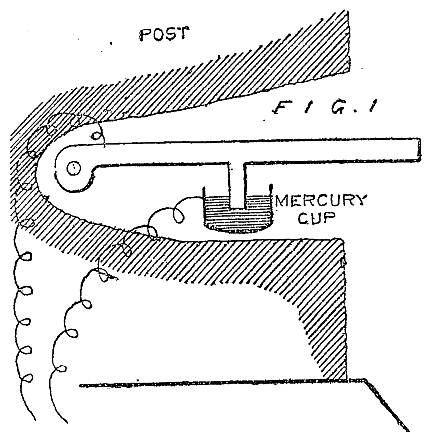

FIG. 1

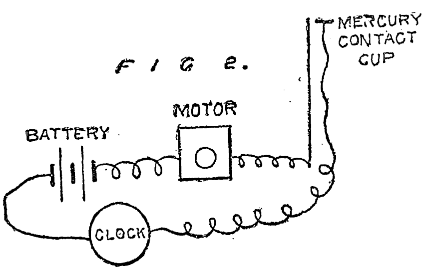

FIG. 2.

a pin, and at such a height that when the ball is at top of pole, and is caught by the brass catch I mentioned before, the top of the ball will just lift the mercury-contact out of the mercury, and so break the circuit. You must also have in the circuit a clock with a pin arranged so as to make contact with hour hand for an instant just before each hour, so that by this contact you can work a "relay" in the motor-circuit; that is a sort of electric-bell arrangement that will keep the motor-circuit open or broken, but will close it by the action of an electro-magnet worked by the clock contact. I will send you a more detailed drawing next week. Am sorry I could not write with what you wanted before; but have been very busy.—E. Conry.

[60334.]—**Falling Bodies.**—All that "E. L. G." says in current English Mechanic, p. 176, is quite right, except that he thinks that his last statement is inconsistent with something that I have said; which is not the case. Every ellipse, no matter what its ellipticity, from zero to infinity, and no matter what its magnitude, described by a body round a centre of force, the force varying directly as the distance, will be described in the same time. By the way, this is a very fortunate circumstance for the violinists. The middle point of a violin string is subject to a force having the above law; if it were not for this, Paganini himself would not have been able to play in tune.—Dubliniensis.

[60334.]—**Falling Bodies.**—The debaters of this problem have got considerably astray, I fear. I have been looking at Tait and Steele's "Dynamics"; but did not find the problem solved, as I hoped, and have not any work containing it by me. The path of a body through a non-resisting earth may approximate to an ellipse—a paraboloid is more probable, I think—but its orbit would certainly have no such minor axis as "Dubliniensis" and "E. L. G." suppose. The attracting force is directed to a centre and not to a plane, and in the latter case alone would the minor axis measure the same distance as the body would have gone if unattracted. Though the centripetal force at c.g. of earth would be 0, it would be 1 at initial end of orbit, and would never cease to pull centrewards and reduce length of axes. To calculate the orbit requires a knowledge of the calculi I do not possess; but I believe that, according to mathematics, the body would not reappear at opposite side of earth, nor would the minor axis pass through such centre. Will some one more advanced solve the problem mathematically, say "F.R.A.S."?—Vulcan.

[60334.]—**Falling Bodies.**—I did not say that it was of no use prolonging this discussion on account of the great discrepancies of the results, but that some of the assumptions made were not true. At the same time, I feel quite justified in expressing a perfectly natural surprise that one quantity (the length of the axis minor) should be variously estimated at 95ft. and 520 miles. It was assumed, I think, that the earth is of uniform density; but if this were the case, the force of gravity should decrease gradually towards the centre of the earth. As a matter of fact, however, the force of gravity at a depth of a mile is, far from being diminished, actually increased, so that a seconds pendulum at the mouth of a deep mine may gain several seconds a day on a similar pendulum at the bottom of the shaft. I may inform M. York that a body is certainly *not* retarded by that portion of the earth's crust behind it, for Newton has shown that the body is attracted equally in all directions by the spherical shell external to it, the influence of which may be, therefore, neglected. The body is then subject only to the pull of the internal sphere, exactly as though the extetnal shell did not exist. Now, as a pendulum at the bottom of a deep mine is acted on more forcibly than one at the surface, it follows that the earth is not homogeneous, and the motion of a body falling through the earth will be alternately accelerated and retarded as it passes through strata of greater and less densities respectively. In short, we know next to nothing about the interior of the earth, and that being the case, how can we presume to calculate the motion of a body, when we are absolutely ignorant as to the nature and magnitude of the forces acting upon it? Might I also suggest in a friendly spirit that some correspondents should make sure that their "corrections" are well founded before they venture to correct others?—R. E. F.

[60352.]—**Fire Engine.**—To Sam Koe.—The pattern I want is single vertical piston; two rods with cross-head, connecting rod and crank, working between flywheel close up to boiler pump down, by engineer's foot-plate. They all appear about the same size. I think the Holborn station had one of this description. I forgot in query to add diameter of hose unions. If you can oblige me I should be very thankful.—J. W.

[60369.]—**δ Cygni, &c.**—As Mr. Atkinson seems to query the accuracy of the data for this star given in the "Star Guide," perhaps I may be permitted to supplement the very full reply of "F.R.A.S.," on page 171, by stating that the position angle and distance of this star *were* roughly computed for 1886·5, as Mr. Atkinson supposes. He will have doubtless seen that there was a "screw loose" in the observation of the "practised double-star observer," whose results, by the way, as published in the *Observatory*, differ in the most remarkable manner from those communicated to the English Mechanic. I have not seen many of Dr. Copeland's measures; those few of Mr. Tarrant's which I have seen are very good indeed. I have a note on the orbit of 70 Ophiuchi in the English Mechanic for July 10th, 1885 (letter 24441, page 410). Perrotin's measures of this star last year were 26·02° : 2·077″ (4^n), 1885·502. Prof. Pritchard's (Mr. Plummer's?) elements give, for the same epoch, 44·6° : 2·64″; Herr Schur's gives 53·3° : 2·69″; M. Tisserand's, 49·0° : 2·50″. The data in the "Star Guide" (20·5° : 2·05″) were computed for 1886·5 by applying certain corrections to Schur's elements. It would seem that 17° and 2·00″ would have been more accurate; but none of the positions calculated from the above orbits for 1886·5 would have been less than 18° and 0·5″ in error. It may be as well to remark here that the large proper motions assigned by myself to a star near 70 Ophiuchi are erroneous. Prof. Asaph Hall has very kindly measured this star for me with the 26in. at Washington, and from three evenings' observations in last July he finds, for the star in question, 200·41° : 62·507″, measured from A of 70, so that there must be some very curious error in Secchi's result. For δ Herculis Engelmann gives 185·0° : 16·94″ ($6\text{-}5^n$) : 1883·29, and, therefore, the values on p. 15 of the little

FIG. 1.

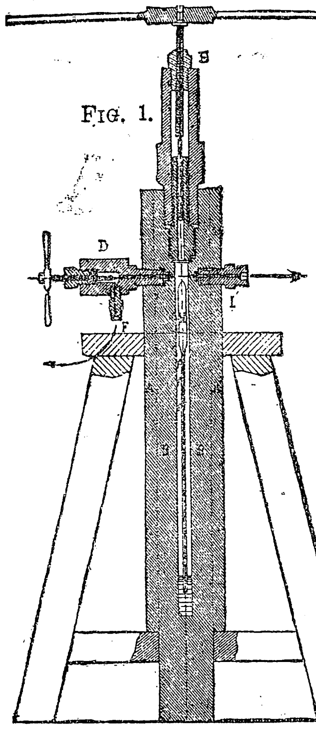

FIG. 2.

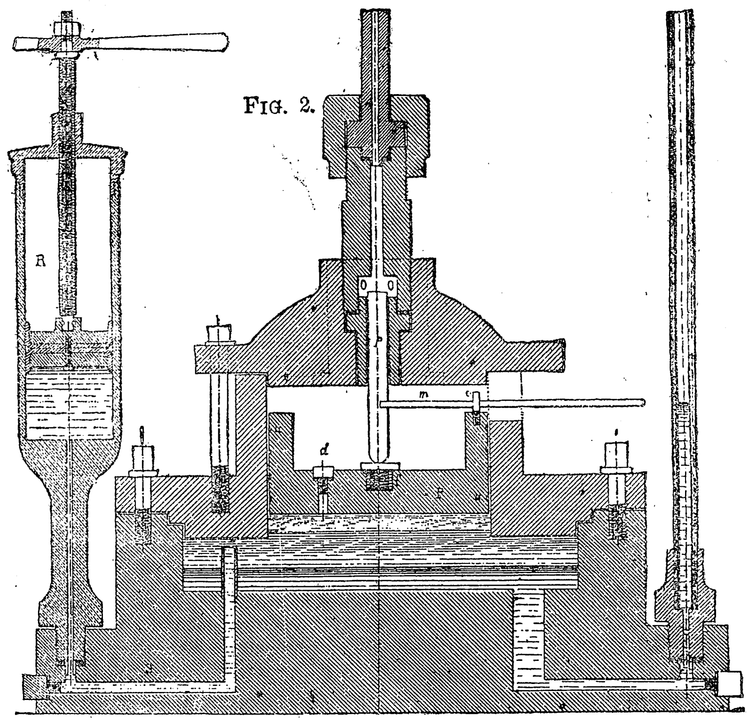


work published by Mr. Clark and myself would seem in this case to be correct enough, as also in that of ξ Scorpionis, for the close pair of which Perrotin found in 1884·53, 195·1° : 1·273″, C being at 66·8° : 7·35″ in 1883·52. The same observer could only see a very slight elongation in Σ 2525 (Cygni 22) in 1883, with a power of 1,000 on the 15in. refractor at Nice. Sir W. Herschel estimated the distance of 46 Draconis at 3½′ in 1780. The only measures I know of are those of Sir Robert Ball. The Astronomer Royal for Ireland found 160·5° for the angle, and 146·9″ for the distance of the wide, but pretty, pair in 1880. As "F.R.A.S." remarks, Secchi does not give the positions in Cygnus of the remarkable configurations he writes about in No. 975 of the *Astronomische Nachrichten* for 1855. Some of MM. Henry's photographs of the Milky Way in Cygnus, however, exhibit the wreathing and spiral structure Secchi speaks of in a very marked manner.—H. SADLER.

[60371.]—**High-Pressure Gauges (U.Q.)**—The following description of M. Amagat's apparatus for measuring the compressibility of gases at a high pressure will probably supply the information asked for:—The compressing apparatus consists of a cast-steel cylinder, B B, surrounded by a strong jacket, A A, which extends a little below the central bar of the cylinder. This central chamber contains a piezometer or a pressure gauge, inclosing the gas or liquid to be studied. In Fig. 1, a piezometer, H H, for liquids is shown. Pressure is exerted by means of a force pump, which injects glycerine through the tube, E, of a screw plug, D. When, according to circumstances, a pressure of 200, 300, or 600 atmospheres has been reached, the orifice of the screw plug is closed, and the pressure is continued by revolving the central screw, E, by means of a long lever. It is easy to see how this screw drives before it a steel cylinder adjusted with slight friction, which in turn, but without revolving, drives before it a leather capsule. The piezometer, H, containing the liquid to be tested, dips into mercury, which rises in the tube, since the volume of the liquid diminishes through the effect of the pressure. This tube is provided with several platinum wires, which are connected with each other by an insulated conductor, that establishes a resistance of 2 ohms between each of them. On a level with the screw plug D, the cylinder is provided with an insulating ring, through which the conductor makes its exit from the cylinder, to run to a properly arranged electric apparatus (two rheostats, a differential galvanometer, or other device), and then return and come into contact with the metal of the apparatus and the mercury. Owing to this arrangement, it is possible to ascertain the exact moment that the mercury touches each of the platinum wires, and to thus obtain the measurement of the volume of the liquid or gas. The pressure gauge shown in Fig. 2 is a changed and improved Desgoffe apparatus. It communicates with the compressing apparatus through a thimble, I, and a solid steel tube 10ft. in length. This pressure-gauge is provided with differential pistons, which are entirely free, and have no leather packing, and which are adjusted so as to move with slight friction. The smaller one, *p*, which supports high pressures, is rendered tight by an ingenious artifice—that is, by carefully lubricating it and pouring in molasses at *o*. In this way the piston, while preserving its mobility, is rendered absolutely tight. As for the large piston, P, which is provided with channels to facilitate lubrication, this is rendered tight without interfering with its mobility by causing it to rest upon a stratum of castor-oil floating upon a mixture of water and glycerine resting upon mercury. It should be remarked that this piston supports pressures of but a few atmospheres only—say, the height of the column of mercury in the tube, T. The rod, *m*, introduced between two pins, *c*, serves to give the two pistons a simultaneous rotary motion. Such a manœuvre is indispensable in order to give the pressure gauge perfect sensitiveness by annulling the feeble resistance that might be produced by imperfectly destroyed minimum frictions through a tangential motion. M. Amagat has found that the indications of this instrument leave nothing to be desired. To this effect he has verified it by comparison with a free column of mercury and with pressure gauges for nitrogen gas, the law of compressibility of which he has directly determined up to 430 atmospheres. It remains to be said that the pump R (seen at the left of Fig. 2) serves to regulate the quantity of liquid necessary to keep the large piston within the desired limits of its stroke. This latter should be short enough to prevent too great a lengthening of that of the small piston which supports all the stress. At *f* is seen a steel bolt, against the head of which abuts a plunger, *p*, and at *d* an orifice which is usually closed by a screw, and which is designed to allow the air to escape while the piston is rising. It is of interest to add that the piston, *p*, can be removed at will, and be replaced by duplicate pieces of various diameters. In the apparatus shown herewith the ratio of the surfaces is such that the mercury rises 6½ft. at T at a pressure of 1,500 atmospheres. As the column of mercury in M. Amagat's laboratory is not less that 16ft. in height, it has been found possible to exceed the enormous pressure of 3,000 atmospheres there, while no inequality could be detected in the operation of the apparatus.—E. R. J.

[60385.]—**Work on Carpentry and Joinery.**—"Nemo" apparently wants a work specially written for his benefit. If Tredgold's "Carpentry," Aveling's "Carpentry and Joinery," Holly's "Carpenter and Joiner's Handbook," "Carpentry and Joinery for Amateurs," and the many excellent articles published in your columns, will not satisfy his wants, he had better take some lessons from a professional. Any bookseller will supply the works above named, or "Nemo" can write to Lockwood and Co., Trübner, and Gill, for their catalogues, or procure Mr. Calvert's list from Gt. Jackson-street, Manchester.—SAML. RAY.

[60390.]—**Carving.**—Mr. T. Wood should really say what it is he wishes to know. There have been some excellent articles on wood-carving in back volumes, and if the information is "too meagre," perhaps if Mr. Wood asked a specific question he would obtain a suitable answer. Perhaps the "Instructions in Wood-Carving," published by Crosby Lockwood and Co. at 2s. 6d. would meet his wants.—NUN. DOR.

[60399.]—**Electrical Foot-Warmer.**—If M. Rabache has an invention so useful as he describes, why does he not patent it, or give it free to one of the railway companies?—SELIM.

[60407.]—**3in. Telescope.**—This querist will find all the instructions he needs in Vol. XXXIV., pp. 535, 607, 621, or in the previous volume.—NUN. DOR.

[60408.]—**Iron Workshop.**—There is no reason why an iron workshop and showroom should not do; but it must be well ventilated and kept warm.—O. L. P.

[60416.]—**Portable Forge.**—This query reminds me of the man who had a watch that would not go. He wanted to know what was the matter with it, but would not allow any one to look at it. Possibly if "Moorgate" gave some idea of his difficulty with the portable forge, he would get the instructions he requires.—SAML. RAY.

[60425.]—**Hard-Soldering Aluminium.**—Is not "W. S. F." asking for the impossible? At any rate, can aluminium be hard-soldered? However, see p. 156, No. 1074, and p. 523, No. 1091.—NUN. DOR.

[60426.]—**Nickel Polishing.**—"Polisher" seems to have left out the one material which is used successfully for polishing nickel—viz. Sheffield lime. The bob or buff—"dolly" it is called—is made up of many layers of unbleached calico, and the lime in powder is used with a little oil. N.B.—The lime is not thrown away. Like other polishers, it acts best when charged with fine particles of the metal. The query is headed "Nickel Polishing," but it may be nickel silver.—SAML. RAY.

[60428.]—**Silvering Glass.**—To "GLATTON."—Almost every back number contains some information truly, but not complete, considering that you quote eleven volumes since, which, I daresay, hundreds of us cannot get at. I don't think it too much for you to condescend to give us a résumé with your own experience, if any. I only require for small surfaces. Please give commercial name of chemicals.—ENQUIRER NO. 2.

[60429.]—**Electric Pen.**—I presume the querist knows that the electric pen is a patent. It is simply a small electro-motor which drives a steel point through paper, as the "pen" is traced over the sheet. The paper is then used as a stencil in the ordinary manner. Electric pens which I suppose are free from patent-rights were described in Nos. 742 and 746.—NUN. DOR.

[60431.]—**Lattice Work.**—I suppose that fine steel lattice work will answer; but it is impossible to fix the letters to nothing, and if something is employed it will surely be visible.—NUN. DOR.

[60432.]—**Architecture, &c.**—It is a principle that whenever adverse criticisms are made, any explanations on the other side should be heard in reply. In regard to the adverse criticisms referred to by "Delta," it should be mentioned that the late Mr. Street published a pamphlet giving a vigorous and warm reply to his critics, and in which he cited the *Architect*, the *Building News*, and the *Athenæum* as having published favourable notices of his designs for the New Law Courts. The editorial

articles, however, in the *Architect* were decidedly hostile to Mr. Street's design, as will be seen by perusing the number of Sept. 9th, 1871. In the list of journals mentioned by "Delta," which published criticisms in "torrents of execration" against Mr. Street's designs, there are two—the *Times* and the *Illustrated London News*—of which no account would be taken by the "professional" publications, because forsooth they are only "popular journals." It is indeed a fact that the technical journals in the building trade affect a contempt for the opinions of the public, and even for the opinions of artists other than architects to a degree that is really amusing. Pity such artists as myself, who cannot boast of having soiled our hands with brick and mortar! Are we to be frightened out of utterance at the attitude of a scarecrow labelled with the word "professional"? The aforesaid criticisms of the *Times* were reproduced in full in the next-published issue of the *Building News*. On this subject there is one matter which is deserving of notice here. We have the authority of an article in the *Architect* of Sept. 30th, 1871, for believing that "it was Mr. E. W. Pugin whose influence turned the scale in favour of Mr. Street." Those influential and favourable criticisms of Mr. Pugin (since deceased) were published in the *Times* of June 23rd, 1868, and also in previous numbers, but subsequent to that he changed his opinions in an extraordinary manner, and published in the same journal on Sept. 13th, 1871, and January 22nd, 1872, criticisms the very reverse of the former, and even calls on the representatives of the country to save themselves from "an unparalleled degradation." It would seem accordingly that the selection of Mr. Street's design was based on the indications of an *ignis fatuus*, so that the whole thing is really provocative of much laughter. With regard to the "battle of the styles," I would myself be in favour of Classic rather than Gothic for secular buildings. Whatever can be said, the Gothic always has a clerical and gloomy appearance, and I am not at all fond of clerical domination except in the proper cause. Classic architecture has a proud and manly expression of appearance as opposed to Gothic. The ultra-Gothicists go in for producing extremely moderate or "subdued" effects, and proceed to eliminate all manly features of expression from their designs until the whole has entirely an old-womanish aspect—what might be called the Mrs. Harris and Mrs. Gamp style. Mediæval Gothic architecture was entirely abandoned in practice just at the time of the Reformation, and, therefore, it can have no claim to Protestant nationality. My own idea of a grand style of architecture for large public buildings is the Classic, as distinguished from Renaissance, and this idea was advocated in the *Builder*, March 20, 1869, and in the *Times*, May 30th, 1868. As to the books to be recommended to "Upsilon," I would include "Sir William Chambers on Architecture," Viollet-le-Duc's "Dictionary of Architecture," and the works of Inigo Jones, published by Lord, Burlington, and Kent.—AN ARTIST.

[60433.]—**Manure.**—There is no work which answers to the requirements of "Severan"—probably for the simple reason that the sale to be expected for such a book would not cover the expenses of printing. He will find much useful information in the cyclopædias, and in works of analytical chemistry. There are Sibson and Voelcker's "Agricultural Chemistry," and Ville's "Artificial Manures"—the latter, 30s., I think—which may help the querist.—SAML. RAY.

[60439.]—**Petroleum Engine.**—This querist should procure the specifications of the patent. Spiel's was illustrated some time ago in one of the engineering papers.—SAML. RAY.

[60441.]—**Engraving Ivory Tablets.**—This process is just the same as engraving brass, and a set of tools can be obtained at almost any tool shop. Ebonite and celluloid are probably not engraved at all; but moulded up with the letters required. Any ivory cutter would sell suitable pieces at a comparatively cheap rate.—SAML. RAY.

[60443.]—**Japanning.**—Did "Harry" ever see a baked-potato oven in the streets of London? If so, he has an idea of a "stove" that will do for japanning. All that is wanted is a chamber which can be heated to from 250° to 300° Fahr., and, of course, the "stove" may be set in brickwork to prevent radiation of the heat. Care must be taken that the door shuts close to prevent the access of dust.—NUN. DOR.

[60484.]—**Twilight.**—The faintest stars are not reckoned of the "sixth magnitude," but at least the fourteenth; and there must be some interval between the first visibility of Ptolemy's faintest (called sixth magnitude) and that of the fourteenth in any telescope, which interval is part of the twilight. It will take a first-rate astronomer to assure me that either sixth or fourteenth ones were visible on October 17th within an hour of sunset. I have read Humboldt's South American travels, but found no mention of twilight ending before the sun must have been depressed 18°; and been in the same latitudes without finding any such. The zodiacal light always drowned the fainter stars between W.S.W. and W.N.W., up to 30° or 40° of altitude, for fully three hours after sunset; but this I do not confound with twilight. Of course, in typical English weather, that rarely allows stars to be seen, nobody can say when twilight ends. We have had London fogs that made noon darker than any night, because the public street lamps were not lit as they are by night.—E. L. G.

[60537.]—**Problem.**—The angle A D B being known, draw a circle through A B D, having its centre G. Join A G, B G, D G, and C G, then A B G will be an isosceles triangle, having angle A G B = 2 A D B. Assuming a value for A B, we may find the triangles A B G, A B C, and C B G, D C G = 180 + B C E − B C G. In triangle C D G we have C G, D G, and D C G, from which we may obtain D C, and thence A D C.—H. K.

[60540.]—**Tricycling Matters.**—I am obliged to G. Townsend for noticing my query about small *v.* large wheels, and automatic steering; but I must frankly say I do not find his suggested explanation satisfactory. It does not commend itself to my mind as at all sufficient to account for the superiority of the former, assuming it to be a fact. As to the discussion of this point in the cycling press, I regard it as absolutely valueless. Only a very small number of cyclists have any knowledge of mechanics, and of these a still smaller number possess more than a mere smattering. I find cycling literature, with very few exceptions, simply beneath contempt, especially upon mechanical details. I am glad to learn that the "stuffing-box" system for the steering wheel is superseding the so-called "automatic" system, which latter would be to me very trying indeed; the more so as it seems to involve the use of a cross-handle as a necessity. As far as my experience goes, "automatic" steering appears to be an absurdity; as you can very rarely proceed far in a straight line without encountering all the irregularities of the road, which can, by skilful and rapid deviation, be avoided—making all the difference to the comfort and enjoyment of the rider. Personally, a cross-handle steering bar I regard as an abomination, though I admit that is purely a matter of opinion. I can quite believe that one who has been used to riding a bicycle may prefer it; but I regard the spade handle as infinitely preferable, provided it can be arranged so as not to be turned aside by every trifle, and that I presume the "stuffing-box" should effect. My ideal is an arrangement with spade handles, so that either hand can be employed for steering, according to circumstances, and it would be a boon also for either hand to be effective with the brake.—GAMMA SIGMA.

[60562.]—**Current Quantity.**—Thanks for the many replies to my query. I did not expect to calibrate my instrument with any great accuracy; but if I could set up a battery, either the single-fluid bichromate or chromic-acid cell, or an accumulator, I thought I might calibrate very near. I might say that the resistance of my instrument is very little, being only a strip of copper 1in. wide and $\frac{1}{16}$in. thick. Perhaps some one might tell me about the current that is given with an accumulator of so many square inches surface exposed, with distance apart, fully charged.—C. R. W.

[60574.]—**Astronomical Photographs.**—The photographs of Mr. Common and MM. Henry cannot be obtained by purchase. The reproduction of the Pleiades by heliogravure is headed "Annales de l'Observatoire de Paris, Atlas," and possibly, therefore, "S. P. C." might be able to procure this, in the same way as Chacornac's Star Charts are sold. I believe that Browning, in the Strand, sells small copies of one of the Melbourne photographs of the moon for 2s. 6d. each. These and the lunar photographs of Mr. Rutherfurd, to which Mr. Franks refers, are, so far as I am aware, the only ones which can be obtained by purchase. Some small copies of Rutherfurd's are to be found in Proctor's "Moon."—H. SADLER.

[60600.]—**Musical Intervals.**—In my reply on p. 178, delete the word "tempered."—N. E. CHILD.

[60603.]—**Magneto-Electric Machine.**—This will form the subject of my next article on "Electrical Instrument Making for Amateurs." Will you forgive me if I ask you to wait till that appears?—S. BOTTONE.

[60604.]—**Resistance Coils.**—When the bridge is fitted up with coils, all that is needed is to place the unknown resistance in one of the gaps of the bridge, and remove the plugs which throw the different coils into circuit, until the galvanometer needle shows, by remaining motionless, that a balance has been attained.—S. BOTTONE.

[60610.]—**Fluorine.**—In reply to Mr. W. J. Grey's question, the statement that fluorine had been isolated was seen in the report of Mr. Crookes' Address at the British Association meeting, given at page 30 of the ENGLISH MECHANIC of the 10th ult. Many thanks to "F. J. C." for the information kindly supplied.—L.

[60622.]—**Astronomical.**—The aperture in these toys has to be oval, because the map is on a projection that makes any circle except the equator and its parallels a distorted oval. Therefore the horizon has to be so represented, and, what is far worse, the east and west points of it cannot be opposite. Nor would they be any better placed were the horizon made circular by using the kind of map (stereographic) that makes every circle appear a circle. The southern constellations would be greatly more expanded than the northern; as, indeed, the southern points of the compass are in any case. A planisphere made for St. Petersburg would not be quite so distorted; but for London, or still more any lower latitude, the contrivance is hardly more than a toy. A set of twelve, or even only eight, stereographic projections of the visible hemisphere, each extended E. and W., to show the stars about to rise or only lately set, would be far better.—E. L. G.

[60623.]—**Dynamo.**—When a dynamo maker states that a machine gives 200 ampères and 100 volts, he means, of course, through a resistance of 0·5 ohm. The output of a shunt machine can be varied to a very great extent, but not in the manner you suggest; for instance, take a machine giving 50 ampères at 100 volts, the machine would give 50, 60, or 100 volts, and currents of 75, 50, 25 ampères, or, in fact, any combination between 75 ampères and 25 volts, or 25 ampères and 100 volts; but it certainly would not be safe to take 100 ampères and 25 volts. Taking the machines of good makers, they will give a current 50 per cent. in excess of their normal amount without injury; but it would not do to try this experiment with the cheap machines, as most of them will barely give the output they are advertised at. If a large shunt-wound dynamo were short-circuited, it would certainly pull up the engine or slip the strap off; but if the engine was powerful enough to keep it going, it would probably injure it; of course, directly it was short-circuited all current would be cut off from the F.M.'s, so that the strain on the machine would only last a few seconds. If a series machine was short-circuited while being driven by a powerful engine, it would certainly be destroyed, as would also a compound-wound dynamo; this catastrophe is avoided in practice by the employment of fusible cut-outs. The hot resistance of an incandescent lamp is found by dividing the E.M.F. in volts by the current in ampères.—S. AND E., Coventry.

[60625.]—**Astronomical.**—Oh that "Vortex Atom" had only exercised a little of that common sense which, no doubt, he is in the habit of using in sublunary matters, instead of asking such a ridiculous question in "our" pages! I fear his knowledge of the phenomena of the phases of the moon is very crude, and should recommend him to expend sixpence in the purchase of some elementary primer on astronomy. "Why is it that we are not always able to see the whole disc more or less brilliantly illuminated?" Simply because the "earth-shine," or, as the French call it, "la lumiére cendrée," is too feeble in comparison with either the splendour of the sun's rays, when the moon is near to him, or with the reflection of the same from her surface as she brings more and more of the illuminated portion of it to our view. Let "Vortex" face the sun when shining brightly, holding a roughened white ball in his hand on the same level with the sun, but about 45° to the left of him. This represents the moon's position with regard to the sun when nearly four days old, he will then see that besides the crescent of light on the right of the ball, he is able to see the whole of the disc. This is due to the reflection of the sun's light from his own shining face, which aptly takes the earth's place. As he now carries the ball more to the left, turning round with it, he will find that as the crescent increases to "full," the "earth-shine" decreases. This arises from two causes: the one is that the crescent of sunlight reflected from his own face is diminishing, regarded from the ball; the other is, her brightness is increasing. Having carried the ball round to within 45° of the sun on the right, the earth-shine is again plainly visible; but as the ball is carried past the sun, it becomes totally black on the side nearest him. Does he not know that even the electric arc appears black against the sun? The inclination of the moon's orbit to the plane of the ecliptic (the earth's path round the sun) is little more than 5°—about five times the sun's own apparent diameter—therefore she can never pass further than this from his centre when in conjunction with him. I cannot help here remarking on the gross ignorance so frequently displayed on the simplest matters connected with the science of astronomy by otherwise "well-informed" persons, and, further, on their total want of shame in manifesting the same. A man may say, "I know nothing of chemistry or mechanics," without the slightest cause for our depreciation of him personally—these studies may not have come in his way; but for a civilised man never

to take the trouble to acquaint himself with the sublime, yet free, reiterated phenomena of the system of the universe, forced as it were on his notice, seems to me to be a wicked, as well as shameful neglect. It is not long since a man I know, holding a responsible position under Government, said to me and the company in a public place—"Oh! what you call the mountains in the moon are simply the reflection of our own mountains—that's all." Nobody contradicted him; I regarded him with mingled disgust and pity. When I was a boy of eight, I knew every named star (besides many lettered ones) visible in our heavens, and was never tired of "spotting" them out, and I remember a servant girl of ours once saying, "Oh, Master George! you should not have anything to do with star-gazing—it's wicked!" This shows what injury astrology has done to the popular study of astronomy. The cause of the apparently greater size of the bright portion of the disc is the optical delusion called irradiation, which causes all brilliant objects to appear larger than they are. This has been designated as "the old man in the new moon's arms."—GEO. BELL.

[60634.]—**Miners' Safety-Lamps.**—In giving my opinion as to the superiority of the Morgan safety-lamps over all others, I did so as one of the public anxious to find out the best and safest lamp for underground work, and as engineer to the Universal Electric Light Company I made some very severe tests, as previously stated, with the sole object of finding out the best oil lamp I could procure, and recommend my Company to take up, to work in combination with a new electric system about being introduced by them for colliery electric lighting. I am a thorough believer in lighting the main ways and various other parts of the mine by electricity, generated at the pit's mouth for safety's sake. Finding there was no practical portable electric lamp, or likely to be one, that could be placed in the hands of a miner to fulfil the necessary conditions, and also objections such as weight, cost of maintaining lamps, difficulty of charging, and many other matters known only to electricians—knowing these facts, I came to the conclusion that we must still rely on the best oil lamp obtainable to fulfil the requirements of the working collier, and after hundreds of tests I am convinced that the "Morgan Patent Safety-Lamp" of the newest type is the one best suited for this purpose. It is light in weight, simple in construction, gives a good light, and burns well in any atmosphere, and, above all, the lamp is very safe, and cannot be exploded, in my opinion, under any conditions likely to occur underground, and until I can find a better lamp I shall continue to use it, and recommend its adoption whenever I can. Price should be no object for a good lamp where life and property are at stake, and I have not the least doubt that many explosions have been brought about by the use of the cheap, so-called safety-lamps now in use. Mr. Palmer objects to wire gauze. Why? He would not do this if he knew the practical value of it when worked in combination with a double shield and air-space divider as used in the Morgan lamp. Mr. Rhodes is a well-known authority upon the subject under discussion, and it would be interesting to know from him if he has succeeded in exploding the "Morgan" lamp. If so, by what apparatus, and at what velocity? Like Mr. Clifford, I am not a betting man; but nothing would give me greater pleasure than to contribute, say, £20 with 49 others, to form a fund of £1,000 to defray the expenses of a public test of all miners' lamps now in use, the competition to be open to all inventors and makers of lamps. The experiments to be carried out in the presence of scientific experts, the Press, and the competitors themselves. After all expenses are paid, the balance in the hands of the treasurer to be divided between the inventors of the three best lamps, as 1st, 2nd, and 3rd prize. The public would then know whose lamp was worthy the name of "Safety Lamp." I am sorry I cannot give a full description of the Morgan testing apparatus used by me for the present, as published information might tend to invalidate Mr. Morgan's patent, as I understand the apparatus is not yet fully protected abroad by patent, but shall be happy to do so as soon as the specification is published. I think if Mr. Palmer will read my comments on this subject, he will see that I clearly stated I had not tested the McKinless lamp, but should be happy to do so, and publish the result of my experiments in the "E. M." for the benefit of its readers, this being a subject of national importance.—ARTHUR SHIPPEY.

[60638.]—**Photo Lenses.**—I regret to say that I am so fully occupied that I cannot find time to write such an article as I should like on the gelatine process. But as soon as I have cleared off my arrears of work I will endeavour to send the information "B." requires.—S. BOTTONE.

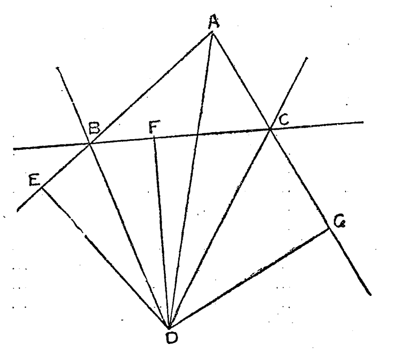
[60643.]—**Electrical.**— ERRATUM.— For relative resistance of shunt to armature in dynamos, for "$\frac{16}{20}$ to 1," read "160 to $\frac{1}{2}$."—E. CONRY.

[60645.]—**Faulty Watch.**—If the escapement is too deep, you can easily correct it. Take your screw-driver, and put point of it in space left between bottom cock and plate, and give it a slight tap with a hammer. This moves bottom cock back a little, and consequently shallows escapement. The banking pins might not act properly for another reason: The banking pin in balance might be short, or balance might be too high or low, and so miss banking pin in cock.—J. H. D.

[60646.]—**Cracked Gongs.**—The jarring noise is due to the two sides of the crack rubbing on one another; and if you separate them by running a fine saw down the crack, the tone will again become clear; but it will never be quite the same as before.—GLATTON.

[60646.]—**Cracked Gongs.**—Some years ago I had a 6in. bell-metal clock gong, which got cracked. I tried the method of cutting along the crack with a fret-saw, as I see recommended in the "E. M." this week by Mr. Ray, but found the metal so extremely hard that the saw made very little impression upon it. I then tried another plan, which succeeded very well indeed. Take the gong in a light pair of smith's tongs, and with a stick or a brush moisten the crack all along on the inside of the gong with ordinary soldering liquid (zinc dissolved in spirit of salt). Then heat the outside, but not to redness, in a powerful Bunsen flame (a clear fire would do as a substitute). Rub all along the crack with a stick of ordinary tinman's solder until it is filled in, then cool as slowly as possible; leaving in a fireside oven all night does very well. Next morning, with a fine file, remove all solder which may have run through the crack to the outside of the gong. Great care must be taken both in heating and cooling to do it as gradually as possible, to avoid unequal expansion and consequent extension of the crack.—A YOKEL.

[60650.]—**Geometry.**—Let A B C be a triangle and let the bisectors of the exterior angles at B and C meet at D. Join A D, then the angle A is bisected by the line A D. Produce the sides A B, A C, and draw from D the perpendiculars D E, D F, D G. Then in the triangles D B E, D B F, we have the angles at E and F right angles; the angle E B D = D B F (since E B F is bisected), and one side B F common; hence (Euc. I. 26) D E = E F. Similarly, it may be shown that D F = D G; hence D E = D G. Therefore, in the two triangles



E A D, G A D, we have the angles at E and G right angles, the side E D = D G, and A D common, and since $AD^2 = DE^2 + AE^2$, and also $AD^2 = DG^2 + AG^2$ (Euc. I. 47); hence $DE^2 + AE^2 = DG^2 + AG^2$, and since $DE^2 = DG^2$, therefore $AE^2 = AG^2$, and $\therefore$ AE = AG. Hence, in the two triangles E A D, G A D, we have the three sides in the one equal to the three sides in the other each to each. Hence (Euc. I. 7) the triangles are equal in every respect, and therefore the angle E A D = G A D, or the angle A is bisected by A D. (Q.E.D.)—J. E. GORE.

[60651.]—**Electric Signals in a Mine.**—Thanks to E. Conry and "C. D. R." for last week's, but would like some particulars as to battery, and I scarcely understand the former when he speaks about the different sorts of indicators, not being very conversant with electrical terms; but I can scarcely think that the gases of the mine had much effect on the wires, for it was in the shaft itself where we had the most to complain of, and being a downcast shaft there cannot be any gas more than at the surface. Our first wire was a single untinned copper, No. 15, coated with india-rubber, about $\frac{3}{16}$in. diameter, and in a short time after laying down wanted repairing every few days through "oxidation," the second was a 3-wired one stranded together, which insulated separately, each wire No. 20, untinned, covered with gutta-percha and one lay of cotton, in all about $\frac{1}{4}$in. diameter; this was much the best of the two, but in about three months after putting down failed as the one first put in. They were not cased, but sheltered under some wood pipes; it was in the driest part of the shaft where the mischief lay, as the wettest kept good.—A. O. H.

[60662.]—**Solution of High Specific Gravity.**—A solution of high specific gravity may be made by dissolving mercuric iodide in a strong solution of mercuric chloride.—A. E. F., Manchester.

[60669.]—**Gut Driving Bands.**—The gut is tapered slightly at the extreme end with a sharp knife, so that it will just enter the screw-hole in the hook; it is then screwed in until it projects from the other end into the hook or eye, as the case may be, and the projecting end is burnt with a red hot wire, which causes it to swell and prevents it from drawing out of the screw.—G. J. M.

[60673.] — **Mechanics.** — Assuming that there are 12 joists, each will sustain a load = (1cwt. × 12ft. × 12) = 1344lb., which will produce the same bending moment as a weight $= \frac{1344}{2} = 672$lb. at the centre of the joist, assuming that the ends are not fixed rigidly into the wall. The width of a beam, as compared with that of another of the same material, will vary as $\frac{w\,l}{d^2}$ where w = load at centre to break beam, l = length of beam in any units, and d = depth of beam. In your case, the breadth will have to be such as to allow the beam to break with (672 = a factor of 6) = 4032lb.; hence—

$$\text{Width} = 2\text{in.} = \frac{4032}{1000}\text{lb.} \times \frac{144}{50}\text{in.} \times \left(\frac{2}{10}\right)^2 = \cdot 927\text{in.}$$

—GLATTON.

[60674.]—**Strawberries.**—Has it never struck "Lady Gardener" that using "the contents of the slop-pail to water the plants" might be the cause of the failure pure and simple?—HENDON.

[60674.]—**Strawberries.**—There is no reason why our "Lady Gardener" should seek new ground for her strawberry plants; for, if properly top-dressed, a bed will last six or seven years, and anyhow all that is necessary is to trench the ground—that is, bring up the "spit" underneath the top to the surface, and put the surface spit in its place. This, however, is best done in the autumn, so that the winter's frost can have full effect on the soil brought to the surface, and it is well, too, to do only a portion of a large bed at a time. I do not know of a single plant which sends anything but tap roots into the subsoil; the tap roots draw water, the feeding roots are the slender fibres which are invariably near the surface—consequently, if ground is trenched, the surface is practically new ground. Our "Lady Gardener" will not want dissolved bones if she has bone dust: the former is, or should be, bones dissolved in sulphuric acid and mixed with some dry powder; it does not contain more than is in the bone dust, but is in a condition to be more readily assimilated by the plants. The bone-dust lasts longer, but is not so powerful—that is all. The sulphate of ammonia, nitrate of soda, &c., can be obtained readily enough of the dealers in artificial manures if ordered in quantities; but they are goods that require a lot of care in keeping, and I am obliged to pay 4d. and 5d. a pound for the small quantities I require, which I generally obtain of drysalters or dealers in photographic chemicals. If a "Lady Gardener" lives in the country, she might be able to get a friendly farmer to let her have half a cwt. or so at the price he pays; but if that is impossible I would advise her to look in the columns of the *Gardeners' Chronicle* or the *Journal of Horticulture* for advertisements, or send to Mr. Smyth, of Goldsmith-street, Drury-lane, London, for his list of horticultural requisites. As to the green vitriol, that is sulphate of iron, and can be bought at most oilshops. If the soil is of a clayey character and a lump of it burnt in the fire is red in colour, I should think iron is not needed; but no harm can be done by dressing the ground with an ounce to the square yard. There is no reason why guano should not be used as a manure for strawberries, but great care must be taken that it does not touch the fruit, and great care must also be taken to get your value for your money when you buy guano. A few years ago I bought some, and tested it by calcining in an iron spoon in the fire: about 90 per cent. was dead, inert matter. So don't buy guano unless you know it is right. Sulphate of ammonia and dissolved bones will give all there can be in guano, and they are at least tolerably free from adulteration. As to runners, I think it the best plan to cut them all off and procure any new plants that may be required from another district. If soil is "far from light," it is sure to be benefited by the addition of cinder-ash, sand, or charcoal, and, in fact, anything that can be procured; but ground that refused to perfect carnations, and yet sent geraniums into too vigorous growth, is, I should think, lacking in phosphates, and they can be best supplied by bone meal or dissolved bones. Geraniums are rather capricious, I know—blooming profusely at times, while running to succulent stems and foliage at others; but with two-thirds good loam and one-third rotten manure from an old hotbed, with just a sprinkle of sand, they ought to do well. Without an analysis of the soil it is

not easy to suggest a remedy; but I will venture an opinion that "Lady Gardener" would do well to give her garden a dressing of plaster of Paris or gypsum, and if it is sulphate of lime from the gas-works, it will probably do better than either. So far as the soil is concerned, agriculture and horticulture are reduced to the condition of a science, which is nothing more than systematised knowledge. The soil must contain certain ingredients, and the "proof of the pudding" rests in the skill of the gardener. This "reply" is so long, that I think I ought to apologise; but I hope the subject is one that interests your readers, for there is, to my mind, no pleasure in life equal to a good garden.—SAML. RAY.

[60680.]—**Field Magnets.**—All makers of dynamos endeavour to run the armature in the most intense part of the field. What we suppose you mean is why makers do not design dynamos with salient in preference to consequent poles. The reason is that there is really very little difference between them, and the question becomes a matter of mechanical convenience. The ordinary horseshoe magnet is very efficient, and on account of its shorter magnetic circuit would certainly be superior to one with true salient poles. If you cannot understand the diagrams of drum armature winding, get some wire and wind a small model with a few coils, and you will soon get into the more complicated forms.—S. AND E., Coventry.

[60687.] — **Screw-Cutting.** — CORRECTION.— Please accept apologies for a stupid error in former reply to this query, by which the trains of wheels are given wrong way about.—NEPHESH.

[60690.]—**Wood Carving.**—What do you mean by common ornaments? A knife, with joiner's gouges and chisels, will serve for many purposes if you sharpen them well. The best amateur carver of my acquaintance uses none else. Get a common Swiss bracket and copy it. They are cheap and nasty enough, but will do for a first lesson; but above all things, your tools must be sharp. As a trade, the carving of common ornaments is one of the worst paid, but that a joiner or a cabinet-maker should be able to add a final grace to his work by carving is highly desirable, while few pleasures are equal to that of cutting a kindly piece of wood with a keen tool.—W. A. S. T.

[60693.]—**Trigonometry.**—

$$\text{Tan. } 2\,\phi = \frac{2 \text{ tan. } \phi}{1 - \text{tan.}^2 \phi} = 0{\cdot}1723$$

Hence $2 \text{ tan. } \phi = 0{\cdot}1723 - 0{\cdot}1723 \text{ tan.}^2 \phi$
and— $0{\cdot}1723 \text{ tan.}^2 \phi + 2 \text{ tan. } \phi = 0{\cdot}1723$

Dividing both sides by 0·1723, we obtain—

$$\text{tan.}^2 \phi + 11{\cdot}60766 \text{ tan. } \phi = 1$$

Solving this quadratic equation, we find—

$$\text{tan. } \phi = 0{\cdot}08552$$

With reference to the second part of the query, since— $1 + \text{tan.}^2 \text{A} = \text{sec.}^2 \text{A}$

we have— $$\frac{2 \text{ tan. A}}{1 + \text{tan.}^2 \text{A}} = \frac{2 \text{ tan. A}}{\text{sec.}^2 \text{A}}$$

$$\therefore \log.\left(\frac{2 \text{ tan. A}}{1 + \text{tan.}^2 \text{A}}\right) = \log.\ 2 + \log.\ \text{tan. A} + 10 - 2 \log.\ \text{sec. A}$$

or since—

$$\frac{2 \text{ tan. A}}{\text{sec.}^2 \text{A}} = 2 \text{ tan. A.} \times \cos.^2 \text{A} = \frac{2 \sin. \text{A}}{\cos. \text{A}} \times \cos.^2 \text{A} = 2 \sin. \text{A} \cos. \text{A} = \sin. 2 \text{A}$$

we have—

$$\log.\left(\frac{2 \text{ tan. A}}{1 + \text{tan.}^2 \text{A}}\right) = \log. \sin. 2 \text{A} - 10$$

—J. E. GORE.

[60700.]—**To Draughtsmen, &c.**—Having to divide a straight line must imply that you have an equally long edge regarded as sufficiently straight; and so it seems the well-known method, Fig. 1, can hardly be improved. It needs only two compass-openings, one to strike the two arcs C and D of equal radius, and another to mark off along the lines from A towards D, and B towards C, one less than the number of parts you require. For dividing circular arcs, it is plain that whatever divides an angle will do. The taper lazy-tongs, Fig. 2, will do this, if their pivots at the large ends and crossings be perforated. There is no necessity for the bars to taper, but it makes them shut up neater. They should be of horn, to be used comfortably. Eight bars like this will enable you to divide any arc or angle into 3, 5, or 7, and so into any multiples of these numbers by one another, their powers, or the powers of 2. The compasses can only bisect arcs or angles; and hence it was held for 2,000 years, from Euclid's time to that of our contemporary Gauss, that the only divisions they could make of a circle were into the powers of 2, and the product of each of these into 3, 5, or 15. But Gauss proved algebraically that we can divide it into 17 or 257, or 17 times or 257 times any of those numbers. Seven is impossible, and every square or cube of other numbers than 2 and its powers. After all, the old-fashioned "sector" would seem the most royal road to division of either straight lines or circles, especially as it has, or used to have, a scale of polygon sides, from 6 up to perhaps 20. But the following are the only divisions of the circle possible by compasses; and the number of openings necessary for each, with or without a straight ruler (r). Where I put no r

FIG. 1.

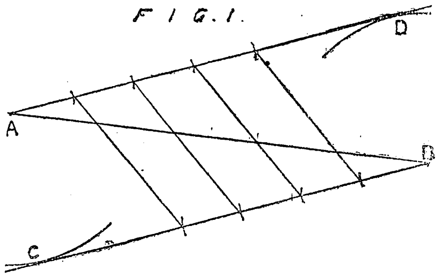


FIG. 2

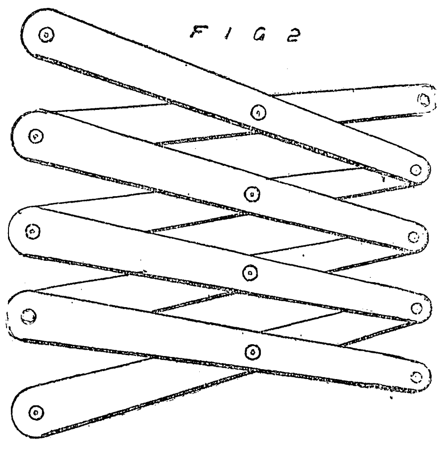

the use of the ruler will not save a single opening, and in all cases it is best avoided, as a source of error to which circles are never liable. In the new divisions discovered by Gauss, I cannot be sure that 9 are the fewest openings needed, only that 9 suffice.

Mascheroni, in his very useful "Geometria del Compasso" (which ought to be Englished), sometimes used unnecessary openings; three, for instance, to divide the circle into 24, which only requires two. The lazy-tongs (Fig. 2), which I believe are patented for this purpose, are the only means I can see for dividing any random angle or arc, not commensurable with the circle. But "Workman" speaks of dividing a circle, a much commoner problem; and for this, especially when the number, like his, would require an instrument of as many as 20 bars, I think I can suggest something better. Suppose a deep beam-compass, the beam at least 1in. deep, crossed by certain notches, to one or other of which the movable leg can alone be applied and screwed, instead of sliding. The whole length, from the fixed leg to the circle-marker being called 1, or radius, or cho. 60°, the notches are to be at the lengths of chords, like these—

Cho (180° ÷ 7)	Cho 7(180° ÷ 23)	Cho 5(180° ÷ 37)
180° ÷ 9	7(180° ÷ 25)	9(180° ÷ 41)
3(180° ÷ 11)	5(180° ÷ 27)	11(180° ÷ 43)
3(180° ÷ 13)	3(180° ÷ 29)	15(180° ÷ 47)
3(180° ÷ 19)	(180° ÷ 31)	15(180° + 49)

The divisors are either a prime number, or the square or cube of a prime; and each multiplier the number by which the divisor differs from the nearest power of 2. Now, to divide a circle (even into an odd number), first bisect it; then set off one of the above chords, and your circumference will be in two unequal parts, one of which will give the required points by mere bisection. Thus, for 9 parts, your chord cuts off 20°, which reduces one semicircle to 160°, or 4 of the parts required; for 13 your chord cuts off $1\frac{1}{2}$, making with the other semicircle 8 parts. A notch for any divisor composed of unequal factors, as 21, would be useless, as dividing the circle into 3 and 7 gives all the points. In bisecting, by the way, the use of the ruler does save one compass-opening of every two.—E. L. G.

[60700.]—**To Draughtsmen, &c.**—I am obliged to the correspondent who replied to my query last week; but his reply scarcely covers the ground of the query, which was not so much for information how to divide—as I can myself divide entirely to my own satisfaction—but, for a certain purpose, I wish the instruments and methods employed by others described with as much detail as possible. "Nephesh" says step it out with dividers; but how would the draughtsman who knows all about arithmetic and trigonometry proceed in setting dividers to proper distance? And how the illiterate mechanic on the two problems I set in my query, always provided the draughtsman and mechanic are provided with the modern and improved instruments?—WORKMAN.

[60704.]—**β 63 and P. XX. 177 Delphini.**— The principal measures of 1 Delphini, β 63, are—

De. 343·4 : 0·84″ : (4n). 1874·92. 6·0, 8·1mags.
β. 345·4° : 0·88″ : (3n). 1880·19. 6·4, 7·9mags.

It is a difficult object to see with a reflector. Some of the later measures of P. XX. 177 are—

Hall. 211·6° : 0·49 : (2n). 1879·73.
β. 211·5° : 0·51″ : (1n). 1880·61.
Eng. 211·9° : 0·40 : (6n). 1883·47.
Pe. 208·4° : 0·58 : (5n). 1883·63.

Both 1 and P. XX. 177 Delphini are probably fixed. Under the best circumstances Dawes was able to see a notched elongation in P. XX. 177 with a power of 600 on Mr. Bishop's 7in. Dollond, but he never divided it. Perrotin gives the distance of Σ 2491 as 1·277″ in 1883; the angle has increased a few degrees since 1828. The distance of 2 Vulpeculæ is 1·857″ according to six nights' observations by De. from 1874 to 1878; the magnitudes are unequal. β says of it: "The companion is a minute point, and lost in the rays of the larger star [with 6in. refractor] unless the definition is very good. De's mags. are 5·7 and 9·7; colours white and ashy olive or ashy blue. I suppose that "the triple 6968 Lyræ" in "Bramley's" query is a misprint for B.A.C. 6468 Lyræ.—H. SADLER.

[60705.]—**Dutch Language.**—I don't know any English-Dutch books; but perhaps the books used in the schools in Holland for learning English would do. If you like I will get you some titles of those books. If you want any further help I shall be glad to assist you.—HOLLAND.

[60705.]—**Dutch Language.**—If private study, try systems of "Thimms," 24, Brook-street; "Prendergast's Mastery," Longmans and Co.; "Monteith's," Cassells; and "Hossfield's" (at one time, if not now, at 96, Charlotte-street, Fitzroy-square, W., with branches). I believe they have all written for the above language. If classes, try those at the Birkbeck, City of London College, &c. See lists at some of the foreign booksellers (see Kelly's Directory), such as David Nutt, Strand; Williams and Norgate, Henrietta-street, W.C.; and A. Siegle, 110, Leadenhall-street. — BREAM'S BUILDINGS.

[60706.]—**American Medical Law.**—I am afraid all the American States are now following the English example, and recognising no qualification to practise medicine but those granted by themselves. The bogus universities are now blown up, and a genuine examination called for. Three years is the usual curriculum for medicals; but in many (as in France) an M.R.C.S. could get off with one year. As to the opening for a histologist or pathologist, I cannot give the querist any encouragement, for the simple reason that lately, when I spent some years in the great histological schools of Vienna, Strasburg, and Berlin, I found ten Americans for every Englishman at work there. —B.Sc., Plymouth.

[60707.]—**Dynamo.**—TO MR. BOTTONE.— Unless the resistance of the field-maget coils is enormously greater than that of the armature, the machine should work better with the wires coupled up in one continuous length than in parallel arc. The best proportion between outer circuit, armature, and field-magnets is: circuit, 1; armature, $\frac{1}{20}$; field-magnet, 20; or, what amounts to the same thing, the resistance of the armature must be $\frac{1}{20}$th that of the outer circuit, while the field-magnet coils should be 400 times that of the armature. But I am afraid you have joined up the wrong ends of the field-magnet coils.—S. BOTTONE.

[60708.]—**The Wimshurst Machine.**—As I have been engaged during the last twelve months trying various arrangements of electric machines, you, as well as others, may profit by a little advice upon the making of such a machine, so as to combine economy with efficiency — and nothing beyond the skill of an amateur. The method described by Mr. Bottone on p. 100, No. 1123, would certainly result in wobbling discs, and these anything but parallel to each other. If it be desired to make the machine after this pattern, the bosses

"must" be first bored completely through, then fitted with brass tube, and then turned up truly upon said tube. As to how the holes in the standards could be made and kept accurate enough to insure any reasonable amount of parallelism, must be left to the ingenuity of the operator. No, sir; if the object be to avoid boring a hole in the glass, mount each disc upon a separate axle. I find the following a very handy arrangement. The discs are of ordinary window glass, picked as flat as possible. I have previously described in these pages how to test it; but out of some dozens I only came across one bad plate, so that this is scarcely necessary; these are 19in. diameter, the mahogany bosses being $2\frac{1}{2} \times \frac{7}{8}$, affixed as already described by me, and which leaves nothing better to be desired. If when mounted the sharp edges be ground off by means of an old setstone, whilst the plates are revolving ("slowly," or you may break them) so much the better. The frame is of deal, having two coats of shellac varnish. The base measures $30 \times 17 \times 1$in., and has at each end, underneath, to prevent warping, a piece glued and screwed measuring 2×1in. Two standards, each $18 \times 4 \times 1$ are mortised into base at $3\frac{1}{2}$in. from the edge of one of the longest sides of the base and central. On top these are dovetailed to take a piece of inch stuff 8×4 for the bearings to rest upon. For the sake of ornament these standards may have, say, $\frac{1}{2}$in. cut out of edges next to the glass, so as to show the appearance of a column, and all edges chamfered off; at the back, we must let in a piece to carry the driving wheel. This is glued and screwed to the base-board, and is $8 \times 8 \times 1$, which also stiffens the standards. To finish these off we can glue around their bases little pieces of any ornamental moulding. The main spindle is made of a piece of iron gaspipe, say $6 \times \frac{5}{8}$ when turned truly, and upon one end of this is tightly fitted and soldered a brass face-plate, say $2\frac{1}{4}$ diam. by $\frac{1}{8}$ at outer edge running down to a neck of say $\frac{1}{2}$in., having four screw-holes to fasten it to the brass on disc, and enable same to be adjusted so as to run as truly as possible. Before turning up this piece of tube it is advisable to make a tool, in order to rymer out the inside of it. Take a piece of round steel, or say an old file, upset one end so as to turn up slightly larger than will fit into the tube; turn $\frac{1}{4}$in. taper and $\frac{1}{2}$in. parallel, and file, say, eight flats upon it. Note: four won't answer, as they will stick in a groove where the pipe is closed together. Harden as hard as it will go when heated to a dull red, now get the pipe in a vice, and work this round by means of a tap-handle, and use plenty of grease, and all the tarry stuff will be removed, and a tolerably smooth surface be left. After the outside is turned, I carefully redden the tube, sprinkle it all over with prussiate of potash, and seeing that it is red, dip perpendicularly into cold water; then on with the faceplate, and turn it up. The bearings are of brass, $\frac{5}{8}$in. in breadth, and I have not yet split them in order to tighten up, although often used for several months past. The spindle turned to fit inside of this one is a piece of brass tube, with the least possible amount turned off it. It has a similar faceplate, but fastened upon it in the reverse way, and in cutting it to lengths we must allow for thickness of brass, faceplate, and glass, so as to let, say, 1in. project beyond the end of the iron spindle. Now, we must cut out two discs of mahogany to turn up to $3\frac{1}{4}$in. diameter by $\frac{5}{8}$in. Into one side of each we let a square plate of stiffish brass, say, full $\frac{1}{16}$in. thick; drill a little hole in each corner, and bore with a small sprig bit, so as to gently drive in four round brass tacks, and rivet them nicely, so as to keep the pulleys from splitting or twisting; bore them to fit as tightly as possible upon the ends of the two spindles; then stick upon a mandrel, and turn them up, and with a V-groove of, say, $\frac{3}{8}$in. so that they will take an ordinary piece of sash-line. Although mine are only fitted thus, I have had them on and off scores of times, and now only require to slip a single piece of waxed carpet thread in. When putting them on of course there will require to be a washer or two of cardboard between the glass discs to prevent them from touching. The driving-wheel is made of two pieces of deal with the grain reversed, each 1in thick, and turned, say, 9in. diameter; these are first glued and screwed firmly together, then a piece of brass tube is driven nicely into the centre, measuring 2in. long by, say, $\frac{3}{8}$ bore. We then place upon a mandrel, and turn it up with two V grooves the same distance apart as are the two others. Now we require a stud-pin to fit this tube, having a washer at front with a small sunk screw into the end of the stud to keep the wheel on, and at the other a small collar, washer, and nut, by means of which we can screw it firm to the piece of stuff which is let into the lower sides of the standards. We have previously fitted a suitable handle to this driving-wheel by means of a small spindle of iron, say, about $\frac{1}{2}$in. diameter, having a small washer or collar fitted on to a part turned a little smaller and then soldered, so as to prevent it from settling out of the perpendicular. If we drive this into a hole at 3in. from the centre within about $\frac{1}{2}$in. from the opposite side of the wheel, it will be quite firm enough. Now if we take a suitable length of sash line, make fast one end, and give it a good pulling to stretch it, then pass it under the driving, then over one of the small pulleys above, down again, and up to the outside one, with a twist in it this last time; mark the right length, open an inch of each end, shove these ends after dipping them into the paste-pot and dividing each into four parts, then wrap around with waxed carpet-thread, we will have one endless belt, which has not required to be re-tightened after the first slackening up which will probably take place, for many months, and although I originally attached a means for tightening it with a movable arm, I have since removed same as unnecessary and spoiling the symmetry of the apparatus. The neutralisers for the plate nearest to the operator are made of two pieces of small brass tubing: that upon the left hand slides up and down in a hole bored perpendicularly in the piece of wood which forms the table for the axle bearings, and as near the inner ends of the sectors as convenient, in order to lessen the wear and tear of the same. About $1\frac{1}{2}$in. of the top end is bent to a round angle, a piece of the fine wire off an old bass string of a violin, about 2in. long, is pegged into its end, and this is all the brush that is necessary, and if nicely adjusted it will not injure the tinfoil sectors for a good while, and then they are easily repaired, being easily affixed to the glass or shellac with ordinary paste having a little pinch of borax in it. It is quite unnecessary to fumble with shellac upon the foil. The right-hand one is a straight piece moving in a little cleat upon the side of the standard, and there is not the slightest advantage to be gained by connecting them in any more direct manner either to one another or to the axles. The real circuit of the machine I maintain to be that the electricity is discharged from the plates to the air as well as to the nearest conductor to the sectors after they have passed away from the brushes; that it is given off most freely from the sectors which are midway between each pair of brushes upon the opposite discs, and that if the air be tolerably dry it seeks to regain its point of departure from the said brushes and sectors by ascending the framing and the driving band—not as Mr. Bottone, as well as Mr. Wimshurst, and, I believe, all others appear to think, viz., that it is from one brush to that upon the opposite diameter of the disc. As a proof of my position I am willing to describe an arrangement of my own, which will yield as much electricity of the same tension as does Mr. Wimshurst's, that is, if the disc or discs be driven at the same speeds, because I am of opinion that the peculiar advantage of the Wimshurst machine is to be attributed to the fact that as the discs are going in reverse directions, they are really going twice as fast as one single disc with a fixed rubber would be travelling past same. This letter is becoming of unwieldy proportions, so I must conclude by saying that the brushes upon the outside disc are similarly attached to a piece of the same tubing, having each end bent to a suitable curve and fastened by a small screw at centre to pillar of wood like, say, an umbrella shaft, with a suitable base glued on, to screw on to the baseboard.—A., Liverpool.

[60708.]—**Wimshurst Machine.**—The spindles in my machine are not insulated from one another, since the wooden uprights are not insulators. The thin brass does not hold on the glass nearly so well as the tinfoil. The mode recommended for attaching the bosses is far better than any I have yet tried, and I can strongly advocate its use. The simplest way of testing plates or jars is to warm them, so as to get them nice and dry, and then try whether they become fairly electrified when briskly rubbed with a piece of dry, warm silk.—S. BOTTONE.

[60710.]—**German Universities.**—To enter one of these, a German student must possess an equivalent to our degree of M.A. An Englishman, however, is admitted on his producing (1) any degree of any English university; (2) Evidence that he is a member or matriculated student of any English university. The idea that a student can benefit by joining a university where the teaching is done in a language he is unacquainted with, is so ridiculous that it needs no comment. After one year's hard work at the language in the country, a student may be able to follow the lectures with profit to himself. The fees are very moderate, and living also for those who know the language and live as the Germans do. Lecture fees vary from 10s. to 60s. per semester, according to the hours lectured in a week. Any aufhörer or outsider can hear the lectures on payment of the fees; but this does not count for a degree.—B.SC., Plymouth.

[60713.]—**Fire Hose.**—Two inch hose should be large enough for $\frac{3}{4}$in. jet, and very little, if any, benefit would be derived from $2\frac{1}{2}$in. hose. Can you not increase the pressure in main? It is decidedly low.—T. C., Bristol.

[60715.]—**Motor for Canoe.**—If you are about to make the pump yourself, I would suggest your trying the form I sketched in No. 1102, May 7. This pump, modified to have inlet in front of canoe, outlet at back, would send your boat forwards or backwards, according as you turned handle one way or the other. No air-vessel would be required, as this pump throws and draws twice for each revolution of the handle.—SILKE.

[60717.]—**Hot Dynamo.**—TO MR. BOTTONE AND MR. EAVES.—This dynamo is radically wrong. There is either a short circuit somewhere, or else the brushes are in the wrong position. The addition of more lamps would cause less current to go round the field magnets (if it is wound as a shunt machine), and this would make matters better for the dynamo. But a properly wound, and especially properly commutated, machine should not feel the difference of the lamps so much as yours does.—S. BOTTONE.

[60717.]—**Hot Dynamo.**—TO MR. BOTTONE AND MR. EAVES.—The heating of the machine is caused by an excess of current in the F.M. coils. There are three ways of remedying this fault. First, by using lamps of less voltage; secondly, by winding more wire on F.M.'s; thirdly, by inserting a resistance in series with the field coils and increasing the speed of the machine. Putting more lamps in circuit will not improve matters, as the current in the magnets would have to be slightly increased to compensate for the drop in E.M.F. caused by the increase of current in the mains. The heating of the commutator is caused by the sparking; the commutator, perhaps, wants turning up. The brushes of these machines want adjusting with great nicety, as the neutral space is rather small.—S. AND E., Coventry.

[60718.]—**In Beat.**—I think if "Amateur" will place his watch on a small box of rather thin wood, it will increase the sound; and also, if placed on a sheet of glass, such as a looking-glass, it makes the beat more distinct.—E. C. F.

[60724.]—**Circular Saw Bench.**—Belt and suitable pulleys, say 3in. and 24in., with 4in. saw, would be the best and simplest plan; and you can't beat treadle, unless you have someone to turn for you.—T. C., Bristol.

[60724.]—**Circular Saw Bench.**—You do not say whether you are to use your saw for cross-cutting or ripping; if for cross-cutting or ripping very short lengths, you may do with a speed something like 1,000 revs. per minute; but if you are to rip more than 12in. lengths, you cannot keep up such a speed. What I advise you to do is to put a pulley 9in. diameter by 3in. broad on the saw spindle; fit up a countershaft and mount on it a flywheel, belt pulley 18in. diameter, and crank handle, the crank arm, say, 12in. long, put on a light 3in. belt, and you have a very good manual circular saw; I have tried quick speed and failed. With a slow speed and a well-trimmed saw one man can keep up a steady drive, cutting 3in. deep. A very simple method of testing the slow-speed principle is to put a flywheel and crank handle on the saw spindle and drive direct, same as turning a grinding-stone.—SANDY DUNN.

[60724.]—**Circular Saw Bench.**—The usua plan is by a heavy flywheel and cord or strap to a pulley on the saw spindle. Assuming the speed of the fly to be one revolution per second, which is about the rate at which we work a lathe, a 3in. pulley, with a 30in. flywheel, gives 600, and a 2in. pulley 900 revolutions, with which I think "J. C. D." would be wise to be content. Increase of speed is decrease of power; and in any case it is hard work, though certainly extremely convenient, as the pulley must not project above the table. A 5in. saw will give a 2in. cut, which is all that is here needed. As to gearing with cogwheels, I should like "J. C. D." to try one of those novel saws, patented by the Britannia Company, who have an agent in Liverpool. Theoretically the thing is all wrong, but practically no saw can touch it. The speed is tremendous, and the power is stored up by the heavy fly and gear-wheel, and is given out economically. It will continue to cut long after you cease to treadle, and that is what no other saw can or will do.—O. J. L.

[60725.]—**Insulation.**—1. All wires should be evenly and tightly covered with silk. 2. When wires are double-covered the second layer should be in the opposite direction to the first. 3. There should be some little difficulty in getting the covering off either with knife or file. 4. Silk is used as an insulator because it is much more reliable as an insulator than cotton; also we can get a greater number of turns in a given space with silk-covered wires.—VINCENT.

[60725.]—**Insulation.**—I should doubt whether any general rule could be laid down, as the amount of insulation required depends upon the intensity of the current employed, as the thickness of a water-pipe must be proportioned to the pressure it will have to resist. External circumstances must also be considered—e.g., a wire running along a stone wall would require much less insulation than

one traversing a metallic surface; as, in the latter case, the increased tendency of the "fluid" to escape would have to be counteracted. Silk is frequently substituted for flax because its vastly superior insulating power enables a less clumsy covering with equal effect to be used. In certain electrical apparatus (as in induction coils), it is requisite that not only the secondary wire should be well insulated, but that the numerous successive coils should be kept as close to the core as possible; a silk-covering instead of a flax one facilitates this. No. 16 cotton, as being the coarser, would naturally give a better insulation, though No. 50 might be amply sufficient for the purpose required.—B. HARCOURT.

[60725.]—**Insulation.**—The difference in degree of insulation is simply to fit the wires for different purposes, and depends upon the E.M.F. of the current the wires will have to carry, and the degree of conductivity of the air or other substance that is to surround the wire. Thus, if the wire is for electric bells in a house where they (the wires) will be out of the way, not exposed to wet and never touched, single cotton covering will do, because nothing is likely to disturb the wires, and the E.M.F. of the current they will have to carry is extremely low, being only that of one or two Leclanché cells, or about 3 volts. But if there are many wires, so that they cross each other, and two or more strands have to be put under one staple, then it becomes expedient to use a rather better covering, as indiarubber and double cotton covering. And if the wire is to be carried under the sea, where it will be surrounded by water, which is a partial conductor, and will be exposed to considerable rubbing and cutting from rough rocks, &c., while the E.M.F. of the current will be high, a very heavy insulation is used. Similarly with telegraph lines, dry air is the best of all insulators, and in dry weather the wires, though bare, being fastened on telegraph "insulators" specially made for the purpose, remain insulated from the earth and from all other wires, although the E.M.F. is sometimes pretty high, and even in wet weather, though some of the current is lost, enough is preserved to do the work, which requires a very little quantity of current. Silk is often used, especially for the finer wires, because it makes a very close and firm covering, one layer being as good as two of cotton, and takes up less than half the space. Hence it is much used for small magnets, where, owing to magnetic laws, it is desirable to get the desired quantity of wire into the smallest possible space—e.g., to lie as close as possible to the cores of an electro magnet. Cotton is sometimes used for small wires. It is a matter of cheapness principally; but where the gauge becomes very small, silk is used on account of its greater flexibility, enabling it to be laid on tightly, with less risk of breaking the wire. Large wire, as for dynamo-winding, is generally used cotton-covered, to save expense. The insulation of electric-light wires depends on the situation where they are to be placed. If in the floors of a dry, well-built house, where the E.M.F. will not exceed about 100 volts (which means, in other words, all incandescent lamp installations), and the linesmen who lay the wires are careful, experienced hands, who understand taking precautions where wires cross or touch, comparatively light insulation is safe, providing the wires are properly connected, as they always should be, through fusible plugs or cut-outs, without which the best insulation is not safe. Where the situation is damp, however, as under the roofs, or underground, or in the open air, proportionately better insulation should be used, the exact quality being a matter of experience, upon which every electrical engineer decides for himself. For E.M.F. up to 100 volts and heavy currents, as for electric lighting, tinned wire covered with a plaited or woven cotton covering soaked in G.P. does very well for most ordinary indoor work. Wire from which the insulation can be stripped with a dig of the thumb-nail is not really fit for any purpose, not even for electric bells. There is no exact rule for determining insulation. In large contracts there is sometimes a clause specifying that when completed the installation shall show an "insulation resistance" of so many megohms. In electric lighting, 80,000 ohms means a good installation.—E. CONRY.

[60728.]—**Steel or Iron Tubes.**—The following is a most reliable rule for ascertaining the thickness of tubes to stand internal pressure. Let D equal the diam. of tube in inches, P pressure in pounds per square inch. Thickness $= \frac{D \times P}{11{,}000} + \cdot 125$. In your case it will be $\frac{12 \times 90}{11{,}000} + \cdot 125 = \frac{27}{275} + \cdot 125 = \cdot 098 + \cdot 125 = \cdot 223$, or about $\frac{7}{32}$ thick. The divisor for steel is 13,700. In the second question we shall have $\frac{16 \times 30}{13{,}700} + \cdot 125 = \frac{24}{685} + \cdot 125 = \cdot 035 + \cdot 125 = \cdot 16$, or about $\frac{5}{2}$ thick.—ENGINEERING, MANCHESTER.

[60728.]—**Steel and Iron Tubes.**—If you allow 2 tons per sq. in. section for single riveted joints it will give a factor of safety of between 5 and 6 for iron. For 12in. tube strain = 20 × 12 × 1,080lb., say $\frac{1}{2}$ ton, which would give 4in. sectional area—that is, $\frac{1}{8}$in. plate. For the 16in. steel tube strain is only 16 × 30 = 480lb., and bare $\frac{1}{20}$in. is strong enough, But if weight is no object, have it stouter, as there is very little more labour.—T. C., Bristol.

[60726.]—**Cement.**—I should think indiarubber dissolved in spirits of wine would do.—E. CONRY.

[60729.]—**Driving Belts.**—We don't allow anything for belts slipping. We have a belt transmitting 250 horse, and if it slips we tighten it, or apply a good coating of castor-oil on the back of the belt.—B. HELME.

[60730.]—**Turning Small Cylinder.**—Why not fasten to face-plate with bolts, and bore it out at one cut with a flat drill, put through a steady, fastened in the hand-rest, and drill held with a wrench. The drill would bore better if a piece of hard wood were screwed on each side of the drill, a little larger than the hole, and then you would get a clean cut.—B. HELME.

[60730.]—**Turning Small Cylinders.**—Scarcely possible to do it true enough by hand tools alone. Your best plan will be to chuck it on the face-plate, and start the bore truly by hand tool, and then put a packed bit through by means of back poppit. A packed bit is one having pieces of wood screwed on each side of a flat bit, and all turned to size parallel, then part of wood cut away for room for cutting. Of course the wood must be removed for hardening the drill.—T. C., Bristol.

[60731.]—**Drill for Small Work.**—The cranked lever is forked; forked ends slotted; upright tube slotted; slots engage pins on loose collar in the tube. Loose collar is between a fixed collar (on the spindle) and the drill-holder. Thus, raising or depressing collar-pins (by means of lever) raises or depresses drill-spindle. A portion of my drawing did not "come out" in the engraving; hence it is not quite clear. Don't understand how you could have been about to make one before my drawing appeared. Any further particulars if you advertise your address.—SILKE.

[60732.]—**Whitworth's Millionth Machine.**—You will find a sketch and description of this in "Shelley's Workshop Appliances." Briefly, it is as follows:—A rigid bed, with ends carried up to form headstocks, in which slide square bars with ends at perfectly right angles. The bar at, say, the left is moved by a screw of 20 threads thick, having a large wheel on end divided into 250 parts, so that a movement of one division moves bar $\frac{1}{250}$ of $\frac{1}{20} = \frac{1}{5000}$ of an inch. The other end has also a screw of 20 to the inch; but the large wheel is a worm-wheel of 200 teeth driven by a worm also furnished with a large wheel, or index, divided into 250 parts, so that a movement of 1 division of this wheel advances the bar $\frac{1}{250}$ of $\frac{1}{200}$ of $\frac{1}{20} = \frac{1}{1000000}$ of an inch.—T. C., Bristol.

[60733.]—**Take a Post-Card.**—I wish this query had not been put. But the answer is evident—that there is nothing to prevent the fraud suggested, and the exact weight is immaterial, provided it ranges between the weight of ordinary penny coins.—T. C., Bristol.

[60736.]—**Small Light Magnets.**—To "A.G.G."—I don't know what you infer by "raise"; but a 6in. smooth flat file cut off to the length required, and the tang end used as the pole, after being magnetised, lifted, on contact, a ring $\frac{1}{4}$lb. iron weight. These I have used years ago for telephones. I should observe that the tang end was ground down until it was square—about $\frac{1}{8}$in.—VINCENT.

[60736.]—**Small Light Magnets.**—You do not say through what space you want the magnets to act, and that is all-important. If not more than $\frac{1}{4}$in., then little electro-magnets would do—say, cores $\frac{1}{2}$in. by 3in., insulated with paper or a very thin bone, or wooden reel, and wound with, say, eight layers of No. 30 to make sure, and worked by about 8 volts and $\frac{1}{4}$—$\frac{1}{2}$ an ampère; but I do not see how you can dispense with a battery, unless you use a magneto-machine, and wind your magnets with the finest wire you can get, which would mean a lot of trouble.—E. CONRY.

[60740.]—**Universal Chuck.**—The square jaws with triangular notches are prevented from travelling on their round centre pins by two screws, which pass through the jaws and screw into the casting that forms the base of the centre pin, which casting is moved in or out by the main screw with right and left-hand threads as described. The heads of these two screws are shown in the drawing referred to by "R."—DYNAMITE.

[60741.]—**Mensuration.**—Half-close the open mouth of your vessel by a flat half-moon. Place it with this vertical; pour in water up to the level of axis; then tilt it till the liquid ceases to touch the half-moon, and make a mark where its surface meets the slant side.—E. L. G.

[60742.]—**Propeller for Launch.**—It is a very difficult thing to give a rule for the diameter of a propeller, and the area of blades can only be determined by actual experiment. A small propeller totally immersed is much more efficient than a large one, the blade of which is above the surface of the water; in which case the rule holds good that the diameter of the propeller should be less than the draught of water. It must, however, be borne in mind that the diameter should bear some relation to the power of engine, for if made too small it will not absorb the power developed by the engine. In your case, you cannot very well do with one less than 10in. diam., having a pitch of 20in. Total area of blades, 50 square inches.—ENGINEERING, MANCHESTER.

[60743.]—**Cast-Iron Piston Rings.**—In using cast-iron rings, the piston is generally made in two pieces—viz., a block and a broad ring called the junk ring, which is fastened to the block by means of set screws, the packing ring being between.—ENGINEERING, MANCHESTER.

[60743.]—**C.I. Piston Rings.**—The piston has a "junk ring" fastened by set-screws, which can be removed for insertion of rings. You can draw them by light hammering the insides with ball of hammer, but if not experienced may break them. If there is room put a circular spring of steel behind the rings.—T. C., Bristol.

[60744.]—**Question in Dynamics.**—If his ascent was gentle and regular, though swift, there should not be any motion; but in practice, the jerking of the string would probably add to his weight a slight momentum sufficient to start the other mass, when slow motion would result, accelerating gradually through momentum.—E. CONRY.

[60745.]—**Lead Valley.**—Your best result will be to rip off the slating and put in all new lead; but if you wish to try other ways, you may cut out the old lead, leaving 2in. off it from edge of slate, and turn the same up as flashing to cover edge of new lead. I would recommend you to employ a good practical workman to lay the new lead, who will be the cheapest man in end of time.—SOMERSET LAD.

[60745.]—**Lead Valley.**—Cracks in sheet lead, whether in flats, gutters, or valleys, should never be repaired with solder. Hear ye this, oh ye plumbers! Solder only makes matters worse, by making tight and immovable the lead, which should be free to move—to expand in sunshine, to contract with frost. I always use bicycle cement. I had, some years ago, a most troublesome lead gutter, which was always going wrong. The bicycle cement was used, and I have heard nothing of it since. A new gutter, badly constructed in the country, with too shallow a drip, let the water in badly. This drip was solidly covered up with bicycle cement, and the job was a perfect one.—SOUTH KENSINGTON.

[60746.]—**Valves.**—We have one of Hopkinson's full-way valves 2in., and is working with a pressure of 100lb.; it has been working nine months, and there is not the least indication of leakage. I scarcely need mention it can be opened full and closed again in two seconds, with a handle 6in. long.—B. HELME.

[60750.]—**Glass for Fish-Tank.**—I made a fish-tank, and it held about nine gallons. I used 28oz., and it seemed quite strong enough.—B. HELME.

[60752.]—**Turning Balls.**—Rough them all out as near as possible to templates, but a little large. You must now have a piece of steel for each size, say $\frac{1}{8}$in. thick for large sizes, and $\frac{1}{16}$in. for small sizes; now drill the steel with, say, $\frac{3}{8}$in., $\frac{5}{8}$in., 1in., $1\frac{3}{8}$in., and 2in. holes. If you have only 25 to do, the same piece of steel may be drilled out in successive sizes; you must harden the steel, and keep the sides ground flat. If you chuck the balls and apply above tool, either above or below, and keep moving it in all directions, as well as the balls, it will act as a scraper and make them true.—T. C., Bristol.

[60758.]—**Small Launch.**—You could not do so without considerable alterations. You might be able to manage by half-filling firebox with asbestos wool, and arranging apparatus to continually inject petroleum in a fine spray. In one of the London illustrated papers about two months ago (I think the *Pictorial World*) there was an article about the method employed on the Russian steamers on the Caspian, which burn petroleum. You might pick up something useful from this.—E. CONRY.

[60759.]—**Aniline Dyes.**—To S. BOTTONE.—Rince the flannel alternately and repeatedly in rather strong ammonia water, and then in plain water. Repeat this rinsing until the colour does not reappear when a few drops of vinegar are allowed to fall on the flannel.—S. BOTTONE.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

QUERIES.

[60761.]—"**Performance Guaranteed.**"—Will some of our astronomical correspondents or makers of specula inform me through the medium of "Ours" if the remark "performance guaranteed," used so often in advertisements, really means, and is intended as, a guarantee that the specula will give a moderate-sized star's image, in a focus with the highest power, as a very small disc, almost a point, accurately round, with one or two narrow rings of light?—ENQUIRER.

[60762.]—**Engine Flywheel.**—I have purchased a secondhand steam-engine, with a stand or frame in the shape of a letter A, the flywheel working on the top of the triangle. The size of the flywheel is 5ft. 5in. in diameter, 4in. wide on face. The rim or edge is also 4in. thick, with 6½in. cylinder and 18in. stroke, which makes the cylinder longer than they are in general. Would not that give extra power? What would be the power? Would the flywheel be too large to drive a pulley wheel 8in. diam. for a 30in. circular saw and smaller one? Only one saw would be worked at one time. What distance would be required between saw pulley and flywheel for belt?—STEAM ENGINE.

[60763.]—**Clarionet.**—What is the cause of the following weak note in my clarionet? F sharp with the top key open and the four top holes closed. E natural below and G natural above blow quite strong, but F sharp is almost dumb. I have carefully cleaned the instrument and passed a rag through every hole, but cannot cure it.—FLAVIUS.

[60764.]—**Pyrophorus.**—I endeavoured last winter to make this remarkable firework. I tried the two following recipes: (1) Take three parts of saltpetre and one of flour (or sugar), calcine first the saltpetre in a ladle to a black mass; triturate this and mix the flour or sugar with it; place the mixture in a hard bottle, and set it in a small but clear fire till a bluish flame appears at the neck; cork it up with a chalk stopper and let it cool gradually. (2) Dissolve 1½oz. acetate of lead in water; dissolve separately ½oz. of tartaric acid and water, mix; a white cloudy precipitate falls—tartrate of lead; collect this on a filter and dry. Put this in a bottle and proceed as in No. 1. With both methods I had only partial success, the fire coming up so slowly even in the open air, and after a few hours refusing to come at all. Will some chemical friend show me the cause of my non-success, and also, if there are any other methods, describe them? I want to put the pyrophorus in a powder flask with a cut nozzle, to use as a pipe lighter. Some years since I bought one which was too "wick," as it went off like a rocket. It resembled a "ladies' tormentor" in appearance.—GEORGE BELL.

[60765.]—**Area of Sewer.**—Would any reader kindly say how to get the following? Let it be granted that a sewer of 2ft. in diam. is sufficient to remove the sewage from a population of 5,500—what size of sewer would be required for a population of, say, 10,000 or 15,000?—STUDENT.

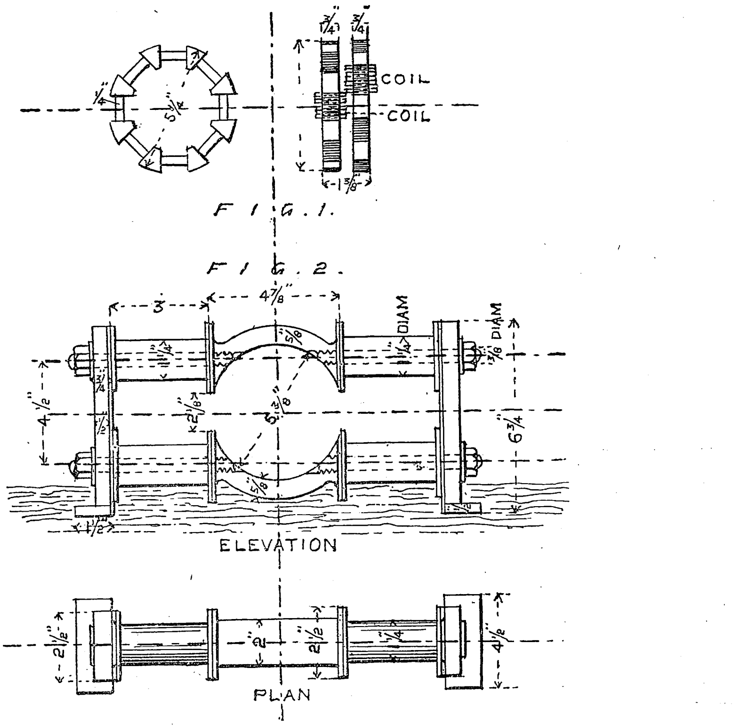
[60766.]—**Hooping Furnace.**—Would any of your readers oblige me with information, or a sketch, on this subject, as I am about to build one? It is for heating tires, 1⅝in. by ⅝in. and 2½in. by 1in.—A. L. K.

[60767.]—**Exploding Gas by Electricity.**—Will any of our correspondents kindly answer the three following questions? I want to explode gas in a cylinder by electric spark from an ordinary Bunsen cell. Will a Bunsen do for this purpose? What should I use to insulate the wires where they pass through side of cylinder? What should the terminals be made of?—VOLTA.

[60768.]—**Glass Taps.**—Would some glass-blower kindly say how glass taps (small ones) such as are used in chemical apparatus, are made? I mean a tap, say, in the middle of a tube of about ⅛ or ¼ dia. Could an amateur make them by aid of a good blowpipe and bellows, or are they all moulded?—G. W. A.

[60769.]—**Capell Fan.**—Will some of our readers give me a sketch of the Capell fan (double inlet), made by Heenan and Froude, Birmingham?—H. S. H.

[60770.]—**Field Magnet Winding.**—TO MR. BOTTONE.—Will you kindly help me in winding my dynamo? Some five or six years ago I designed a dynamo as per sketch before I was aware of the importance of using wrought iron. The armature is made up of two cast-iron rings with eight recesses in each for winding coils in (Fig. 1), placed side by side, with the coils of the one in advance of the other, as in a Burgin machine. These coils, sixteen in all, are connected up as in a Gramme ring, and their respective resistances are as follows: 0·18, ·15, ·16, ·15, ·14, ·16, ·16, ·16, ·17, ·20, ·17, ·18, ·17, ·15, ·16, ·19 of an ohm. The field



magnets are built up, as shewn (Fig. 2), of castings, all annealed. The bobbins, A, A, A, A, are cast separately for winding, and are fixed by a wrought-iron core running through them and bolting on the end pieces. This is as far as I have got. Now I should like to finish it. I don't care whether it is series or shunt wound; but I should like to get 12 volts and as many ampères as I can, say, at from 1,000 to 1,500 revs. Will you please tell me what quantity of wire to put on the bobbins and the B.W.G.? I think that on the armature is 20 or 22 B.W.G. I don't want to alter or make new field magnets if I can help it; but if you think it absolutely necessary, will you give me a sketch of what you would propose? I want to light as many 5-candle lamps as possible.—ANXIOUS.

[60771.]—**Ventilation.**—I am about to build a house at a cost of about £650, and am much perplexed as to ventilation, which I wish to be as perfect as may be. My architect, who is supposed to be a good one, suggests building shafts alongside chimney drafts, and putting Sherringhams in near ceiling for exhaust use, without providing for inlets. I think this is wrong altogether. I would not trouble you for your opinion, but I have read several works on subject which seem to treat the question in a very tentative manner, and all of which are rather opposed among themselves. Will you kindly advise me or indicate where I can find the knowledge I require? I estimate the ground floor will contain 10,000 cubic feet, the first floor 9,500, and the attics 5,000, and am inclined to ventilate as follows: (1) Have doors, windows, and fireplaces as near on one side of rooms as possible; (2) Have openings in wall opposite fireplaces, close to ceiling, connected with pipes, which shall lead from various rooms to chimney flue, and be conducted in cluster up same to outer air, the cluster of pipes being heated by pipes conveying hot water to bath room, if necessary, the hot-water pipe to be twisted or prolonged; (3) have an "Eagle" gill stove in hall to supply warm fresh air to house; (4) have ventilating stoves in living rooms. If above is a reasonable plan, I want to find out what size the pipes from living rooms and bedrooms should be—whether to supply Tobin tubes for use in summer instead of hall stove. In connection with this must be considered the probable consumption of gas, which would be in living rooms 24 cubic feet per hour.—ARTHUR ALABASTER.

[60772.]—**Running Lathe Backwards.**—When using the grindstone on the lathe, and turning it from me, as I have no guide, the driving chuck always loosens out and thus jams the stone. If this can be avoided, I shall be glad to hear.—BEGINNER.

[60773.]—**Legal Query.**—Will some legal correspondent kindly answer the following? I have been practising as an assistant to a surgeon for some years (though not qualified). Can I practise and call myself an oculist on my own account? Am fully conversant with the work and have all instruments.—OPTOTYPI.

[60774.]—**Heating Conservatory.**—"T. C., Bristol," described a boiler a few weeks back for heating small conservatory with hot-water pipes. Would he oblige by sending a sketch of same, as I have a small place I wish to heat by hot water; but I cannot understand how the boiler is made in the shape of the letter T.—C. W.

[60775.]—**French Wire or Sheet Gauge.**—There is a gauge called the French gauge, the numbers of which run as follows: 0000, 000, 00, 0, 1, 2, 3, 4, 5, 6, &c. I estimate Nos. 0, 3, 4, 5, 6 to be 75, 66, 63, 60, and 55 hundredths of a millimètre each respectively. Can anyone tell me further particulars of the gauge, and if it is based on any standard measure? A correct list of the numbers and their respective equivalents in French or English standard would oblige—B.

[60776.]—**Boiler.**—Would any practical reader kindly inform me whether a boiler 12ft. long by 3ft. wide would drive a 6 H.P. engine? It is an old-fashioned dish-ended boiler, with a straight flue underneath it. Would it be better if the flues were built round the boiler, and could I get extra power out of it by so doing?—WILLING TO LEARN.

[60777.]—**G.N.R. Locos.**—Will some railway correspondent please tell me how the G.N. manage to get such a powerful blast or exhaust on their suburban tank engines? Also whether they adopted any special arrangement of motion or valve-gear to get a pair of 19in. cylinders in between the frames of their large goods-engines that have cylinders of that dimension (19 by 28)? Are the valves underneath?—A REGULAR READER.

[60778.]—**To Mr. Bottone.**—I want to light a room 9ft. by 2ft. with electric light. I got a 2½c.p. lamp from Messrs. Shippey Bros., and made a Dale's granule battery of 4 cells, outer 8in. by 6in., and porous cells 7in. by 2in. Solution for outer, 2 parts of saturated bichromate of potash to 1 part of hydrochloric acid, and for porous, 1½oz. of salammonic and 1oz. of hydrochloric acid, and filled up with water. I cannot get the lamp up to its full power with that battery. If we substituted chromic acid for bichromate of potash, would that be any improvement? If not, what is the best battery for the purpose?—SCOTIA.

[60779.]—**Electric Gas Lighter.**—Clarke's patent Nos. 2,229 and 245. Will someone kindly inform me what kind of battery this lighter contains, and the best means of charging same?—F. G. B., Bristol.

[60780.]—**Wimshurst Electric Machine.**—I have constructed one of these machines, 16in. in diam., according to instructions in number 1123 of the "E.M." (the first number I commenced getting), and I cannot get it to work with good results—in fact, sometimes will not work at all. I shall thank any reader for instructions as to how I can work it so as to get a shock similar to that obtained from the medical or shocking coils, if such can be obtained. I see it stated in Messrs. Dale's price list, that the same results can be obtained from these machines as from the induction coil. Being a novice in electricity, I would like to know if there is a book obtainable on the application of these machines, with experiments, &c.? Any information will help me.—ELECTRIC.

[60781.]—**Corundum for Aluminium.**—We will be greatly obliged if any of your numerous readers will inform us if corundum of the following analysis would be suitable for the manufacture of aluminium:

Alumina (Al_2O_3)	68·90
Oxide of iron	4·62
Silica	25·65
Lime	·49
Magnesia	trace
Water of combination and undetermined	·34
	100·00

The analysis has been made by Bernard Dyer, F.C.S., F.I.C., of 17, Great Tower-street, London.—RICHARD BAKER AND CO., Mica and Mineralogical Brokers, 9, Mincing-lane, London.

[60782.]—**The Mustel Organ.**—Would "Country Solicitor" kindly say where the specification (French) and drawings of this referred to in one of his letters are to be obtained?—D. B. P.

[60783.]—**Battery Power.**—I wish to light by bichromate battery eight 10c.p. 12-volt glow lamps; size of cells, 12 by 8. Two carbon plates 12 by 6, and one zinc 12 by 6 to each cell. How many cells will it take, and whether lamps are in series or parallel arc?—LES DENTS.

[60784.]—**Locomotives.**—Having just returned from a visit to Scotland, I would ask one or two questions. What description of safety-valve is used on domes of North British engines in place of Mr. Drummond's Ramsbothams? What is the speciality of whistles on new Caledonian engines? The larger size has the sound of a horn. Is it a usual practice to employ bank engines on North British Railway going up to Galashiels and from Hawick, as I have seen done? So much for Scotland. Can any reader who remembers the 1851 London Exhibition give particulars of the "Liverpool" and "Folkestone" therein exhibited? I am reminded of these by the mention of "Cornwall" in last issue, which, if I remember rightly, was also shown. Besides these and

"Lord of the Isles" I forget what engines were there.—SETRACH.

[60785.]—**Induction Coil.**—What length of spark can be obtained with an induction coil as described in Mr. Dyer's book by using, say, a 6-cell Bunsen battery? I should like to ask some questions concerning induction coils; but as they will not be interesting to other readers, I should be glad if someone well acquainted with induction coils would give his address and allow me to do the questions direct to him.—HOLLAND.

[60786.]—**Colouring Photographs.**—To "B.Sc." OR OTHERS.—Would any reader kindly state clearly how photographs are tinted? What kind of colours—water or oil? What is the special preparation which renders the professionally-tinted photos. so clear and transparent? How is the colour applied to make it hold? Any wrinkles in the manipulation, &c., will oblige—BENSON.

[60787.]—**Earth Connection—Leakage.**—C M L is a battery circuit. At the point M a connection is made to earth. What is the result? Please explain by reference to potentials and resistances.—GAR.

[60788.]—**Botany and Geology.**—Will some fellow subscriber recommend me some books suitable to study for the Honours Examination in botany and geology of the Science and Art Department? I have obtained an advanced certificate in each. I believe that it is necessary to know the recent advances and discoveries in these subjects, and for this the ENGLISH MECHANIC is invaluable. Are there any other periodicals that would be useful? Any hints as to mode of study, &c., would be acceptable. Is Bournemouth a good locality for practically studying these subjects?—PYRAMID.

[60789.]—**Coil.**—I have constructed an induction coil of the following dimensions: Bundle of soft iron wire, ⅝in. by 7in., two layers of No. 16 double c.c. for primary, 1lb. of No. 36 silk-covered wire for secondary coil. Each layer is most carefully wound and varnished. Will anyone say how many square feet of tinfoil the condenser ought to contain, and what length of spark I ought to get with two bichromate cells, each containing two carbon 6in. by 3in. plates, zinc between.—WILLIAM WILD.

[60790.]—**Pressure on Model Boilers.**—Will some reader of practical experience kindly tell me what pressure an iron boiler 10in. long, 5½in. in diam., cylindrical in form, iron 1-12in. thick, will safely stand, the boiler being riveted and brazed; internal firebox with tubes screwed on? I don't understand how "Glatton" gets his 24lb. per sq. in. in No. 60548 Replies to Queries.—PUZZLED.

[60791.]—**Tangent Galvanometer.**—Will Mr. Bottone please tell me the correct way of calculating the strength of current in ampères with the above? Say in Birmingham you get 20° deflection with a coil 12in. diam. and magnet 1in. long, what is the current flowing? Only one coil of wire in ring.—CARNWORTH.

[60792.]—**Achro. Objective.**—I want to try my hand at a 4in. achro. objective, and would thank anyone for a little instruction. What are the best books to study? Where to get suitable glass (as I have no idea where to get it)? I have been practising with British plate. What focus best suited for the dia. and a (simple, as I am not far advanced in algebra) formula for finding the curves to produce achromatism? Dia. of cast-iron tool and polishing tools? What are best materials for grinding? I am using emery for coarse and fine grinding, then powdered pumice stone, and polishing with rouge. Can I do better with any other powder? An answer to 60611 would oblige—YOUNG MECHANIC.

[60793.]—**Wine Cellar.**—I wish to mature some whisky, brandy, and rum. Will some of your correspondents kindly say in what kind of casks this is best done for each respective case, and if I can do so by buying at maker's prices and placing in "bond"? Also, which whiskies make the best "blend"? I understand a good safe whisky is made up of not less than equal quantities of three distilleries. Which three are recommended?—EDINBURGH.

[60794.]—**Brazing.**—Having broken one of the teeth of one of the change-wheels of my lathe, I should be very thankful to some reader if he could instruct me. How could I get it put back again? Is there some method of brazing it together?—YOUNG TURNER.

[60795.]—**Studio.**—Will any reader inform me the best way to range the glass in my studio to get the best maximum of light for taking negatives? My studio is 14ft. by 8ft., walls 6ft. in a close back yard, ends running east and west. What sort of roof is the best?—A STUDENT.

[60796.]—**Spark from Wimshurst Machine.**—Would Mr. Wimshurst kindly let me know how to get the longest spark from one of his influence machines? I think he has mentioned "smallness of Leydens" for length of spark. The machine I refer to has 24in. discs and 20 segments. Also, would a condenser do instead of Leydens, and, if so, would not larger sheets of foil in condenser give denser sparks?—T. E. F.

[60797.]—**Bookbinding.**—Would some correspondent tell me the right way to prepare and use glair in bookbinding? I wish "Practical Bookbinder" would give us an article on plain finishing, as I believe it would prove very acceptable to a good many amateurs like myself.—A. ADAMS.

[60798.]—**Fixative for Drawings.**—Can anyone inform me how to make a varnish with methylated spirit to use with a spray-producing apparatus for fixing drawings? What kind of gum is soluble in methylated spirits?—D. S.

[60799.]—**Srew-Cutting.**—Suppose it be required to cut a screw 1¼ diam., and a nut to fit it, what size should the hole in the nut be before cutting thread in it? Any suggestions as to the sizes of other holes for other diams. will be thankfully received. The above is for a Whitworth thread.—POOR SCREW CUTTER.

[60800.]—**Ratepayers' Association.**—Will any reader be kind enough to tell how to start a ratepayers' association, and how to work the affair? What power will it have when established? Any information relative to the above will oblige—RATEPAYER.

[60801.]—**Mechanical.**—Will some of our electrical experts give the relative resistance between armature and field magnets for plating dynamos, series and shunt?—T. L. H.

[60802.]—**Spanish.**—Some of your corrrespondents recently recommended Foerster's "First Spanish Course on Ahn's system." This I got and studied. Could they now kindly oblige by saying what books they would recommend for further progress to one who has no facilities at present for attending classes or obtaining personal instruction?—PARALOS.

[60803.]—**Wheels and Axle.**—I should be glad if some kind reader would tell me, through the columns of this paper, how to make a good pair of cart wheels, and also how to put them to run well? I have heard of the axle fixed and the arms set by cross lines, but have no notion how it is done, being a young country wheelwright.—A NOVICE IN THE TRADE.

[60804.]—**Burgin Armatures.**—Can any reader of our valuable journal give me the probable cause and how to prevent the armature coils fusing in this dynamo, which have given me much trouble? The wires appear to get hot generally in the centre of the coil, and the heat increases until eventually the cotton covering burns, and insulation breaks down entirely. Is it possible to be brought about through opposing currents in the armature due to the collectors not set on the commutator in the proper position—i.e., one brush having too much lead, or both making contact with too many segments at the one time? The armature in question is used for arc lighting, and for some time I thought the fault was caused by excess current in the circuit through a lamp burning close-arc, or entirely out; but I have known it occur when the lamps were all steady and burning.—MILLER.

[60805.]—**Accumulators.**—I have a shunt-wound dynamo, giving 60 volts and 18 ampères, charging 26 E.P.S. Company's S type accumulators. I find that when starting to charge them (though I never allow them to get below 2 volts apiece), the engine goes at a certain pace; but when fully charged (that is, when the acid gets milky) the engine goes faster. How is that? Ought not the engine have more work to do when the accumulators are so full (the E.M.F. being more than 2 volts apiece while in that state)? A gas-engine is used with governors tied down, so that speed ought not to alter, unless load is taken off. Also, what is about the internal resistance of these cells?—P. LONDON.

[60806.]—**Storage Battery.**—Is it possible to make a storage battery capable of transportation after charging, say, from London to Edinburgh?—those that I have seen being accumulators only and not at all adapted for moving. It seems to me one might be constructed somewhat in the manner of a sawdust or paper-pulp cell, which might, with ordinary care, be moved from the place of charging to where it was required to be used. If this is practicable, will any of "ours" kindly give me details as to construction, &c., of a battery capable of lighting a 600c.p. arc lamp of the ordinary type for a period of two hours for once charging? Also, what would be the utmost limit of time between charging and using?—AMPERE-METER.

[60807.]—**The Mersey and Severn Tunnels.**—What are the respective depths below Ordnance datum at the level of the rails in the lowest points of these two tunnels? I have examined the accounts of them in several engineering papers, but in none is there any reference to Ordnance levels. From aneroid observations, I estimate the depth at the bottom of the former to be approximately 110ft.; but should be glad to know the exact figures; also the heights of the various stations on the Mersey Tunnel Railway.—PARALOS.

[60808.]—**Small Gas Engine.**—Would any of "our" "knowing ones" kindly give me the following information? I am thinking of making a small gas-engine during the winter. What are the best proportions of gas and air to explode? What length of stroke and size of cylinder most suitable for about ½-man power? How is the noise of explosion deadened as in the Otto? Shall be grateful for any suggestions and sketch of design. Prefer upright type.—S. S.

[60809.]—**Electricity Accumulator.**—Can I be informed through your columns if electricity can at present be stored so as to be commercially practicable—that is, what might be the size and cost of an accumulator or store to hold, say, sufficient to work an engine of, say, 10 horse-power, for, say, 100 hours, or for lighting purposes to light a railway station for, say, 100 hours, or, if the above is too large an amount, say the half or third of the above?—G. A., Glasgow.

[60810.]—"**Relief" Map of the Moon.**—I am anxious to make "Relief" representations of several of the principal lunar formations separately or in groups, and would much value practical help from "F.R.A.S.," Mr. Elger, or any of "our" many competent correspondents. Please say what material and scale would be best to employ? Also give typical example of how to reduce depth and extent of craters, &c., to scale adopted. I am sure the information would be of general as well as of special interest.—S. R. C.

[60811.]—**Solar Shadows.**—Would "F.R.A.S." be good enough to inform me whether and when any attempt has been made to ascertain the shape of the solar shadows at the equinoxes at the Equator? If the earth revolves on an axis, and the sun is in a direct line with the Equator in March and September, ought not the shadow from a perpendicular staff to be perfectly straight, first westward, then eastward, of such perpendicular, so—

(Sunset) W ——— . ——— E (Sunrise)

If it is not so, what shape is it, and why? And, indeed, I need not limit it to the equinoxes; but when a sphere revolves on an axis before a stationary light, all shadows from upright staves should be absolutely straight. Am I right or wrong?—JOHN HAMPDEN, Balham.

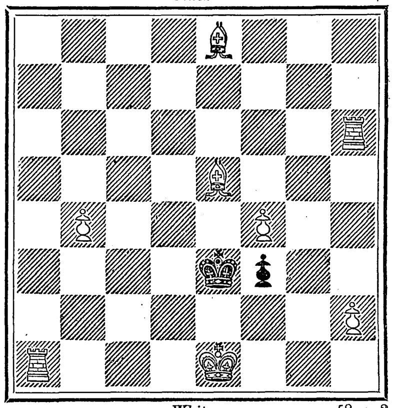
[60812.]—**Paper-Making.**—Can anyone assist me to a better understanding of following par.?—"A plan for rendering paper as tough as wood or leather has been recently introduced on the Continent. It consists in mixing chloride of zinc with the pulp in the course of manufacture. It has been found that the greater the degree of concentration of the zinc solution, the greater will be the toughness of the paper. It can be used for making boxes, combs, for roofing, and even for making boots." At what stage of paper-making is the chloride of zinc added, and in what proportions? And much oblige.—PAPYRUS.

CHESS.

ALL Communications for this department must be addressed to J. PIERCE, Langley House, Dorking.

PROBLEM MXV.—BY A. BOLUS.

Black.



White. [8 + 2

White to play and mate in three moves.

SOLUTION TO 1,013.

White.	*Black.*
1. R-Q B 8.	1. Anything.
2. Q, R, B, or Kt mates.	

(Fourteen variations.)

NOTICES TO CORRESPONDENTS.

CORRECT solutions to 1,013, by I. M. Brown (hackneyed), Black Pawn (easy; also a dual), J. Mackenzie, A Beginner, A. Bolus, Isca, and Avon; to 1,012, by A. Bolus, Thomas Quilliam, M. Blackmore (fine and difficult), G. A. A. Walker (exhibits beautiful chess), and I. M. Brown (fine specimen of the attacking style).

J. MACKENZIE.—In your attempt at 1,012, where is the mate if 2. $\frac{}{\text{P-Kt4}}$?

CAISSA.—Your solution to 1,006 is correct, but it was published some weeks ago.

G. A. A. W.—We congratulate you on having solved a very difficult problem under adverse circumstances.

I. M. B.—Many thanks for report, which we have found interesting. We are glad to find the Leeds Chess Club so flourishing.

WHITE PAWN.—You have failed again, but do not be discouraged. If 1. R-K 3, 1. R checks, and there is no mate. You must always give Black his best play.

A. DEAN.—You have put in your solution 1. Q-Q B 7; but it *is* there!

J. P. TAYLOR, J. Slater, C. J. Lambert, and W. H. S. Monck are thanked for problems and games. *The Wanderer* received with thanks.

THE result of Tourney B (solutions in two and three moves) is as follows: A. Bolus and the Hon. Sec. Leeds Chess Club bracketed, equal for first prize, Pierce's "Chess Problems," number of marks, 225; 3, M. Blackmore, 208, Miles's "Chess Problems and Poems"; 4, G. A. A. Walker, 201, J. P. Taylor's "Dot." The remaining competitors come in the following order: 5, G. T. Stringfellow, 166; 6, A Beginner, 150; 7, F. W. S., 120; 8, T. Quilliam, 110; 9, A. Dean and Link, 94.

THE problems which produced the greatest inequality were 1,005 and 1,009, which had more than two solutions; also 1,000, which had two solutions. It has been a pleasure to receive solutions from all these competitors, who have shown that no three-mover is too difficult to baffle them, and also that they fully appreciate the beauty of a problem when there is any there.

THE result of solution Tourney C will be given in our next. We hope to be able to start new Tourneys on similar lines in the course of two or three weeks.

A COLLEGE for the training of actors has just been founded in Berlin in imitation of similar institutions at Paris, St. Petersburg, and Vienna.

THE number of Freshmen who have been entered at Cambridge this October is 938, being the largest entry ever recorded. Trinity College heads the list with 197.

THE entire length of railroads of the world up to the end of 1884, as recently published by the Prussian Minister of Public Works, was 291,000 miles, an increase of 27 per cent., or over 60,000 miles, during the preceding five years. Of the entire length, very nearly one-half is that of the American Railroads, mainly in the United States.

AN amusing incident occurred last week at the Colonial and Indian Exhibition Aquarium, where a remarkable raven from the Isle of Mull is now on view. On being fed, it is the habit of this bird to hide the remnants of its repast in various parts of its habitat, and exhume them when prompted by hunger to renew the meal. One day a rat invaded the spot, and commenced to excavate for the hidden articles of consumption. Enraged at this proceeding, the raven fell upon the rodent, and gored it to death after a severe struggle on both sides.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, Oct. 27, and unacknowledged elsewhere :—

JAS. MURRAY.—Medical Battery Co.—Leroy and Co.—W. Grimshaw.—F. A. Moilliet.—R. Hughes.—C. D.—W. Saunders.—T. E. Espin.—Taube.—Northern Counties.—Motion.—F. G. F.—J. Riley.—C. J. Tahourdin.—Geo. Hunt.—Engine Driver.—G. Bowron.—A Fellow of the Royal Astronomical Society.—A Socialist.—S. H. Smith.—J. C. W. Kershaw.—Hendon.—E. J. L.

W. J. JOHNSON. (The query has been inserted, and we must refer you to the replies, if any appear. The query omitted to mention the pressure and number of revolutions, and possibly may remain unanswered in consequence. You will not gain much by increasing the length of stroke, as such engines do best when running quickly under high pressures. We had no idea that you were working at such a pressure as 60lb.)—WALLACE NEWLAND. (In the surface condenser the steam is brought into contact with the surfaces of a number of tubes, through which cold water is drawn, and the steam, being condensed, can be returned to the boiler. The other form of condenser has a jet of water thrown into the steam, and the latter is thus mixed with the sea-water. It is usual to fit the surface condenser so that a jet can be used when advisable.)—DIVES. (See index to the last volne, under head "Fire-grenades.")—A READER, F.D. (A Bunsen cell consists of an outer jar, generally stoneware, containing a porous pot, which latter is occupied by a stick of carbon immersed in the strongest nitric acid. The porous pot is surrounded by a slit cylinder of zinc, immersed in dilute sulphuric acid. If you procure a list from Mr. Blackwell, 26, Chapel-street, Liverpool, you will find the various sizes of parts suitable for battery construction.) — ALKALI. (The sand-blast is used for many purposes, but mainly for abrading surfaces, such as glass, instead of grinding or clouding with acid fumes. It is also used for sharpening files. See Vol. XXVII. pp. 314, 437, or Vol. XVI. p. 235.)—READER, Weaver-street. (The query about the result of an irresistible body coming into contact with an immovable substance was inserted many years ago, and an apparently satisfactory answer is that the larger substance has a hole made in it. The question is, of course, nonsense.)—G. COLE. (The year 1900 will not be a leap year. Easter Sunday will fall on April 15, unless the modern system of arranging the movable feasts is altered by that time.)—VALENTINE. (There are several books about gasworks; but you do not specify what information you require. See "Common Sense for Gas Users," published by Crosby Lockwood and Co., Stationers' Hall-court, E.C. 2. It all depends on how much the burner can pass. A standard consumes five cubic feet an hour, but the majority of burners consume about three cubic feet.)—T. M. (Get the iron thoroughly clean by pickling in acid and rubbing with sand, and then immerse in a bath of molten zinc which is covered with a layer of salammoniac to prevent oxidation.)—C. (Barlow's "History and Principles of Weaving," Sampson Low and Co., may suit; Bischoff's "Woollen and Worsted Manufactures," Smith, Elder, and Co., is another. 2. For marine engineering, Sennett's work, published by Longmans, or Reed's "Engineer's Handbook," T. Reed and Co., Sunderland.)—W. G. M. (As you have been a subscriber for so many years, you will remember the explicit instructions given in the notes on plumbing. Lead-burning has, however, been frequently described; but see Nos. 912, 913, 915.)—A. B. (Nothing is better than air drying—that is, natural seasoning; but there are several processes nowadays with both dry air, steaming, &c.)—FLAVIUS. (The query must be more definite; but by searching the indices you will find references to devices of the kind.)—F. F. F. (What is it you mean—one of the screw copying presses, or one of the glue and gelatine "graphs," as they are termed? If the latter, answered many times; if the former, you must find out where to buy the castings, or the press will cost a great deal more than you could buy it for.)—E. P. B. (Neither well rounded or pointed; the essential thing is to have it set properly. Mitchell's F is a good pen for inking in.)—LECTURE. (Send the question to *Bicycling News.* We do not think such statistics have been published, and we cannot spare space for the insertion of such a query.)—E. S. MARRINER. (We have given details of the latest improvements in telephones, which you will find by reference to the indices.)—G. W. MOORE. (Perhaps you mean the mechanical telephone. If so, see No. 1061, p. 447.)—J. K. (If the plates and other parts are in good condition, it would be worth while having it "formed" if you have any use to put it to.)—MECHANIC. (The method of sharpening horse-clippers was described in No. 875, p. 410. They are usually taken apart and rubbed on a strong glass plate with fine emery and oil.)—S. H. (You will find many recipes for secret inks in back numbers, but possibly the best is a solution of chloride of cobalt, which appears when the paper is warmed and fades as it cools.—A NOVICE. (By fitting a layer of swansdown over the vent holes. The swansdown is usually glued to a bit of board, so that it can be readily removed when all the noise of the instrument is required.)—HENDON. (It is scarcely likely that any work of the kind has been published, as the sale would not pay for the printing; but you will find information in the back volumes, and in "Amateur Handicraft," published by Kent and Co., Paternoster-row, E.C.)—SHINY BOOTS. (If you refer to the "Answers" last week, p. 184, you will see that a correspondent is referred to Dircks's "Perpetuum Mobile," published by E. and F. N. Spon, 125, Strand. It gives illustrated descriptions of most of the schemes for producing perpetual motion.)—E. N. M. (The defects are probably in the medium used between the lenses, but you must get a practical man to examine them.)—J. W. BUTTERFIELD. (Diving is altogether peculiar work, which demands not only special but constitutional aptitude. If you can procure a medical certificate that you are capable of undertaking such work, Messrs. Barnett and Foster, 25U, Eagle Wharf-road, New North-road, London, might be able to put you into the way of finding employment.)—JOHN J. GILBERT. (We shall not be able to publish the lectures, nor do we suppose the lecturer would like them published. 2. We do not think any of our readers are offended by such remarks.)—SAN REMO, VAN EYS. (Yes, decidedly. An electro-plater who has any amount of work would find it advantageous to use a dynamo. If you look through the advertisement columns, you will see announcements of dynamos for sale suitable for plating purposes.)—AMBER. (Certainly it matters—the object is to get a length of wire on as closely as possible to the core; but there, rough winding would be altogether unworkmanlike.)—S. B. T. D. (The only book is "Back Numbers." Read an article in No. 1061, p. 447, and see if you grasp the principle.)—SOLAR RADIENCE. (You do not appear to see that a full answer would involve a gratuitous advertisement, and if we permit that in one case, we ought in fairness to allow others the same privilege. Procure the catalogue of published books issued by G. Philip and Son, 32, Fleet-street.)—WINDERMERE. (Just so; but then it is simply impossible for us to repeat what has been already given, merely because a reader has not the opportunity of referring to back numbers. If the information is worth having it is worth looking for, and it can be found in recent numbers. 2. We quite understand your question about asbestos cloth instead of porous cells, and refer you to previous answer, p. 184. 3. If the battery cells are required for a hot country, better have them properly lined with lead, or use glass or stoneware. 4. As to the ecclesiastical or legal opinions, as there is already so much difference, and they are really of no interest to a hundredth per cent. of our readers, why should we encumber our columns with queries which "five bishops" cannot agree to answer definitely? They are questions which only the highest courts of the realm can finally answer.)—L. (We gave the recipe for transparent cement on p. 182 as we found it; but we think with you that the proportion of chloroform to caoutchouc is much too small.)—15 YEARS' SUBSCRIBER. (If it makes you feel sick, it is decidedly injurious; but why heat petroleum spirit to 100° Fahr. and then breathe the vapour? If you are referring to a lamp, then that is not properly trimmed.)—D. BOOTH. (There is an article on "Japanning and Japans" in No. 860; and an article on "Blacking Optical Work" in No. 944.)—INQUIRER, G. J. J. (Mere guesswork without an opportunity of examining the walls. Try water-glass both outside and in, or cement or tar the outside.)—BOOTES. (Boiled oil 1 pint, bees-wax and yellow resin 2oz. each Melt together. That is liquid or semi-liquid. A dubbin is made by boiling 2lb. of black rosin and 1lb. of tallow in a gallon of cod, train, or whale oil.)—PHOTO. (Good glue or copal varnish will probably answer. 2. Depends on the nature of the recording instrument. Those having a continuously revolving drum produce a flowing curve. See Redier's barograph in No. 999.)—MOTOR. (You will find the information you require in back numbers. A gas-engine properly constructed and properly looked after, does not require to "be stopped and the cylinder cleaned often.")—B. (Boiled water is the best remedy for gout when distilled cannot be obtained; but a still can easily be arranged or an ordinary glass chemical retort be utilised for the purpose.)—W. G. MORGAN. (Australia or New Zealand, we should think. If you have had experience in the work, no doubt any of the agents for the Colonies would forward your application to the right quarter, or you could write direct to the locomotive superintendent of any of the lines. The Agent-General for —— (mentioning the colony), London, will be sufficient address.)—R. A. R. BENNETT. (No, we think not; but it could be managed by removing the tube and having a standard tube to take various kinds. Why not write and ask him direct?)—SOUTH COAST. (It could be done by carrying the flow-pipe up a sufficient height; but it would be troublesome and expensive. 2. Such a boiler is scarcely suited for the purpose. It should be a proper steam boiler to be safe.)—B., Dulwich. (Only in the Greenwich returns, we believe, for so many years; but try the library of the Royal Meteorological Society.)—W. F. P. (You do not say whether you mean waggon coupling, coach coupling, or brake-pipe coupling. If the first, no one can answer—not even the Americans, and they have made a good many trials. None has been adopted in this country. See index to last volume.)—INQUIRER. (Directions for polishing a ball-room floor were given in No. 1073, p. 148.)—TOM. (If you have not a lease, the landlord can compel you to leave by giving the proper notice, which appears to be a week, as you pay weekly. If the drain is in such a state that you talk of calling in the sanitary inspector, we should think you would do well to get out of the house and take one where the drains are in order.)—AN AMATEUR. (Sketches of model boilers in Vol. XLIII. pp. 63, 193; Vol. XLII. p. 346; Vol. XLI. p. 110; Vol. XL. p. 239; and so on through all the back volumes. Probably one illustrated in No. 1025 will suit you; but if you can see the back volumes you will have a large number to select from.)—S. (Mr. Wassell's papers on polishing glass specula commenced in No. 852, and Mr. Brashear's paper on making flats is in No. 883.)—A BEGINNER. (You will find it more economical to buy the porous pots.)—AN AMATEUR ELECTRICIAN. (You will find descriptions of most in back volumes; but there have been so many modifications, that it is impossible to say now without examination of a specimen. Surely those who sell them publish descriptions.)—BUILDER. (Better write the secretary, at 9, Conduit-street, W.)—VIBRATOR, F. L. STRIFFLER. (In type.)

CHARGES FOR ADVERTISING.

Twenty-four words	0	3
For every succeeding Eight Words	0	3

ADVERTISEMENTS in the SIXPENNY SALE COLUMN.

	s.	d.
Sixteen words	0	6
For every succeeding Eight words	0	6

*** It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions and in cases where the amount sent exceeds One Shilling, the Publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O.'s.

The address is included as part of the advertisement, and charged for.

Advertisements *must* reach the office by 1 p.m. on Wednesday, to insure insertion in the following Friday's number.

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve Months, Post Free to any part of the United Kingdom. For the United States, 13s., or 3 dol. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office Order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. JAMES W. QUEEN and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII. XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX., XL., XLI., XLII., and XLIII., bound in cloth, 7s. each. Post free, 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post free from the office (except index numbers, which are 3d. each, or post free, 3½d.).

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI., and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

OUR EXCHANGE COLUMN.

The charge for Exchange Notices is 3d. for the first 24 words, and 3d. for every succeeding 8 words.

Corn Mill, hand-power, by Nye and Co., London, quite new. Will take good Tricycle or Lathe.—Address, GEO. H. HEAVEN, 8, Oakland-road, Bristol.

Good Value Offered (cash or instruments) for all kinds of sound or repairable Scientific Appliances.—CAPLATZI, Science Depot, Chenies-street, near British Museum. Established 1862.

"Knight's London," "Timbs' Curiosities," 36 numbers, complete, good condition, cost 2s. each. What offers? Exchange or cash.—A. GORMAN, Hawthorn-road, Kettering.

Engine, horizontal, 1in. bore, 2in. stroke; silver Geneva Watch, good order. Exchange for small Lathe or Fretsaw, or anything useful to value 27s. 6d.—NEALE, 4, Silver-street, Kettering.

MICROSCOPICAL ADVANCES.—XIV.

By Dr. Royston-Pigott, M.A. Cantab., F.R.S., F.R.A.S., Memb. Roy. Coll. Physicians, Fell. Cambridge Phil. Society; formerly Fellow of St. Peter's College, Cambridge.

Solar Spectra emitted by Small Lenses.

HERSCHEL'S solar shutter-beam, described in No. XIII., is extremely inconvenient; in fact, quite unmanageable for systematic observations.

I beg now to allude to some interesting results arrived at in bright daylight, and without any shutter-hole in a darkened room:—

The researches detailed in the present paper were commenced in May, 1871. The results arrived at were largely obtained by using the microscope. Similar, but less brilliant and more scanty appearances, can be obtained with the telescope; but the very high power and ready adaptability of the former confers some advantages not offered by the latter. In both, however, the same principles are illustrated.

A cone of rays of small angular aperture, having the object-glass for its base in each case, engages the eyepiece, and emerges parallel, and the eyepieces are similar in each.

Peculiar facilities for studying solar spectra and their indications of aberrations and mechanical errors are also afforded. The focal plane of vision may be employed to examine the effects of the interference of complex cones of light of large angular aperture, at least twenty times larger than those observable by the telescope.

The discovery by the writer of an unsuspected residuary aberration in the best microscopes, described in the "Philosophical Transactions" for 1870, renders it probable that some such a residuum still remains in telescopes.

Eyepieces, abounding generally with spherical aberration, require also particular attention. I have repeatedly observed a fine state of definition completely blurred merely by a change of eyepiece of the same power which no mere focussing ameliorated, and which could be only corrected by a change in the convergent pencil passing through the objective intrinsically affecting its aberrations.

Another branch of such an inquiry is the nature of the definition of an organic particle under high powers; as every such research, such as the detection of the characteristics of diseased and healthy cells may be resolved into the power of the microscope to define a single organic particle. Such particles are generally brilliant and refracting spherules, and the errors of observation are unfortunately at present of a numerous kind.

On the Circular Solar Spectrum.

Experiment.—If a lens be so placed that its axis is coincident with that of the microscope, and if its principal focus formed by the solar rays be examined by an instrument of the highest quality, we shall find that minute slices, as it were, of the solar cone, present phenomena of rare beauty and order, dependent on the quality of the examining instruments.

Experiment.—If two plano-convex lenses be placed with axes coincident, a good many coloured rings may be counted, *but no black ones*. As soon as their axes become oblique the solar spectrum takes an intricate form, whilst the centre shows a brilliant cross. Very difficult to describe or represent by portraiture, but worthy of the highest photographic art, are all the forms developed.

In my former research I had observed a flame-disc in a darkened room. This disc presented two or three diffraction rings similar to those of telescopic stars, but much broader. The same method was attempted with the sun. Various objectives were employed to obtain a solar miniature of the sun's disc.

Plane mirrors, of glass, silvered at the back, entirely failed.

In order to form a pure and brilliant solar spectrum, it occurred to me to take advantage of the principle of total internal reflection from a prism. I then constructed a prism-heliostat, which, acting in sunshine, presented an aërial miniature of the sun of great splendour (almost as dazzling as the sun itself) for half an hour, without further adjustment.

The heliostat was furnished with a double convex lens of crown, the prism being of flint glass. Extra lenses could be applied so as to reduce the solar miniature from 1-40th of an inch to any required diameter. In some cases object-glasses and eyepieces were also interposed to receive the minute solar beam. The whole apparatus was rendered as achromatic as possible.

Received by an inverted object-glass of fine quality attached to the substage at a distance of 200in. from the heliostat, the original miniature could be again reduced. A theoretical diameter of sixteen-millionths of an inch was found convenient.

(*Phil-Transact.* 1870, p. 595:—

"Diameter of disc at prism 3 × sin. 30′..................	= 0·026
Diameter of miniature at 200in. reduced by 1-8th objective 1,600 times (16 millionths)	= 0·000016
Observed diameter of solar disc, exclusive of its jet black diffraction ring...............	= 0·00061

As 0·000016 is to 0·000061, so is 1 to 4 nearly, or the observed miniature disc was enlarged just about four times greater than it ought to be.")

To moderate the overpowering brilliance of such a spectrum directly viewed, neutral-tinted slides were at first used, or smaller discs formed by deep heliostatic lenses.

When this minute spectrum is viewed with a power of 1,000, the phenomena attending residuary errors, whether of achromatism, or spherical aberration, or mechanical construction, are demonstrated with so keen a severity upon the handiwork of man as to throw all other methods into the shade. An extraordinary number of richly-coloured rings of dazzling brilliance was now exhibited in the plane of the focal vision of the solar disc.

The most striking figure amongst so much effulgence was an intensely black (*jet black*) diffraction ring encircling the central disc. The appearance of the rings changed every instant with the slightest change of focus, and their tints indicated the nature of the "secondary spectrum."

Upon closer inspection my curiosity was excited by observing the shape of the primary central black ring, somewhat squared off, as though not consisting of one true black ring. I then found, by changes of eyepieces, length of body, and collar corrections, that it was composed of several *eccentric rings*.

In some cases the movement of the Ross collar adjustment produced two false central discs. Another glass gave four false discs in a deeper focus. A 1-16th was fitted with a water-immersion front; this now displayed two, each disc displaying its own diffraction system of rings. It was now necessary, then, to insure only one axis by using a simple plano-convex lens to form the miniature sun.

An extraordinarily fine ⅛th immersion, at first used dry, produced from the miniaturing lens a crimson solar disc, edged with deep black. Deepening the focus, with exceeding lightness of touch, the central disc became pearly white, set off prettily in its black setting, and a number of pale lavender, pale rose colour, and then brilliant circles of bright green, with intervals of orange red, and more outwardly circles of red merging into ill-defined black.

Upon water being introduced between the objective and a small piece of glass cover 0·003in. thick, the central solar disc appeared single, and bounded by a clear, sharp, jet-black truly circular ring. By lengthening the body, and using different eyepieces and stage lenses, at last the whole field was perfectly filled with forty-eight magnificent rings, glowing with exquisite tints, which vividly reminded me of Sir John Herschel's eloquent language on telescopic diffraction phenomena. The field was apparently 4in. broad.

If the stage or miniaturing lenses be used smaller and smaller, many of these effects are suppressed. When we come to diatomic beading, some, however, are still preserved and exhibited.

Three general features were constantly observed: the rings were seen either wholly or chiefly on one side of the solar disc—i.e., either within or without the focus, or nearly similar except in colour on opposite sides of the focal point.

If the rings were on one side only, a nebulous brightness occupied the other side, into which the solar disc suddenly resolved itself on a slight change of focus; but frequently this nebulosity assumed a fine-grained "engine-turned pattern." Occasionally two primary discs, each with its own system of rings, struggled for the mastery; and, on changing the focus, a chromatrope effect was produced by the expanding rings and their eccentric intersections, presenting extraordinary loveliness of colours.

In these researches a very near approach to achromatism was signified by the whiteness of the central disc, the blackness of the fine rings contrasting finely with the intervening rings, which were then of a very pale and yet brilliant lavender.

Destruction of spherical aberration appeared imminent when the rings still coloured were tolerably symmetrical on different sides of the finest focal disc with contrasting colours of the residuary spectrum. Mechanical errors were revealed by irregularity of marking and complexity of form.

I shall now venture to detail some of the particulars attending the circular solar spectrum formed by a small plano-convex lens transmitting a minute beam of sunshine from the heliostatic system.

Description of the Rings of the Circular Solar Spectrum produced by a small convexo-plane lens observed in the focal plane of the solar disc.

Coloured Rings.	Intervals.
1. Central disc, white.	Primary ring, jet black.
2. Pale lavender	Secondary ring, black.
4. Lavender	Third ring, black.
6. Lavender	Fourth, black.
8. Lavender	Fifth, black.
10. Pale rose	Sixth, dark red.
12. Bright green	Seventh, dark red.
14. Bright green	Eighth, dark red.
16. Bright green	Ninth, dark red.
18. Bright green	Tenth, black.
20. Dark orange	Eleventh, black.
22. Deep orange	Twelfth, black.
48. No record	No record.

A high-quality water-immersion was used with a piece of glass 0·003in. thick, attached by water to the front lens of a 1-10th objective, giving a power of 1,000 diameters.

A remarkable fact appeared. Each of these 48 rings, under a power of 1,000, measured by a Browning recording micrometer, appeared exactly of the same breadth.* The thickness of the primary jet-black dif-

* The 1-16½ thousandth of an inch.

fraction-ring corresponded exactly to the wave-length of the line F in Fraunhöfer's Spectrum—viz., 0·000406 millimètres, or 52,256 waves per English inch.

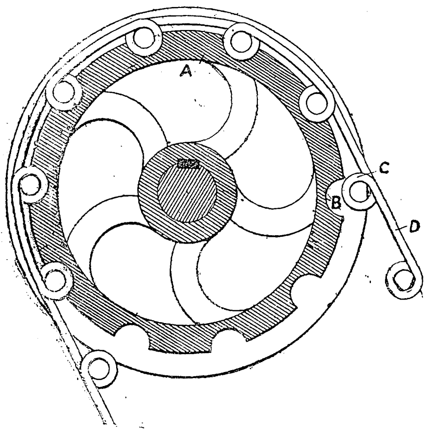
The precision of the construction of this fine glass was revealed by the use of a simple plano-convex lens, illuminated by a small pencil of solar rays. This speaks volumes for the use of diatomic lenses, such as have already been described in these articles. No one could have foreseen that an ordinary plano-convex lens of ¼in. focus supplies a most severely cruel test of the goodness of an objective; indeed, it seems doubtful to me whether any glasses in the world now extant can go through this ordeal without scathing its reputation. It is the action of the wavelets of light which here tests the glass.

In the next article I propose to deal with some of these exquisite revelations, giving drawings of results and the instrumentation.

(*To be continued.*)

STARLEY'S IMPROVED DRIVING GEAR.

UNDER the title of "Improved Means for Transmitting Motion between Pulleys or Drums," Mr. J. K. Starley, of Coventry, has recently obtained a patent for driving "bands" made of steel wire with coils. This invention



is designed to provide a substitute for the usual pitch chain (which, from the frictional parts contained therein, is liable to elongate in the pitch and so get out of truth with the wheel) or for the ordinary metallic bands, which are liable to break. The steel or other suitable wires or strips are coiled in one or more coils at intervals, and arranged to enter corresponding recesses in the pulleys or drums. The wire can be continuous or made in sections for the purpose of hardening the coils, such sections being coupled by suitable connections—such, for instance, as pieces of sheet metal gripping the ends of each opposite coil or pair of coils and riveted together. To assist in driving, pegs or studs may pass through the coils or through the couplings uniting them. Suitable recesses are made on the peripheries of the pulleys or drums for the coils and the wire to enter and where pegs or studs are used, transverse recesses may be made across or between the wire and coil recesses, according to the position of the pegs or studs. The coils are made for the purpose of allowing the wires or strips to twist or untwist without breaking as the pulleys or drums revolve, so that the wire may spring to the form of the pulleys or drums. By this arrangement the wire or strip can adapt itself when passing from the curve or form of the pulleys or drums to the straight again, and so relieve the strain. Such improved means of transmission is specially applicable for driving velocipedes or like machinery. In the figure, which represents one pattern of the new device, A is a pulley or drum, say, for driving a cycle, and B represents a simple shape of recess; C shows the spring coils formed at suitable intervals in the wire D. The ends of the wires can be coupled by, e.g., two solid pieces partaking of the shape of the coils, which are screwed on to the ends and connected together by a pin; but the device lends itself readily to many modifications, as will be understood.

LITHANODE: AN IMPROVED NEGATIVE ELEMENT FOR BATTERIES.

THOSE of our readers who have read the numerous notes on improvements in voltaic batteries which we have published from time to time will be aware that Mr. Desmond G. Fitzgerald has been making an elaborate search for more useful battery elements than those which are well known, and a reference to No. 1107, p. 316, will disclose the fact that some time ago Mr. Fitzgerald took out a patent for a method of utilising oxide of lead which has since been carried to something near perfection. The object the inventor had in view was to produce a dense and coherent mass mainly composed of oxide of lead, which could be reduced to porous metallic lead or converted into conductive peroxide of lead; and, further, to produce by chemical action a superficial coating of peroxide upon the surface of the dense masses, so that the latter could be used at once without preparation by way of charging. This method had been found so successful in the experimental stages that, some months after Mr. Fitzgerald had applied for a patent, a similar specification found its way to the Patent Office; but with that we have nothing to do. At the late meeting of the British Association, Mr. Fitzgerald read a paper in which he drew attention to the merits of Lithanode, a substance which he says is admirably adapted for the negative element of batteries, whether primary or secondary, and is also a perfect anode for the electrolytic separation of the most electro-negative elements—for instance, chlorine. The essential requirements in a negative element for use in a voltaic battery are inoxidisability in itself, and a capacity for retaining its electro-negative condition when constituting a cathode traversed by a strong current for a long time. If economy enters into the question, it is necessary that the cost of the energy developed by means of the voltaic combination should not exceed, say, a halfpenny per horse-power hour, while it is desirable that its cost should be reduced as much as possible, or to, say, one farthing per horse-power hour, which is believed to be within the bounds of practicability. An efficient negative element must also possess a high degree of conductivity, and as an anode it must be chemically unattacked by oxygen or chlorine in the nascent state, must not be disintegrated by the action of gases evolved from its surface, and, while possessing sufficient hardness to resist abrasion, must be capable of production in surfaces of any required area without increasing electrical resistance. A substance which fulfils these conditions was described in the last volume, p. 316, and is known as lithanode, though so far it has not been publicly introduced, except at the meeting of the British Association, where a few experiments were made with it. Planté, about a quarter of a century ago, obtained a peroxide of lead almost identical with lithanode, but it was in the form of very thin layers in contact with metallic lead, which, as will be surmised, involved much local action between the layer of peroxide and the metal beneath it. The thinness of the layers was another disadvantage in the Planté type of secondary battery, but that difficulty was overcome by Faure, whose device was heralded by such a flourish of trumpets a few years ago. Improvements have followed rapidly, as they generally do when the means of making experiments are freely supplied; but there is still a defect, for the local action, which has been considerably reduced, is a cause of continuous waste of energy and of the ultimate destruction of the plate supporting the peroxide. When this view of the facts became understood, it was seen that if an element could be produced of some coherent active material independent of any surface support, the problem would be solved theoretically, and we understand that after many failures a composition was at last formed which enabled the inventor to say that the problem was also practically solved. The question was how to obtain a dense coherent plate of peroxide of lead without the use of any cementing or agglutinating substance of which the effect would be to augment fatally the resistance of the electrode. If we mix oxide of lead with water, and mould the plastic mass thus obtained into the form of a plate, this, as might be expected, will be very friable when dry, and, when immersed in a fluid, will resolve itself into the original pasty form. In order to obtain a coherent solid without the use of an inert cementing body, it is necessary (says Mr. Fitzgerald) to produce a molecular change in the plastic mixture, so as to cause it to "set." Such a molecular change may most readily be brought about by a partial chemical change occurring in the moulded mass, provided such change be not too rapidly effected. If, for instance, we blend a certain proportion of finely-divided metallic lead with the oxide of lead and water, the rearrangement of molecules due to the gradual oxidation of the lead in presence of air will have the effect of greatly increasing the cohesion of the mass so as to allow of the immersion in a fluid without disintegration. The resulting plate, when electrolytically peroxidised, will possess a considerable degree of cohesion and hardness constituting the product known to some electricians under the somewhat barbarous term of petranode. If we mix our oxide of lead with a solution of a salt which will gradually be decomposed by the oxide—as, for instance, ammonic sulphate, from which ammonia is evolved whilst a certain proportion of the lead oxide is converted into plumbic sulphate—we may obtain a dense and coherent mass which, when electrolytically converted into peroxide of lead, constitutes lithanode.

The exact process adopted in preparing the plates has not, we believe, been made known, for experiments on a large scale are still being made, but an idea can be gained from the specification of the patent. Litharge is mixed with a solution of ammonic chloride, sulphate, carbonate, chromate, or phosphate; sodic or potassic chloride, sulphate, or chromate; or an alkaline hypochlorite or silicate, with a proportion of finely-divided metallic lead. The mixture prepared with one or other of these cementing bodies is compressed into plates, and there we have the lithanodes, when they are electrolytically converted into peroxide of lead. The improved plates are entirely composed of the peroxide, and are, consequently, free from local action, while they are not liable to deterioration, and are possessed of sufficient conductivity. When used in batteries, either primary or secondary, they offer a permanent element instead of one which contains the agents of its own destruction; they economise energy elsewhere expended in local action, and they enable the weight to be reduced. In the other patent above referred to the litharge and one of the salts are mixed in the dry state and steamed in moulds. The experiments made with plates of lithanode have been kept secret—probably because the owners of the patent wish to make all possible improvements themselves; but there is not much doubt that the invention represents an important advance, which will be made apparent when opportunity offers, as it may shortly, when capitalists make up their minds to support some of the schemes for working tramcars by storage batteries.

THE AMATEUR WORKSHOP.—XXVIII.

Self-acting Lathes.—(*Continued.*)

A FEW more words on screw-cutting in continuation of our last, p. 147, and we will pass on to other matters. And first as to the position of the saddle itself, which, being slid back after each cut, has to be brought into gear again with the screw at some definite position. When cutting screws in the lathe the position of the saddle at the commencement of a cut will depend upon the relative rates of the leading screw, and of the thread which is being cut. When the number of threads per inch which are being cut can be divided by the number per inch of the guide screw without a remainder, the saddle can be run back, and the clasp nut will fall into gear anywhere without exact setting. Thus with a screw of 12 threads, and leading screw of 4 threads,

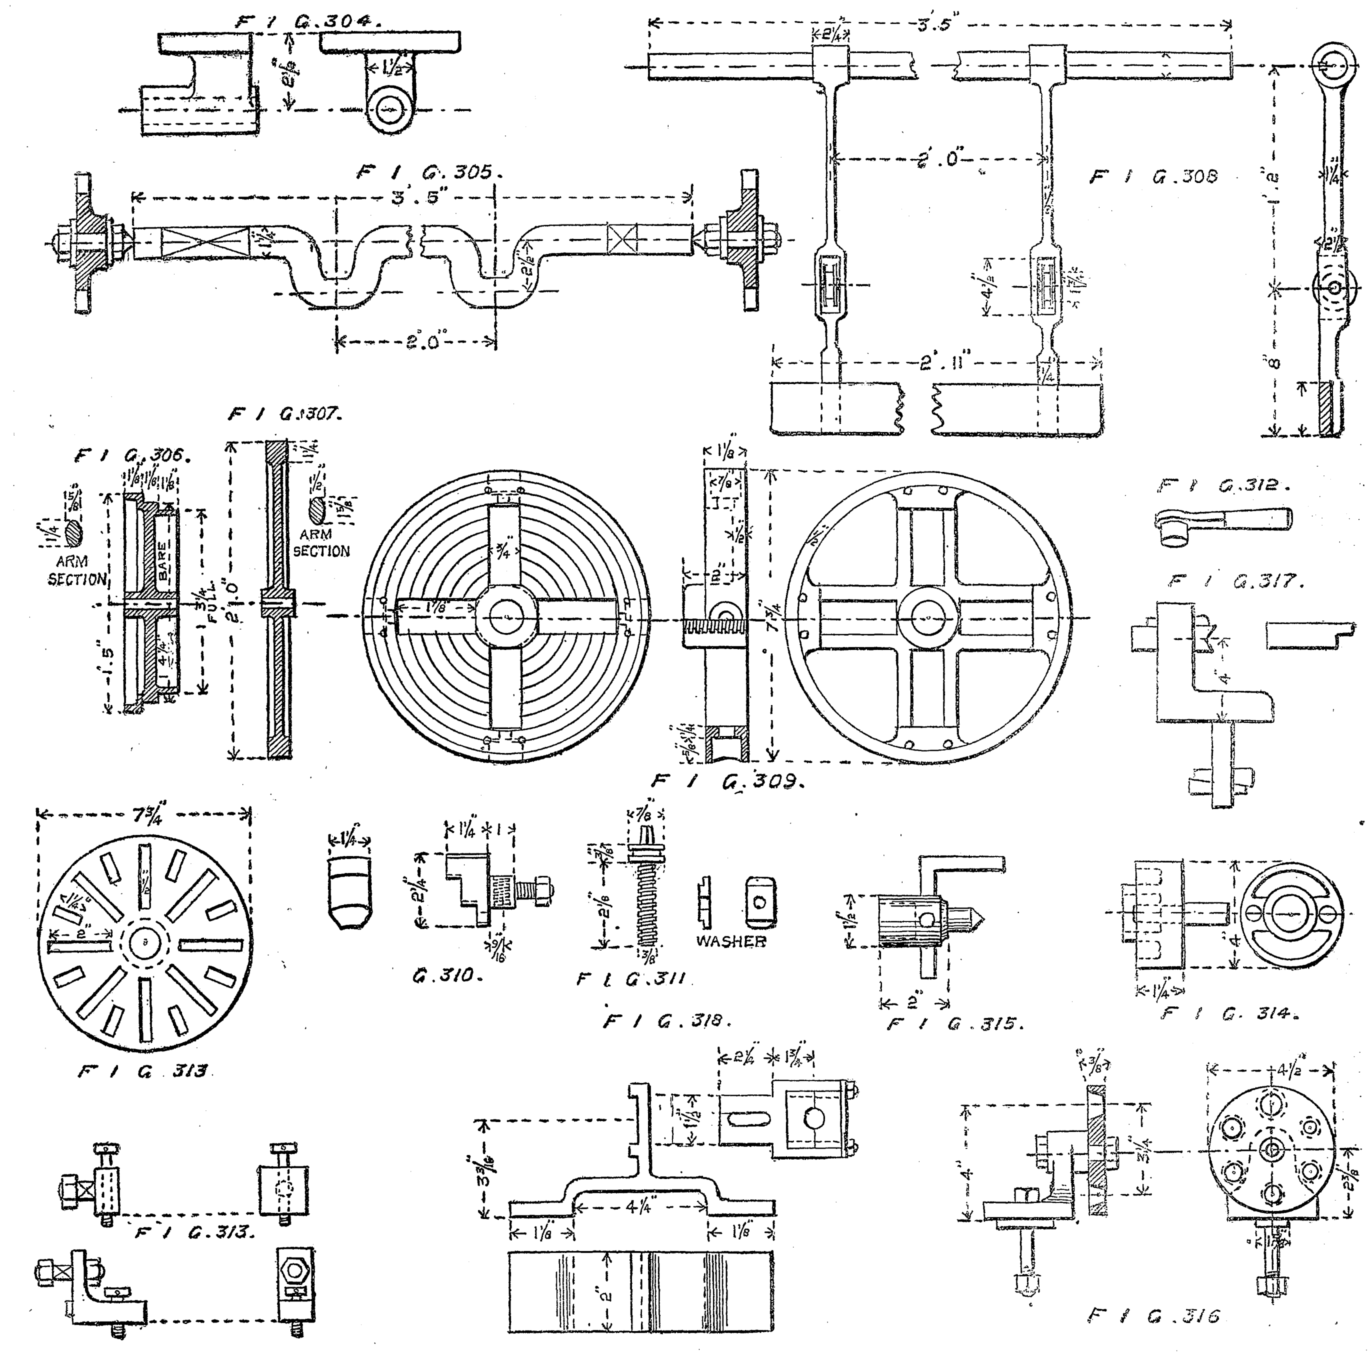


FIG. 304. FIG. 305. FIG. 306. FIG. 307. FIG. 308. FIG. 309. FIG. 310. FIG. 311. FIG. 312. FIG. 313. FIG. 314. FIG. 315. FIG. 316. FIG. 317. FIG. 318.

$\frac{12}{4} = 3$, there being no remainder, no precise setting of the saddle is required. But with an odd pitch which will not divide, we must put down the pitch in fractional form, and the numerator of the fraction will indicate the least number of inches which the saddle will travel to fall into gear again. Thus with a ⅜in. pitch 3 will be the least number of inches, there being 8 complete threads in 3 inches. Or $4\frac{1}{4}$ threads per inch $4\frac{1}{4} \times 4 = \frac{4}{17}$ and 4 is the least number of inches that the saddle will travel, and there will be 17 complete threads in 4 inches. Or multiples of these numbers will be used, as 3, 6, 9, 12, in the first instance, or 4, 8, 12, 16, &c., in the second, according to the length of screw to be cut, and a mark can be made on the lathe-bed as a guide for correct setting of the saddle. When cutting double or treble threads, one wheel of the train, that on the mandrel, must be so chosen that its teeth will divide into two or three equal parts as required, and these marks will be the guides for setting the work in relation to the tool for the second or third thread, as the case may be. Thus having a wheel of 30 teeth on the mandrel, and having, as we will suppose, cut one thread of a triple-threaded screw; stop the lathe, mark with chalk the tooth of the mandrel-wheel which is engaged with the tooth space of the stud-wheel, count round ten teeth on the mandrel-wheel, and mark again, and ten more and mark again. Throw out the clasp-nut, disengage the wheels by lowering the rocking-plate, and turn the mandrel and its wheel around until the second of the chalk marks comes opposite the chalk mark upon the stud wheel into which it gears, and there start the second thread. Afterwards repeat the process to obtain the starting point of the third thread, and the three threads will be of equal pitch and at equal distances behind each other.

Having given enough space to the elementary principles of screw-cutting, I will note how the saddle can be modified for a lathe having rack traverse only. The entire apron shown in Fig. 290, p. 103, is done away with, and in its place there is substituted the casting shown in Fig. 304. This consists simply of a bearing bolted to the underside of the saddle in place of the apron, and carrying the pinion spindle, whose dimensions remain unaltered. The lathe is simplified thereby, though much less efficient.

The driving apparatus is shown in detail in Figs. 305 to 308. The crank is of wrought iron faced with ends of hardened steel, running on hardened steel points. It is turned between centres similarly to the engine crank shown in Vol. XLII., p. 115. Upon it are keyed the driving and flywheels (Figs. 306, 307). The pattern of each wheel is built up in courses of segments in the usual fashion as already described. In the driving-wheel the segments should be thin, say, not more than ⅜in. or ½in. when finished, since thick segments in so slight a pattern would soon become disjointed. The flywheel should have three or four courses. The arms, oval in section in each case, are locked together as shown in Vol. XLI., p. 95, and those belonging to the flywheel are let into the rim segments between the rows during the process of building up. The driving-wheel arms can be let in similarly, but the rim is so slight—⅜in. thick—that I should prefer to make a good butt joint within the rim, and well glue and screw from the outside.

The castings are turned and bored upon the face chuck. When keyed upon their crank axle, the latter should be run round between the centres of a lathe in order to test their truth. If they wabble in a slight degree, as they are likely to do if they have not been turned and bored with great care, a very light cut can then be taken over them, and the file and emery cloth used to polish the belt faces. The diameters of the speeds on the driving pulley are given to suit the centres on Fig. 263, p. 546, of the last volume, or 1in., 2¾in. from the base of the standards. I have shown no balance weight on the flywheel; if desired, it can be cast as a thin plate between adjacent arms, and the wheel keyed on so that the weight shall come on the opposite side to the cranks.

I have shown flat link driving chains and wheels (Fig. 263, p. 546 of the last volume) as being lighter running than the ordinary connecting-rod. This necessitates a special construction of the treadle bearers (Fig. 308), being, therefore, light castings having a recess cored out to receive the wheel, the latter being simply a turned double-flanged roller revolving freely upon a central pin. The bearers are keyed on the treadle bar in the usual way, the bar is

pivoted on dead centres, like the crank axle, the treadle board is a plain piece of wood screwed to its bearers, and, if desired, faced with a strip of broad hoop iron where the foot rests.

The number of chucks which are employed with self-acting lathes is almost legion, being selected according to the convenience, taste, class of work pursued, or purse of the workman. Modern turners are not content without the possession of one or two at least of the many self-centring chucks of American manufacture in addition to the ordinary chucks in common use. Of the common chucks there are the point centre, the fork, the bell, the face, the three or four-jawed, besides drivers and steadies. Two or three of these I will briefly describe, showing how they may be made.

The details of a four-jawed chuck suitable for a 4in. lathe are given in figures 309 to 312. There is first the actual plate (Fig. 309). This consists of a disc $7\frac{3}{4}$in. in diameter by $\frac{1}{2}$in. thick, strengthened with a rib around the edge, provided with a boss screwed to fit the mandrel nose, pierced with four slots to take the jaws, and bossed up at the outer ends of the slots to receive the shoulders of the screws, and the holes for the box key used for setting the jaws. These slot holes should be cored, the core prints being put on the front side of the plate, and to facilitate the moulding, a good taper should be put on the inside of the stiffening ring, and also on the central boss. When the plate is cast, its boss should be screwed in the lathe, the plate then run on its own proper mandrel nose, and its face and edges and back face turned as true as possible. Then run a line round on the circumference to represent the centres of the jaw screws, and drill their holes as most convenient, enlarging those holes afterwards for the box key and shouldered collar, with a pin-drill. File the edges of the slots to templet for the sliding jaws.

The jaws (Fig. 310) in so small a plate would best be made of steel, notwithstanding that case-hardened jaws of wrought iron are used for plates of larger size. The sliding piece, or joggle, behind the actual jaw is properly welded on to the jaw to save the labour of shaping out of the solid. The joggles must be fitted to the slots, and the steps of the jaws turned with light cuts and circular ribbings or grooves turned on their outer and inner biting faces after the washers and nuts have been provided, and the jaws screwed up tightly. The screws are shown in Fig. 311, and the mode of their confinement in the plate is obvious from the figures, where it is seen that pins driven tightly into drilled holes through the plate fall into the turned groove in the shoulder of the bolt, just beneath the square head. Thus the bolt, though free to turn, cannot move endways. The thread may be cut either right or left-handed. The wrench is shown in Fig. 312.

A slotted face-plate suitable for the same lathe, with two clamps of different power, is shown also (Fig. 313).

Two driver chucks are shown in Figs. 314 315, the first being a face or catch-plate holding a pin, and used for work of large diameter, the second, a combined point centre and driver. The latter form is very convenient, because of the radial adjustment which is provided for in the slot hole and pinching screw, and is especially suitable for small lathes, the size of whose screwed mandrel is such that the boring of a hole for the dead centre takes away most of the metal in the nose. The chuck screws over the nose, similarly to the face chucks.

Cone plates and steadies are among the most indispensable adjuncts of a lathe. A cone plate is shown in Fig. 316, and backstays in the figures following. The first (Fig. 317) is simply a bracket or foot wedged to the lathe-bed, and carrying an arm notched out to steady a piece of wood while being turned, two arms being shown in the figure. The second (Fig. 318) is bolted to the back of the saddle of the slide-rest, and carries an adjustable arm A, with loosely-fitting blocks of wood, and since it follows, the work is termed a following steady.

With this I conclude the present subject, and in the next two articles propose to consider such forms of circular and band saws as are most suitable for amateur use.

MOULDING PULLEYS.*

THE drawing, Fig. 1, shows the moulding of a pulley 9in. diameter, 18in. face, rim $2\frac{1}{4}$in. thick, from a ring pattern with loose arm and lifting plate. This pulley was moulded in a foundry that had lately suffered from a fire in which a number of flasks had burned up and there was no flask on hand to make it in. It was an awkward job well done. The ring pattern was levelled up in the floor, rammed and drawn up, the arms bedded in, and the lifting plate shown by the dotted lines and dots A A, fitted in. A large flat, dry, sand core, shown in section at B, and in plan, Fig. 2, was struck up and the core print to be used on top of the hub was bedded in the core, as shown by the large hole in the centre. The two holes to the right of the core print were for the pouring gates, and the one at the left for the riser. This large core was well strengthened by good heavy rods, and made so that extra weight could be placed over the hub to help resist the strain at that point. A parting was made on a level with the top of the hub and the core put on over the top print and weighted down with pigs laid crosswise on it. The rest of the pulley was rammed up on a level with the floor. Broad planks were then laid on the floor lengthwise from the pulley with one edge near the outside of the rim. Other planks were laid across these for standing room when drawing the pulley and to keep from crushing in the edge. Before lifting out the core from over the arms air-slaked lime was shaken down on the inside of the mould and the joint marked with a "lifter" at the parting of the arms to serve as a guide in putting the core back on again. Before setting, the core back ropes were attached to the chains that supported it in the crane to steady it and to pull one way or the other, to guide it into its place. The long broad core plates C C were then placed across the mould a few inches apart all the way round. The runner-box D was built up with a dry sand core E, at the bottom of the basin, and the whole thing weighted down. F F are clamps to strengthen the runner-box, G is the vent from the centre core. The rim of this pulley was poured open and "the word" was given when the rim was full to stop pouring, so as not to run it over. H is an overflow basin. In moulding the pulley the rim was made 9in. deep below the centre of the arms, and 10in. above the centre. This left an inch ring to be cut off the top for whatever dirt might gather.

Casting pulleys in green sand with the rim open is practised in a very few shops, and will be a new feature to many. Although whether made with a lifting plate or with cores for the arms, the outside of the rim is usually made so that it can be checked off, and the inside of the pulley dressed up around the cores or joint. One well known firm that make a great many large pulleys, cast all of them with the rim open. Instead of having a ring 6in. or 8in. wide and drawing it up, which is usually the case, they have two band patterns of each diameter (heavy and light) 36in. deep, and two sets of arms (heavy and light) to suit. Figs. 3 and 4 are a section and plan view of the patterns. In the rim are rows of $\frac{1}{2}$in. holes, 1in. apart on a line from centre to centre, commencing 2in. from the bottom and running diagonally across the face of the rim as far as the centre, as seen in Fig 4. The arms are of cast-iron and have a hole in the end for set screws to hold them to their place until the lower half of the core is rammed up. Pulleys can be made on this plan in much shorter time than drawing up. For instance, to make a pulley 6ft. diameter 12in. face, set the ring on the floor, fasten the arms in with set screws 6in. from the bottom, ram up under the arms, and make the parting for the plate. The set screws can then be taken out and the outside rammed up. The upper half of the rim is left a little deeper to dress up clean in the machine shop; and wrought-iron straps are riveted in flush with the rim to draw it by.

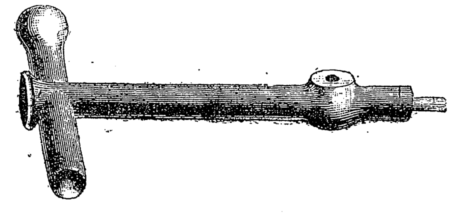
THE DREAMS OF THE BLIND.

A PAPER read before the biological section of the American Association for the Advancement of Science was on "The Dreams of the Blind," by Dr. Joseph Jastrow. The object of the paper was to determine the extreme age at which a child may become blind and yet lose all memory of the visible world, so that it no longer sees in its dreams. Almost all dreams of normal persons are sight-dreams, and a dream is often spoken of as a vision. The blind are deprived of this most important sense; but if they have not been born blind they may remember enough of what they have seen to enable them to imagine how things look and when the imagination has free play in sleep to picture themselves as in full possession of all their senses. Physiologists would explain this by saying that during the years in which they saw, a certain part of the brain has become educated to receive and interpret all these messages which the eye sends, and that when this part of the brain acts spontaneously in sleep the person dreams of seeing.

Such a portion of the brain would be called the sight centre. If now we find out the latest age at which blindness may set in and yet the person keep on dreaming of seeing, we will find out the time it takes for this sight centre to develop. For this purpose about 200 blind persons of both sexes were questioned at the institutions for the blind in Philadelphia and Baltimore, and it was found that those who became blind before their fifth year never dreamed of seeing; of those whose sight was lost between the fifth and the seventh year some did and some did not see in their dreams; while all whose eyesight was destroyed after the seventh year had quite as vivid dream-visions as seeing people. The fifth to the seventh year is thus shown to be the critical period. This period corresponds with the age which authorities assign as the limit at which a child becoming deaf will also become dumb; and also with the age of one's earliest continuous memory of oneself. It is interesting to note that blind persons dream quite as frequent as normal people, and that with those who do not see in their dreams, hearing plays the principal part. When dreaming of home, for instance, they will hear their father's voice or their sister singing, and perhaps will feel the familiar objects in the room, and thus know they are at home. We, in such a case, would see it all.

RIVETING TOOL.

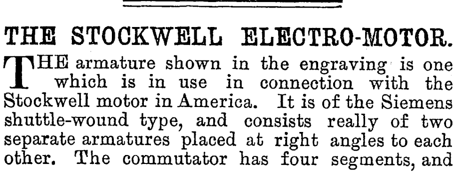
THE construction of this tool is very clearly shown in the figure herewith presented. On one end of the shank or body portion is a punch about the size of an ordinary copper rivet, and on the other end is a suitable boss to receive the blows of a hammer. One end of the head piece has a concavity shaped to give a proper form to the upset end of the rivet, and at the other end is a boss for striking upon. To use the tool, the parts to be united by rivets are first pierced by the punch,



when the rivet is inserted and the usual washer put on. The projecting end of the rivet is then placed in the hole in the shank of the tool, when the stroke of a hammer forces the washer down tightly to the work. The concavity is then placed over the end of the rivet, which is then upset and given a neat convex finish by blows delivered upon the opposite end of the head piece. The punch may be made removable, and the hole in the shank may be formed in a removable sleeve, to adapt the tool for use in setting rivets of various sizes. This handy riveting tool is the invention of Mr. James H. Stevens, of Grover, Col.—*Scientific American.*

THE STOCKWELL ELECTRO-MOTOR.

THE armature shown in the engraving is one which is in use in connection with the Stockwell motor in America. It is of the Siemens shuttle-wound type, and consists really of two separate armatures placed at right angles to each other. The commutator has four segments, and



the terminals of the wire on each part of the armature are connected to opposite segments. The latter are not made parallel with the spindle, but are helical in shape, so that there is no break in the circuit at that point, since the brush passes the current to one armature before leaving the other. By this arrangement only one armature is in action at one time. Taking the one to the right, for example, it yields its maximum effect during the quarter revolution when the polar faces of the armature are approaching the pole pieces, and until they come directly opposite each other. During the next quarter revolution the armature is cut out of the circuit entirely; in the third quarter it again comes into the circuit until occupying the same relative position as in the first quarter; and, finally, in the fourth quarter it is again cut out. But during each of these idle periods of the armature to the right, that to the left comes into circuit, and goes through relatively the same cycle of operations.—*Electrical Review* (Lond.)

SCIENTIFIC SOCIETIES.

ROYAL MICROSCOPICAL SOCIETY.

THE first meeting of the session was held on the 13th ult. at King's College, Strand, W.C., the President, Dr. Dallinger, F.R.S., in the chair.

Letters were read from Prof. H. de Lacaze-Duthiers and Prof. W. A. Rogers, in acknowledgement of their election as Honorary Fellows of the Society.

The President said that it fell to him to take notice of the fact that Mr. George Busk, F.R.S., an Honorary Fellow of the Society, had died since the date of their last meeting. He had been intimately associated with their Society, having been its President in 1848 and 1849, and although he (Dr. Dallinger) never had the pleasure of a personal acquaintanceship with him, the name of Mr. Busk had been before him from the time of his very earliest studies. Everyone was familiar with his labours in connection with the Polyzoa, and he felt sure that all present would regret to receive the intimation of his decease. An excellent portrait in oils of Mr. Busk, painted by his daughter, had recently been presented to the Linnean Society, while an appreciative memoir had been published in *Nature* by his friend, Prof. Allman.

Mr. Curties exhibited several of the new apochromatic objectives (with a series of eyepieces) made of the new kinds of glass from the Jena manufactory, which were examined by the Fellows with great interest, the very high eyepiece which they carried without "breaking down," being a special subject of comment.

Prof. Abbe's paper, "On Improvements of the Microscope with the Aid of New Kinds of Optical Glass," was read.

The President said he had been greatly interested by the explanation given in Prof. Abbe's paper, and the Fellows would doubtless be glad to know that the 1-12in. objective was in the room that evening, and fitted to a microscope with a suitable eyepiece, so that its perfection could be seen by those present.

Mr. Cheshire inquired whether the new kinds of glass could be bought in this country, and if full particulars could be obtained as to their refractive indices, dispersive powers, &c., so as to make it possible for similar objectives to be made here in due course by English opticians? The objectives shown that evening gave results which he could only describe as most magnificent.

Mr. Crisp said that a very full and complete descriptive catalogue had been published in which all particulars were given as to the optical qualities of the glass. Indications were given as to the best kinds to be used in the construction of objectives for telescopes, &c.; but with regard to microscope objectives, the subject was dismissed with the remark that "it must be left to the skill of the practical optician to choose the most suitable from the above series. The new objectives show what can be attained in practice." It was, of course, quite fair to keep such a matter as a trade secret.

Mr. T. B. Rosseter's paper on "*Trichodina* as an Endoparasite" was read by Prof. Bell. The author described a very careful series of observations by which he had established that this infusorian, hitherto only known as an ectoparasite, infested the urino-seminiferous organs of newts. Apparently the animals were of a different species to that (*T. pediculus*) parasitic on the tentacles of *Hydra*, as, when placed in a watch glass together, the *Trichodina* took no notice of the *Hydra*, and if they struck against it they recoiled as it were from the contact and continued their course.

Dr. Crookshank said it would, perhaps, be remembered that during the last session he read before the Society a paper on "Photomicrography," in illustration of which he then showed a number of photographs of Bacteria. He had done some further work in that direction, and had brought with him a new negative which he was anxious the Fellows should examine, because it was one in which the flagella of a *Vibrio* were very distinctly shown. It would, no doubt, be known to most of the Fellows that some persons had doubted the existence of a flagellum; but, although it was a thing very difficult to be seen, this was not the first time that it had been photographed. Koch had been able to do this after a process of staining, for which he recommended the use of a watery solution of logwood and subsequent treatment with chromic acid; but he had rather given up the attempt to photograph specimens unless he could get them stained brown. This, however, he (Dr. Crookshank) had not found to be essential when using isochromatic plates; the specimen shown had been stained with gentian violet, and it would be found on examination that the flagella were very distinctly seen. He would also hand round for inspection another negative to show that it was possible to get very good results without staining brown; the specimen being *Spirochæta* from sewage contaminated water, for which he was indebted to Mr. Cheshire. He had also mentioned in the paper to which he referred that in reproducing the photographs the colour given to the prints was rather objectionable, and he had suggested to the Autotype company that they shouldtry to use some other colouring matter for the purpose. It had been found very difficult to carry out this idea at present; but what he desired to do was to be able to print in such a way as to reproduce the objects of the same colour as the stain with which they were originally prepared instead of in the ordinary photographic tint. The micro-organism exhibited had been enlarged 2,500 times.

The president said that to him it was of exceeding interest to examine the photographs which had been brought for their inspection by Dr. Crookshank, seeing that they depicted objects which for years he had been drawing and studying. Koch had for a long time failed to detect the flagella with his eye, but when he photographed the object the flagella appeared. Now that they were able to obtain photographs in the manner which Dr. Crookshank had so successfully adopted, they would be able to see for themselves all the minute details which had been described. He felt it was a great gain to have photo-micrography so readily and easily at disposal, and personally he felt very much obliged to Dr. Crookshank for bringing the matter before them.

Mr. Crisp inquired if Dr. Crookshank had tried to obtain photographs by means of the new objectives. One of the greatest advantages claimed for them was their use in photo-micrography, apart from the advantage of being able to obtain the same power with an $\frac{1}{8}$in. objective as he had obtained with the very much higher powers used in producing the negatives exhibited.

Dr. Crookshank said he had not yet had any opportunity of trying either the objectives or the projection eyepieces. His negatives were taken with a $\frac{1}{25}$in. by Powell and Lealand.

Mr. C. D. Sherborn and Mr. F. Chapman's paper "On some Microzoa from the London Clay Exposed in the Drainage Works, Piccadilly, in 1885," was taken as read, as it had been printed during the recess.

Dr. Anthony's paper on "The Observation of Opaque and Quasi-Opaque Objects in the Microscope" was taken as read, having been printed during the recess.

Prof. F. Jeffrey Bell said that the subject of grouse disease was always more or less attractive to those who were interested in these birds, but yet nobody seemed to know with any certainty what it really was. A short time ago two grouse which had been found dead on one of the moors were sent up to him, and he had made an examination of them with the idea of ascertaining if there were any appearances in their organs which would throw light upon the subject. There were, of course, any number of theories to account for the disease, and it had been often said that it was due to the presence of animal parasites in the liver. Another opinion was that it was caused by a worm (*Strongylus*) which was found by Dr. Cobbold, and was considered by him to have been the undoubted source; it was also said to be caused by a species of tapeworm (*Tænia*). He had, therefore, carefully examined the two grouse in question, but found all their organs healthy, with no sign of any disease likely to account for their death. Nothing of the nature of *Coccidia* could be discovered in the liver, and though he carefully examined the large cæca he failed altogether to find Dr. Cobbold's parasite, but he found that about 6in. of the intestine was occupied by a *Tænia calva.* This appeared at first to be of some importance, because when the large size of this tapeworm was considered, it was easy to suppose that a considerable stoppage might be caused by it. One of the grouse had two tapeworms and the other had three—the former of these had its fæces quite healthy, the latter had them more watery—but, so far as appearances were concerned, he came to the opinion that if the grouse were otherwise healthy and well-nourished, probably the tapeworms were not doing very much harm; for, whilst the grouse with the two tapeworms was in rather an emaciated condition, the one with three was in good condition and apparently perfectly healthy. He, therefore, came to the conclusion that the tapeworms were neither the immediate nor the remote cause of the death of the two grouse, and that they neither died from Dr. Cobbold's declared cause, nor from the presence of *Coccidia* in the liver. He was inclined to the opinion—which he believed was held by many sportsmen and gamekeepers—that the disease was due to some condition of the heather or whatever else the birds fed upon, rather than to the attacks of animal parasites.

Mr. J. Joly's "Note on a Needle for Manipulating Objects in Canada Balsam," was read by Mr. Crisp.

Prof. F. Jeffrey Bell said that during the present year he had been interested in a worm, the origin of which was undoubtedly exotic, and which had

not been found in this country except in hot-houses. It appeared to have been first noticed here in 1878, in the Palm-house at Kew, from which circumstance it had received the name of *Bipalium Kewense*. Subsequently it was found at Welbeck, and since then at the Zoological Gardens and other places which were in direct relation with Kew. More recently he had received it from various correspondents, some of whom were not in relation with Kew; but all were agreed that it had come to them in connection with orchids, and there seemed to be a general opinion that it had come from Burmah. Prof. Moseley, however, thought that it had come from Japan. A remarkable circumstance in connection with it was that no specimen had yet been found with generative organs, although it was quite certain that it multiplied and grew with rapidity. It was, therefore, a matter of wonder how such increase could, under these conditions, be accounted for, and the suggestion was made that it might possibly be by transverse fission, a process which had been the subject of some controversy. Sir J. G. Dalzell and others asserted that Planarians divided transversely, whilst, on the other hand, Schultze stated that he had seen large numbers, and kept them under observation, but had never seen any indication of transverse fission. It was further stated that this mode of reproduction only occurred in the case of those with straight intestines; but, again, in 1883 another observer, Von Kennel, reported that he had himself seen transverse fission take place in a Planarian with branched intestine. Whilst he (Prof. Bell) could not show conclusively from actual observation of the process, that *Bipalium* did divide in this manner; yet he thought he had obtained evidence sufficient to warrant the belief that such was the case. He received, some time ago, two specimens from Gosport (drawings of which he had made upon the blackboard). One of them had the hammer-head shape at one end; but the other, which was a very small specimen, had no trace of it, but was simply pointed at both ends. Unfortunately, one of the Gosport specimens got lost; but he watched the small one carefully day by day, and on the 5th of October—or 11 days after it had arrived—he noticed a delicate fringe running round the anterior end. This fringe had since grown and grown until at the present time it was very obviously a hammer-head, so that it was clear that a creature of this kind might, in the course of three weeks, attain the perfect condition. A specimen from Liverpool, which had been divided into two in the post, was afterwards found to be in three pieces. At first he thought the third might have been previously overlooked amongst the moss; but on measuring the portions he found one to be 27mm. and the other 16mm., so that it seemed tolerably certain that at some period between the 29th of September and the 5th of October, the piece which had originally measured 41mm. had divided into two. He thought it might be conceded that the observations proved: first, that spontaneously a *Bipalium* would divide into two; and, secondly, that given repose, a piece of a *Bipalium*, pointed at both ends, would thicken, and form the hammer-head extremity, which was a characteristic of the adult.

Prof. Stewart, in reply to the President, said he had no remarks to make with reference to this very interesting communication; but he might perhaps mention that, having had the opportunity of seeing the specimen which had reproduced its head, he had no hesitation in saying that it was a bonâ-fide head. He could, therefore, entirely confirm the observation, although he need hardly say that confirmation was quite unnecessary in the case of so able and careful an observer as Prof. Bell.

SOCIETY OF ENGINEERS.

At a meeting of the Society of Engineers, held on Monday evening, a paper was read on "Liquid Fuels," by Mr. Percy Tarbutt, A.M.I.C.E., and Fellow of the Chemical Society.

The author commenced by saying that, though the use of liquid hydrocarbons as heat-producers was by no means of recent date, yet special circumstances at the present time had brought it more prominently to the front. Liquid fuels were not confined to petroleum, but included also tar and residual oils from tar distillation, shale oil, by-products from blast furnaces, &c. Of these, petroleum, though long known, had only of late years been largely drawn from its almost limitless resources, chiefly in Northern Pennsylvania and on the shores of the Caspian Sea. Many other countries all over the world produce it in lesser but yearly increasing quantities. New discoveries were constantly being made, and the distribution of petroleum seemed to be as universal as that of coal. Gasworks were large producers of liquid fuel in the shape of tar and its products. With the increase in the supply of petroleum the modes of its conveyance had also advanced. Barrels had been superseded by tanks adapted for use on railways, roads, canals, and sea-going vessels. Pipe-lines for oil conveyance had wonderfully developed, there being 9,000 miles of them in the United States and great lengths in the Caspian districts, where 600 miles of pipe line was about to be laid down from the Caspian to the Black Sea, an undertaking that would revolutionise the oil markets of Europe. In making a comparison between the heat-producing values of coal and oil only a general average could be taken, the qualities of each varying so largely. Estimating thus from chemical analysis, the theoretical value of coal was 14·5lb. of water evaporated per pound of fuel, and of oil 20·7lb., the higher value of oil being due to the larger proportion of free hydrogen it contained. Practically, various circumstances, detailed by the author, increased the difference of value. He then described the ordinary modes of burning oil, in nearly all of which it was effected by the use of steam "pulverisers" or spray producers. Some attempt had been made to burn oil without steam spray-producers, as in Nordenfelt's trough arrangement, but these were not generally suitable for firing steam boilers. The essential condition was that the burning gases from the oil should be kept from contact with the boiler-plates, which were necessarily of so low a temperature as to prevent perfect combustion. The author then described his own furnace, based on heating by radiation only, and the starting apparatus used with it. It was found that there were great objections to the use of steam for the injectors for marine boilers. He had, therefore, devised a system of injection by compressed and heated air, which entirely overcame this difficulty, by which perfect combustion was obtained more easily than by using steam. The author concluded by giving comparative results communicated to him by some of the firms who had his system in constant use. These results showed that the work performed was from twice to three times that of coal, besides which there was considerable saving in labour, greater cleanliness, no smoke, and an increase in the steaming capacity of the boiler to which it was applied.

Alaska.—The *New York Times* publishes detailed reports of the proceedings of the expedition for the exploration of Alaska, which is commanded by Lieutenant Schwatka, of the United States Navy. On their way to Mount St. Elias, the expedition crossed a river the existence of which was previously unknown! Eight miles from its mouth its width was a mile, and it flowed at the rate of ten miles an hour. The glacier detritus which it brings down from the mountains colours the sea for miles; it is probably one of the greatest rivers which empty into the Pacific Ocean. It has been named the Jones River, after Mr. George Jones, of New York, one of the promoters of the expedition. Towards the east, the explorers saw a great glacier, fully 20 miles broad, which extended for 80 miles along the foot of the St. Elias range. Assuming that the surface of the ground on which it rests is level, they estimate that this glacier must be 1,000ft. thick. It was named the Agassiz Glacier, and another glacier, extending towards the west, was named after Prof. Guyot. A three days' march brought the party to a third great glacier, which was named after Prof. Tyndall. Starting from this point, they set about penetrating as far as possible into the interior of this magnificent but desert region. For this an unbroken march of 40 hours was indispensable. Leaving the bulk of their provisions and impedimenta behind, and taking only the minimum of what was necessary, they journeyed for 20 hours till they saw the southern face of the great mountain, which is defended by this great ice-zone. They saw before them glacier cliffs rising perpendicularly to heights varying from 300ft. to 3,000ft. They had been travelling over the Tyndall Glacier, which had not hitherto presented any exceptional dangers. But it now began to yawn with crevasses, sometimes 30ft. wide and of unknown depths, spanned by ice bridges as slender as the ridge-tiles of a roof. But the explorers surmounted all difficulties till they reached an elevation of 7,200ft. above the sea. Considering that the greater part of the journey had been well above the snow line, this must be regarded as very creditable. At this point they were surprised by a thick fog, which kept them prisoners in a most cheerless and even dangerous position for four days. On the advice of Mr. Seton Karr, an English gentleman who had joined the expedition, and who declared that any further advance in that direction was impossible, the explorers agreed to descend. Lieutenant Schwatka proposes trying the northern and eastern slopes of Mount St. Elias; he does not despair of yet reaching a greater height, and may in any case obtain valuable additions to our geographical knowledge. Most probably the summit will still remain inaccessible. During the expedition three new peaks were discovered, varying in height from 8,000ft. to 12,000ft. They were named after President Cleveland, Secretary Whitney, and Captain Nicholls.

SCIENTIFIC NEWS.

The scientific session opens with the month of November, and the societies will soon be in full work. The Royal holds its first weekly meeting on the 18th, and on the 30th the anniversary will be held, when the president, Prof. Stokes, will deliver his address, and the council and officers will be elected. The Mathematical Society meets on the 11th, when the retiring president, Mr. J. W. L. Glaisher, will speak of changes in the Mathematical Tripos and its influence on mathematics. Sir Jas. Cockle is proposed as president. The opening meeting of the Geologists' Association will be held to-day at University College, when the president, Mr. W. Topley, of the Geological Survey, will deliver an address on the "Erosion of the Coasts of England and Wales."

Next year will be the year of exhibitions, and amongst the most notable will be that held at Manchester. There will be eight sections, the principal of which will be industrial design, machinery in motion and general engineering, chemical and allied industries, and handicraft work in process of production. The site chosen is at Old Trafford, adjoining the Botanical Gardens, which will probably form part of the exhibition, and is easily reached by road or rail from all parts of Manchester and district. The guarantee fund already exceeds £132,000, and the council and committees include the chief men in their respective departments.

It is intended in May next to open at Saltaire an international exhibition in aid of the building fund of the new Schools of Art and Science, now being built for the Salt Schools, at a cost of over £12,000. The exhibition is to be chiefly of works of art, many of which are already promised on loan, and of industrial processes. It was originally intended to open the exhibition in June last, and advantage has been taken of the postponement to improve and extend the original plan very considerably, so that it is now expected that the exhibition will be on a scale not hitherto attempted in Yorkshire.

A fine art and industrial exhibition will be opened at Elgin towards the end of this year.

Glasgow is to have an exhibition in 1888 in Kelvin Grove Park. It will be international, a motion to make it exclusively Scottish being lost by 55 votes to 7!

The deaths are announced of Dr. Victor Pierre, professor of physics in the university of Vienna; and of Dr. Carl Heinrich Althaus, extraordinary professor of philosophy in the university of Berlin.

The free Saturday evening lectures given at the Finsbury Technical College have, it is stated, been appreciated by the public; but on another occasion it would be advisable to make them more widely known beforehand.

It is stated that carbonate of manganese has been discovered for the first time in this country, at a short distance from Harlech, in North Wales. Some years since an earthy deposit of the black oxide of manganese was found. It was worked for some short time, but being of little value the mine was abandoned. Recently, on exploring below the dark-coloured bed, a light-coloured deposit was discovered, which proved to be a carbonate of manganese. The owners of the Mostyn Ironworks have become the proprietors of this ore, and considerable quantities have been sent to Mostyn, to be used in the manufacture of spiegeleisen.

A patent has been obtained for the manufacture of ink from waste dye liquors. The spent liquor of bichromate of potash or soda which has been used for mordanting wool, &c., is boiled with spent logwood liquor which has been used for dyeing. A small percentage of sulphate of soda is added, and a fast and non-corrosive ink is obtained.

In his introductory remarks at Edinburgh University on the "Sense of Hearing," Prof. Rutherford discussed the theory of sound sensation advanced by Helmholtz, and the theory of the cause of concord between tones of the same pitch. According to Helmholtz, a compound vibration is analysed in the cochlea. If the blending of each sensation in a compound sound eventually takes place in the centre of perception, why, Prof. Rutherford asks, is there

any need to have the complex vibration analysed in the cochlea?

An exhibition of telephony is to be held in Brussels at the beginning of next year, under the auspices of the Société Belge des Ingénieurs et des Industries. The exhibition will be international, and will include all the apparatus and processes hitherto devised for the transmission of the voice to a distance. In addition to apparatus, plans, models, and diagrams will be received. No charge will be made for space during the five weeks the exhibition will remain open. Applications must be sent in before December 1st, to the secretary of the Society above named.

In Detroit, Michigan, the Edison underground system is being put down. The pipes are large-sized gas-pipes, and the wires, twisted in cables, are run through them. Every 20ft. there is a curve in the cables to allow for contraction in cold weather, and at these points are what are called coupling boxes. It is from these boxes that the single wires necessary to supply a building will be run through a small pipe. Connection can be made at any time with any building as easily as gas can be carried into a store or residence. The greater number of pipes and cables leading from the depot are called feeders. They carry the current to large junction boxes, located at convenient points, and from these junction boxes the supply current is carried in four directions, half-way to other junction boxes. Only the incandescent light will be supplied by the Edison Company.

The electric light is an advantage to vessels going through the Suez Canal, the *Salazie*, belonging to the Messages Maritimes, having recently made the passage in 16 hours, passing 22 vessels *en route*.

A recent addition to the French line of Transatlantic steamers running between Havre and New York, *La Bourgogne*, has made the trip from port to port in 7 days 5h. 8m. mean time; her average speed being over 18¼ miles per hour. She resembles the *Etruria*, of the Cunard line, as respects her general dimensions, except that she has less beam by 8ft., and is not quite so long. *La Bourgogne* is 508ft. long, 52ft. 2in. wide, and 38ft. 4in. depth of hold. She has a propeller, 22ft. 8in. in diameter, and has a maximum of 8,100 horse-power. The hull is made of steel. She is rigged with four metal masts, and her sails are hoisted and lowered by steam-power. The entire cost of *La Bourgogne* was £355,000. She registers 9,000 tons.

In consequence of increased demands from public bodies for grants of fish for the purpose of stocking depleted waters, the National Fish Culture Association have considerably widened the scope of their operations by erecting a new hatchery and enlarging the rearing ponds at their establishment at Delaford Park, Bucks. The association have also formed a series of additional ponds for propagating coarse fish as well as salmonidæ. A large consignment of German carp arrived at South Kensington last week, and further consignments are to be imported for distribution, as the German carp is superior to any we have in this country.

M. Laurent has recently described a series of experiments made to ascertain the influence of microbes on vegetable life. Seeds of buckwheat were sown in pots containing four different kinds of mould. In the first natural mould was employed, in the second the same earth sterilised and then inoculated with bacteria of the soil, in the third simply sterilised mould, and in the fourth sterilised mould with the addition of chemical manure. Precautions were taken to prevent contamination of the four receptacles. The production of wheat in each of the pots respectively was in the proportion of 94, 96, 23, 66. In all the experiments the third series was inferior to the others.

A paper was recently read before the Paris Academy of Sciences, on the temperature of the bed of oceanic basins compared with that of the continents at the same depth, by M. Faye. In connection with the reference made to this subject in the opening address of the President of the British Association at Birmingham, the author takes the opportunity of generalising the law already established by him respecting the more rapid and deeper cooling of the earth's crust under the seas than under the continents. Not only is this law applicable to the Polar seas, whose lowest depths have a temperature very near zero C., but also to those which do not freely communicate with the Poles. In these waters also the temperature decreases with the depth, the difference between them and the continents at the same depths being, within about 15°, as great as for the oceans.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents. The editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, *332, Strand, W.C.*

All Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks, a vice from whence great inconveniences derive their original."—*Montaigne's Essays.*

THE WORK OF A REAL MAN OF SCIENCE—TWILIGHT—REDUCING A STAR'S PLACE FROM A CATALOGUE — ARTIFICIAL HORIZON — ASTROLOGY AND THE LAW—STAR DISCS? —"PERFORMANCE GUARANTEED"—RELIEF MAP OF THE MOON—SOLAR SHADOWS ON THE EQUATOR AT THE EQUINOXES.

[26440.]—It is a pretty familiar fact that we are indebted for practically all we know on the subject of scintillation to that eminent Belgian savant, M. Ch. Montigny. Looking through a list of his works since the year 1851 in the *Bibliographie Académique* of the Royal Academy of Belgium, I find the titles of no less than sixty-three memoirs, reports, and essays, in addition to those of four others contributed to other societies, and numerous articles in *Ciel et Terre*. I wonder how many of our F.R.S.'s have done an equal amount of hard and honest work for science.

Would "R. E. F." (reply 60484, p. 177) mind giving us his authority for the statement that "the theory that twilight lasts until the sun is 18° below the horizon is pretty nearly absolete [*sic*] now"? I ask the question because, taking down a few books at random from their shelves, I find this given at the angle of the sun's depression when the last trace of light fades from the sky: for example, in Arago's "Popular Astronomy" (English edition), Vol. II. p. 117; Main's "Rudimentary Astronomy" (first edition), p. 37; Nichol's "Cyclopædia of the Physical Sciences," p. 749; Loomis's "Treatise on Astronomy," p. 57; Brinkley's "Astronomy" (revised by Stubbs and Brünnow), p. 45; Ball's "Elements of Astronomy," p. 154; Chauvenet's "Spherical and Practical Astronomy," Vol. I. p. 218, and so on. I must, however, add in fairness that Schmidt, from the mean result of observations made in 1865, found that astronomical twilight ended when the sun was 15° 55′ below the horizon. This would make the duration of twilight at the Equator one hour and about four minutes, instead of 1h. 12m. But, after all, meteorological conditions enter into the discussion, and considerably complicate the geometrical treatment of the question. This was shown more than 135 years ago by Lacaille, who, while on his voyage to the Cape of Good Hope, says—"On the 16th and 17th of April, 1751, being at sea and becalmed, with an extremely clear and serene sky, in which I could distinguish Venus on the horizon of the sea like a star of the second magnitude, I saw the crepuscular light terminated by an arc of a circle, as regular as possible. Having set my watch to true time at sunset, I saw this arc become confounded with the horizon, and I calculated by the hour at which I made the observation that the sun was depressed on the 16th of April to the extent of 16° 38′, and on the 17th to 17° 13′." Rothman, on the other hand, found that twilight did not absolutely cease until the sun had descended 20° below the horizon, while Riccioli determined the angle at the Equinoxes to be 16° in the morning and 20° at night; 18° then is about the mean of numerous observations. Dr. Mann is himself "quite wrong" in his definition of the cessation of twilight, which ceases at the instant that the crepuscular arc coincides with the horizon, and *not* when sixth-magnitude stars begin to appear in the zenith. Schmidt (*Ast. Nach.* No. 1495) gives the angle of the sun's depression as 11° 39′ when the 6th magnitude stars appear; but, as I have said above, determines that astronomical twilight does not end until the sun is 15° 55′ below the horizon.

In reply to the first part of query 60722 (p. 183), it is customary in practice to add together, each with its proper sign, the precession and proper motion of a star, and to multiply their sum by the number of whole years that have elapsed since the date of a catalogue to obtain the mean place of such star at the beginning of any given year, and then in the subsequent reduction to treat $\triangle c$ and $\triangle c'$ as separate quantities, and multiply them by the fraction of the year which has elapsed between January 1 and the date for which the apparent place is sought. Take, for example, "Veuton Veor's" own star, γ Orionis. The Greenwich Nine-year Catalogue for 1872 gives its mean R.A. for January 1 of that year as 5h. 18m. 15·926s., and its mean N.P.D. 83° 46′ 6·19″. Its annual precession, secular variation in annual precession, and proper motion in R.A. appear as + 3·2158sec., + 0·0048sec., and + 0·002sec. respectively, the corresponding quantities in N.P.D. being − 3·632″, + 0·463″, and + 0·04″. In order, then, to obtain the Mean R.A. and N.P.D. of this star for 1886, Jan. 1, we should proceed thus—

+ 3·2158sec. annual precession in R.A.
+ 0·0048sec. variation of ditto.
+ 0·0020 $\triangle c$ (in *time*).

3·2226
14

45·1164 seconds and 5h. 18m. 15·926s. + 45·116sec. = 5h. 19m. 1·042s., the mean R.A. of the star for 1886, Jan. 1. Similarly—

− 3·632″
+ 0·463
+ 0·440

− 3·129
14

− 43·806

and 83° 46′ 6·190″ − 43·806″ = 83° 45′ 22·384″, its mean N.P.D. Then the remainder of the reduction is familiar to your correspondent, save apparently in the case of $t\triangle c$ and $t\triangle c'$; the t in which is obtained by simply adding ·0029 to the fraction of the year (*vide* p. 489 of the *Nautical Almanac*). This, in the case of November 1st, is ·8323 and ·8323 + ·0029 = ·8352, our required multiplier t. Of course, ·8352 × ·002sec. = ·0016704 sec. or $t\triangle c$, and ·8352 × ·04″ = ·33408″ or $t\triangle c$. I cannot answer the second part of your correspondent's query offhand, and I really have no time to face the calculation necessary to do so; inasmuch as it would involve the computation of the places of several stars whose N.P.D. exceeds 90°, both with Airy's and Bessel's numbers, as well as by the independent quantities, in order to discover if any law governs the alleged discrepancy of which "Veuton Veor" speaks. Of course, though, as the R.A. and Dec. of a star change slowly, if we are dealing with a period very remote from that of the Catalogue, it may be a little better to use the independent constants.

The cheapest artificial horizon that "Jack" (query 60754, p. 183) can employ is simply a bucket of tar, as its slight viscidity renders it less susceptible to a breeze than a surface of water. Gauze, or muslin, would effectually destroy reflection, and no glass cover—save one composed of a sheet whose sides were ground rigidly parallel—would be of the slightest use.

I rarely, if ever, comment on anything which appears in the trade columns of this journal; but I cannot help observing that there is an announcement (dated from Bristol) in the middle column of p. viii. of the cover of the number for Oct. 22, which quite clearly brings the advertiser within the provisions of the Act 5 Geo. IV. c. 83, s. 4.

Unfortunately, my own series of the R.A.S. *Memoirs* only begins with Vol. XXXVI., so that I have no means of reference to the passage quoted by Mr. Sadler in the final paragraph of his letter (26413) on p. 190.

Were I "Enquirer" (query 60761, p. 203), I should refuse to accept any such vague warranty of a telescope as that contained in the words "performance guaranteed," and should insist upon the instrument dividing certain specified stars and exhibiting certain objects upon any average night.

In reply to query 60810 (p. 204) a relief map of the entire moon, or of any considerable part of it, would be a most arduous and difficult piece of work for any one to undertake, presuming, of course, that anything like accuracy was aimed at. Moreover, for obvious reason, it must be made on a globe (or, at any rate, a hemisphere), and so could hardly legitimately be called a "map" at all. To model an individual crater, careful micrometric measurements of it should be made, and a plan executed from them as in the case of a terrestrial survey. The heights of the various parts of the

formation must also be accurately determined in the manner described on pp. 554 et seq. of Neison's "Moon." Then, laying down the plan upon a planed board, wires must be inserted at the proper points, and cut off to the heights thus determined (reduced, of course, to the scale of the plan). The model is completed by filling it up to these various heights with modelling clay, or with the composition described by Mr. Browning as having been employed for that purpose by the late General Worster. It consists of prepared chalk, milk of sulphur, and gum water, which can be worked upon in a plastic state for some time, and sets very much harder than plaster of Paris. It can even be further altered then by moistening it with gum-water again. From this, when dry, any number of casts may be made.

Mr. Hampden is quite right in his supposition (expressed in query 60811, p. 204) that the shadows cast (at sunrise and sunset) by a vertical rod on the Equator at the date of Equinoxes are straight lines—in the sense that any short line is straight upon a sphere of relatively enormous radius—and that they point west and east at those times respectively. Of course, at solar noon, such a rod casts absolutely no shadow at all.

A Fellow of the Royal Astronomical Society.

VEGA AND STARS NEAR — VARIATION OF LATITUDE—THE NEW STAR OF 1572.

[26441.]—I AM much obliged to "F. R. A. S." (letter 26389, p. 171) for looking up the faint stars near Vega. Mr. Tarrant has also kindly observed them for me with his 10in. reflector. He rates A 9·8 and B 10·0 mag. in Σ's scale, and sees 16 out of the 50 other stars shown on the tracing from MM. Henry's photograph (letter 26177, p. 10). He rates δ 10·7, γ 10·8, ε 11·0, and ζ 11·2 mag. in Σ's scale; but he observes that in all cases of the nearer stars allowances must be made for the brightness of Vega. He marks the two brightest stars south of Vega (at about 168° : 240″ and 196° : 175″), as equal 9·8 mag.; the one at 168° : 240″ is, however, on the photograph about half a magnitude fainter than B, and the other at least a magnitude fainter. The bright star at 78° : 240″ is 9·6 mag., that at 245° : 250″ 9·8 mag., and the one at 356° : 172″ a little fainter than 10·0 mag. Σ. The star at 188° : 220″ is about 10·0 mag., and the remaining six seen by him range from 10·8 to 11·7 mag.

The paper by Prof. Asaph Hall, alluded to by "F.R.A.S." as appearing in the October number of *L'Astronomie*, is simply a *verbatim* translation (whether communicated or not by the author I am, of course, unable to say) of an article which appeared originally in the *American Journal of Science and Art* for March, 1885, and which was copied from thence into the *Observatory* for April, 1885. Dr. C. A. F. Peters's investigation appeared in *Ast. Nach.* No. 512 (1845); Dr. Magnus Nyrén's in his paper "Die Polhöhe von Pulkowa," and there is a paper by Mr. Downing on the subject in *Monthly Notices*, XL., page 430.

So far as I am aware, no Continental astronomer of any reputation whatever considers that the Nova of 1572 has a period of three centuries, or expects it within the next few years. I would refer "D. A." (letter 26415, page 190) to two letters on this subject by Mr. Lynn, which he will find in the *Observatory* for April and May, 1883, pp. 126 and 153. I may also perhaps remark that I briefly examined the evidence for the alleged appearances in 945 and 1264 in the ENGLISH MECHANIC for January 2nd, 1880. (Vol. XXX. p. 402, letter 16666.) Undoubtedly Leowitz confused the comets which actually appeared in 945 and 1264 with stars. There is about as much evidence for stars having appeared in the place assigned by Arg. and Hind to the Nova of 1572 in the years 945 and 1264 as there is for the identity of Nova 1572 itself with the star of the Magi. Statements of this kind are copied in popular handbooks of astronomy with parrot-like fidelity; the duty of verifying their quotations or investigating such matters for themselves, instead of copying blindly from one another, being one which is very lightly regarded by the authors of such works. Smyth says that Schuler first saw the Nova of 1572 on August 6th, and that Hainzel perceived it at Augsburg on the following evening. Lindauer undoubtedly saw it at Winterthur on November 7th, and Maurolycus observed it with instruments at Messina on November 8th. Tycho Brahe first saw it three days later. I notice that Prof. Pickering has discovered by his method of photographing stellar spectra that four more stars in Cygnus exhibit spectra crossed by bright lines. One of the new ones is the variable P. 34 Cygni (on which cf. *Observatory*, Sept., 1886, p. 314), and another is the red star Holden 186 (D.M. (+ 37°) 3821), alluded to in a note on the magnitudes of some stars on one of MM. Henry's photographs in the ENGLISH MECHANIC for June 25, 1886. Photographs of the spectra of stars near the places in which the Nova of 1572 and 1604 appeared would be of interest. The star supposed to be the Nova of 1572, A of the diagram on p. 402 of Vol. XXX. of the ENGLISH MECHANIC, is about 9½ mag., and its spectrum would therefore be bright enough to be photographed. As Dr. Hind once remarked to the writer, a further investigation as to the place occupied by Nova 1604 is desirable.

November 1. **H. Sadler.**

HOW TO WRITE THE D.M. STARS.

[26442.]—MR. SADLER called our attention to this subject in Vol. XLIII., No. 1106, p. 297. The following are the various methods commonly in use:—

D.M. + 21°, 576 according to Dreyer, Gore, Holden.
+ 21° 576 according to Schönfeld, Vogel, Dunér, the *Ast. Nach.*, and Pickering.
+ 21° No. 576 according to the *Observatory*.

The last must be adopted in the L. A. S. circulars in future, as it emanates from Greenwich.

Wolsingham, Darlington,
Oct. 26. **T. E. Espin.**

ALPHA ARIETIS.

[26443.]—IF "F.R.A.S." (letter 26389) will refer to the *Astronomical Register*, Vol. II. p. 54, he will see that the difficulty about Alpha Arietis has been discussed a long time ago. As far as regards the list of stars in Vol. I. p. 418, of the *Cycle*, employed by Smyth to test his objective, Mr. Dawes replied at p. 88 of the same volume of the *Register*. With respect to the supposed duplicity of Alpha Arietis, I beg leave to state that it is simply a typographical error for Epsilon Arietis, a well-known close double. This list of Smyth's tests is quoted in Loomis's "Practical Astronomy," pp. 25, 26 (first edition). Mr. Dawes's suggestion does not touch upon the difficulty of Loomis quoting Alpha as a light test at p. 24. At my request, the late Mr. Bird most carefully examined this star with his 12in. mirror, and failed in detecting any star at all answering to Loomis's 11th magnitude at 30″ distance. There can be little doubt it is an entire mistake. The three small stars following Alpha Arietis, mentioned by Smyth, *Cycle*, Vol. II. p. 52, were well seen by me with a 4in. refractor in 1864. **George Hunt.**

Alleyn Park, West Dulwich, Oct. 26.

ABNORMAL TELESCOPIC DEFINITION.

[26444.]—I AM glad to find, from letter 26413, p. 189, that Mr. Sadler has turned his attention to the matter of telescopic definition as affected by peculiar conditions of the atmosphere. From his intimate acquaintance with astronomical literature generally, and the exceptional facilities for unearthing observations that to most of us are practically inaccessible, his contributions are always valuable and deservedly appreciated. The letter alluded to is no exception to the general rule, and the extracts it contains are so insufficiently known that they will be new to most astronomical readers and observers. The various points raised are extremely interesting, and the whole subject of atmospheric influence on the performance of telescopes is one which deserves more attention than has hitherto been accorded to it.

My authority for quoting Sir W. Herschel was derived from that quaint old book of Dr. Kitchener's, "The Economy of the Eyes." The original is therein referred to as contained in Vol. XCIII. of the *Philosophical Transactions*, p. 217, &c. With regard to the phenomenon of triangularity in star discs, I do not think it can be considered that such appearance is peculiar to *refracting* telescopes, for I have repeatedly witnessed it during the past eight years, whilst using a large *reflector*.

The occasional spurious duplicity of stars is a very remarkable, though fortunately less frequent, effect. I can only call to mind one such case in my own experience, and that was in 1877 or 1878, when I was using a 5in. achromatic. It troubled me very much just then, as I did not know whether it might be due to the instrument, and I wrote to Mr. Webb about it, who told me that he remembered seeing something very similar to what I described. I have never seen it with the reflector.

W. G. Franks.

EGYPTOLOGY.

[26445.]—MR. HOWELL is mistaken (26417) as to the meaning of Genesis xv. 13, and Acts vii. 6. The latter is a mere repetition of the former, which says—"Thy seed shall be a stranger in a land that is not theirs, and shall serve them, and they shall afflict them four hundred years, &c. Also verse 16, "But in the fourth generation they shall come back hither again."

There is no vagueness in this statement. They were to go to some other place for 400 years, and return to that place afterwards. In the other place they were to be afflicted and made to serve others. Is it reasonable to suppose the writer meant to say that these people should spend half of the time mentioned in what he considered their own land, doing their own business freely? None but a theologian can think so, or some one quite under theological domination.

If Galatians iii. 17 contradicts Genesis xv. 13, then either must be wrong, and possibly both, as they differ from Exodus xii. 40 and 41, which says —"Now the sojourning of the children of Israel (mark the name, sons of Jacob) who dwelt in Egypt was four hundred and thirty years (not 400), And it came to pass at the end of the four hundred and thirty years, even the selfsame day (no vagueness here), it came to pass that all the hosts of the Lord went out from the land of Egypt." If Mr. Howell is right, Exodus should say: "Now the sojourning of the children of Israel who dwelt in Egypt was 215 years"; but it actually says quite the contrary. If Mr. Howell is right in his view of the time spent in Egypt, it is perfectly clear he ought to agree with me that reliance cannot be placed on Biblical figures, and I hope he will say so.

Galatians iii. 17 appears to be but a repetition of Exodus xii. 40, with a modification to get over the difficulty, which was probably known to the learned Jews at the time of St. Paul. The number of years mentioned is the same (430), but in one the date is from Abraham, and in the other from Israel The context in Galatians shows that Paul was not thinking about small technicalities, and would probably despise them, as he did genealogical questions (Timothy i. 4), which at present trouble many who intend to believe in the infallibility of the text. It would not be possible for Paul to claim certainty for his text, and the same for Exodus. He did not raise such a question; but it has been raised for us, and we must answer it somehow.

It is of no use asserting that one set of extracts settle the question, when the question is as to the veracity of the whole. If they contradict each other, it is absurd to say they are perfectly reliable.

Memnon.

[26446.]—MR. HOWELL necessarily finds a difficulty through a verse, Ex. xii. 40, which he is unaware is one of the few that the Jews of our first century managed to alter for the purpose of creating such difficulty. The Greek and Samaritan copies, out of their reach, retain the full text thus: "Now the sojourning (or proletariat) of the children of Israel *and of their fathers*, which they had sojourned in Egypt *and Canaan*, was 430 years." That rabbis who had the audacity to corrupt the chronology 16 centuries, by either altering or suppressing nearly every date of the forty between Adam and Abraham, should doctor chronological texts elsewhere a little, when possible, by only dropping two or three words, was to be expected. That the words were genuine, however, is plain by comparing the prediction, Gen. xv. 13, before Isaac's birth, that the promised seed should be afflicted 400 years. This began when Isaac in childhood was mocked and afflicted by Ishmael, and ended only at the Exodus, just four centuries after, but over six if you make the Egyptian bondage all the 430 years, instead of half.

A few other points essential to this Mosaic question, that seem utterly ignored, I would gladly hint at. The "Mosaic authorship of the Pentateuch" was a dogma closely resembling that Moslem one, that the Koran was never written, but existed in heaven from eternity. I am not sure that our clergy might not, by giving the claim that full extent, have strengthened their case. However, they have long abandoned it, and it only serves now, and may for ages, as a torture-instrument for such as "Memnon" to amuse themselves by goading such as "Ramases" with. Nobody decently educated now supposes any document older than it represents itself. There may be some parts of our Bible that can hardly be said to date themselves; but such is not the long narrative wherewith it opens, which is unbroken from Adam to the death of Samson, and plainly a single work, not seven. Sir Isaac Newton pointed out in nearly his last, and one of the carefullest of his writings, that this dates itself as frankly, and almost as definitely as any book whatever before dates were printed on title-pages. Gen. xxxvi. could not be written *before* all those generations of Edomites had lived, eight of their kings died, and a king reigned in Israel (v. 31); nor could Judges i. 21, *after* David took the stronghold of Jebusites in his eighth year. The composition limits itself to less than half a century at the very utmost, viz., Saul's reign and seven years after him; but this also fixes the authorship, or rather editorship, as it is plainly chiefly compiled from older books, many of which it names. The great prophet and judge, Samuel, must have issued it, because nothing so important could, in his time, have got credence but by his authority; moreover, hardly could anyone not so early devoted and educated as he in

those times have got the learning necessary to such a work. The materials had to be Hebraized from Moses' Coptic and various now lost tongues (though probably all Hamite) into that now called Hebrew, which was, as Isaiah calls it (xix. 18), the "language of Canaan," of the children of *that* son of Ham. Hebrews, we must remember, have never had a national tongue. According to Moses, they did not become a nation early enough. But as English is now the mother tongue of Jews born here, so were Greek and Aramaic those of Christ, so were Aramaic and Canaanite those of Ezra's people, but Canaanite alone of Samuel's, and Coptic of Moses. Their Canaanite literature, now the "Old Testament," was all produced between the times of Samuel and Malachi, which is no wider interval than divides us from Chaucer. But many Eastern tongues change less in eighteen centuries than ours in five. Modern Greeks, who can read no classic, are yet said to find less difficulty in the Gospels than we do in Chaucer.

Samuel, David, and their contemporaries, as Heman, Ethan, &c., then turned all the most venerable documents into Canaanite, as Job, the Seven Psalms of Moses, and many far older. What account can be given of two such psalms as those numbered for us 14 and 53, but that they are two men's versions of one original? The literary inferiority of the two books next the Pentateuch does not imply an inferior hand to Samuel's, but only scantier materials. He, as we read in I. Sam. x. 25, wrote "the manner of the kingdom, and laid it up before the Lord." The holy ark was then in Philistine hands, stripped doubtless of all its gold and more precious contents, and when afterwards placed in Solomon's Temple, a mere battered fetish, "there was nothing in it save the two tables" (I. Kings viii. 9), the granite slabs with the "ten words" in them "on the one side and the other," written (as is all native granite) "by the finger of God" (and wonderfully like old Coptic writing does any Sinai granite polished always look).

Now, the earliest books, nobody can suppose, were alphabeto-phonetic; but of the nature of our algebra, or Chinese or Mexican writing, and so may have been much of what Samuel interpreted for us, dating from Adam's time. Who could have pretended to keep such accounts as Gen. v. and xi. but in books of some sort? Both the Canaanite editions extant have plainly, in all those dates, been wilfully cooked, and differently, by two hands. It is not more Providential that the true numbers remain to us in the Septuagint and Josephus, than that the two corruptors should so contradict each other. The Jew altered the whole twenty generations down to Abraham; but the Samaritan was cunning enough to avoid clashing with other genuine chronology, by leaving those since the Flood untouched, to deal more impudently with those before it. (By "genuine," of course, I do not mean Manetho's, or any other of these lying Egyptians' self-contradictory rubbish that "Memnon" would import; but such as Chinese, Hindoos, Babylonians, &c., preserved, and that accord with the pleistocene geology). Adamite generations then, we learn, averaged a fifth of a life, or over two centuries, and the shortest over 160 years. Those of Shem's line to Abraham all exceeded a century; and one, Nahor's, the best reading gives 179 years; but if his son died before him, only the grandson Terah would be named. Thus I do not understand by the phrase, "Noah begat Shem, Ham, and Japhet," that these were his own sons; but three of his descendants—the only three (out of scores perhaps) whom he could persuade he was not mad. (He was Osiris, and Saturn, and Satyavrata—each of whom survived all his own children.) Now, as the immediate fathers of Shem, Ham, and Japhet were of those perverse "sons of God" who married mere "daughters of men"—of the short-lived flint-folk, and as these three saved ones would each have a wife of his mother's race, there is hardly ground to suppose even these (far less their children) were more alike than a Chinaman, European, and negro of to-day. Noah was the last Adamite "perfect in his generation," or pedigree (the last of those gods that Egyptian tradition painted red), and none since him can be of more than quadroon, or rather octoroon, Edenite blood; all of us of mainly flint-folk, and perhaps even of Hanahash, Eve's deceiver, who was doomed personally (not his posterity) to grovel on the ground. It was quite natural, too, for the lives of even the three Noah saved, to drop to about half his own Adamite longevity, and then, by further intermarriage, in Heber's time to a quarter, and finally an eighth. All the shortening of life was thus natural, even if the Deluge made no great atmospheric change; which, however, it doubtless did. A sudden precipitation everywhere of some 400ft. of water (for such all the traces attest) may well have added, too, so much azote, or oxygen, or both, as to change glacial climates to the present one.

Of course, Samuel had not the infallibity of modern critical history compilers. Probably his greatest mistake by far was embodying Gen. xx., which cannot be history, but a hash made of two incidents, what had happened to Abraham (ch. xii.), and a century later to Isaac (ch. xxvi.), and current, probably among the Moabites, as a tale to bastardise the whole Israelite nation. But it shows the extreme of error this scrupulous race could record there being neither a name nor a detail more than the two genuine stories gave; how far from aught like myth or legend, as generally understood!

Then there were places where details are left to the reader's common sense, as in the day of Hagar's dismissal. Of course, he who had been so generous to Lot, was equally so to his own concubine, and set her up as a Bedouin princess. Going with her and the lad, but having to part before sunrise, he appointed where the caravan of retainers and cattle he was about to send were to find them. But she lost her way near where Beersheba was afterwards built, and it was the heat of the afternoon, the luncheon and water spent, before they ("the shepherds," as Josephus calls them) did find her in distress. Another abused passage, Joshua's great miracle at Gibeon, might and ought, I believe, to be Englished thus: "Then spake Joshua to the Lord, in the day that the Lord subjected the Amorites to the Children of Israel; and he said in the sight of Israel, Sun of Gibeon, be silent, and thou Moon of Aijalon valley. And the Sun [oracle] became dumb, and the Moon [oracle] ceased, when the nation overcame their enemies. (Therefore is it written in the book of Jasher that the sun in the midst of heaven stayed, and hasted not to the west, about a whole day; and that no day was like that, before or after it, that the Lord attended to the voice of a man, because the Lord fought for Israel.)" The historian never quoted his contemporary Jasher as authority; but explains how the gross error of that poem arose. Though the Samaritan copy omits any miracle here, that of silencing those demoniac oracles was necessary, because the Israelites, having been cheated into an alliance with Gibeon, could not use violence against its temples; and unless the Gibeonite witchcraft were thus miraculously ended, it must have been perpetuated in the midst of the Holy Land.

Among proofs how genuine and ancient the materials for the Pentateuch must have been, there are two little details in the book of Numbers I never see noted. The matter comes from a generation who believed themselves more numerous than they were, and that is just what a multitude circumstanced like those with Moses would think; whereas their successors in any later generation would rather have minimised them, to show national progress (just as the fact that only 75 males had descended into Egypt was dwelt upon). Now we catch the exaggeration at its very root when we find in neither of the censuses any odd units, and in each only one tribe (Gad in the first, i. 25, and Reuben in the other, xxvi. 7) having odd tens. In each numbering, eleven tribes of the twelve have round hundreds. That implies they were numbered successively, and in each tribe, first those undoubtedly belonging to it. Then come those of doubtful pedigree, and at last some so uncertain that it became arbitrary with the numberers where to stop, which accordingly they did at a round number. So no fraction of a hundred got reckoned into any tribe till the last came. But even then, it was only odd tens, not units; and the reason for this we find on turning back to Exodus. In chapter xxxviii. 25, it plainly appears the counting was not of heads, but of money; the oft-told total of 603,550 (and presumably the other, 39 years later, of 601,730) being simply that of half shekels of silver, yielded by the poll-tax, required for every soul from a month old. Now, whether this was regarded as heavy or light will be plain enough on comparing it with the people's voluntary offerings, which had, as chapter xxxvi. says, to be restrained, almost like applications for Guiness's Brewery shares. The people brought more of everything than the plan of the tabernacle could find room for; but even of what was accepted, we find at xxxviii. 24 that the gold alone approached a third the weight of all the compulsory silver. This tax, then, was quite trifling, and as "there was not one feeble person among their tribes," every married man doubtless at once paid for ten, unless his household exceeded that number; in that cases for 20. If silver was coined at that early time, it was more likely to be in five-shekel pieces than in single or half ones, and then no tent would give less than one of those. In short, the 600,000 and odd was no muster of those "able to go forth to war," but simply (as Exodus shows) of those *paid for* as *possible*, and which the payers hoped might some day be able. But as the average household nowhere much exceeds five, this was probably not far short of double the full population, including infants; and any moderately attentive reader must have seen, long before Colenso, that the warriors, or rather married men of all ages, were certainly under 60,000, and probably much nearer half thereof. And had Samuel, or any later Hebrew, even Josephus, dealt with it like modern history writers, rather than mere compilers, they would have been anxious to minimise that multitude. **E. L. G.**

BODY FALLING FROM TRAIN IN MOTION.

[26447.]—Referring to Mr. Stretton's letter, page 194, the body does cease to be acted on by the engine, but the consequence is that its velocity neither increases nor decreases (but for the action of the air on it) and would remain uniform till stopped by contact with the step, and the body does travel by the side of the train till so stopped. The point where the body strikes the step depends on whether the train is moving with a uniform or an accelerated or a retarded velocity, and (2) on the force and direction of the wind. It is possible that, with a retarded train velocity and a strong wind in the direction of the train motion, the body will strike the step in advance of the point from which it fell. **J. S. C.**

[26448.]—In the correspondence in your columns on this subject, the writers seem to have overlooked the fact that, laying aside the resistance of the air, &c., there are two forces acting on the body. These are (1) the impulse due to the motion of the train, (2) that due to gravity.

Now, these two forces would constrain the body to take the same path as that of a particle, say, projected horizontally from a cliff—i.e., *a paraboloid curve*. Therefore, the moment that the body is dropped from the window the impulsive force of the train decreases, and the attraction due to gravity increases; so, that although the body would drop to the platform *behind* the point from which it was dropped, yet it would have described in its fall a parabola in the direction of the train's motion. This curve would be the resultant of the two forces above mentioned. I think if "Glatton" refers to "some elementary books on mechanics," he will find the correctness of my argument. **W. M. Potts.**

[26449.]—If Mr. Stretton chooses to assert (p. 195) when he is told (see letter 26400, p. 173), that the "resistance of the air is the sole cause" which could divert the falling body from a line which is vertical relating to the carriage, that "your correspondents refer to bodies let fall in vacuo," it is hopeless to attempt to convince him of his error.

In his next sentence he states the fact that a pistol let fall from the window of a carriage would fall on the footboard behind the point from which it was dropped, to be the sole question.

This is not, except in Mr. S.'s mind, the "sole question"; for no one has denied it as far as general conditions are concerned, although two cases are pointed out on p. 173 in which it is not true.

No, the sole question is whether Mr. Stretton was correct in asserting that the reason for this retardation was the law of falling bodies, by which, as I was careful to state, I understand the action of gravity.

I pointed out on p. 136, and more fully on p. 173, that the resistance of the air was the reason, and not the action of gravity.

On p. 155, Mr. S. admits that the wind would retard the falling object; but says this "would also tend to reduce," &c., evidently having the idea that inertia or some latent force which he does not name (query, gravity?) is the principal agent.

He is improving, however; for in his last letter there is no mention of the law of falling bodies, although he does not appear to admit that the sole reason for diminished velocity is that the air can act upon the body.

His question as to why the falling body does not travel by the side of the train, seems rather puerile. In the first place, because it does fall, and is stopped by the friction of whatever body it falls upon; in the second place, because of the resistance of the air which generally retards it while in the act of falling. If of same density as the air, and if the air was moving with and at the same rate as the train, the body would, as Mr. S. suggests, keep with the train.

I cannot think that Mr. S.'s having to trust to the lessons he learnt twenty years ago, is any reason for not knowing that the laws of falling bodies do not affect the horizontal component of the motion of a falling body, although, perhaps, a civil engineer who allowed such ideas to pass would not be too careful in correcting them. **Glatton.**

[26450.]—Perhaps the following remarks may make the matter a little clearer than it seems to be at present. If a person in a train is holding a pistol and lets it fall, it is evident that at the instant when the pistol is released it has the same forward velocity as the train. If nothing occurs to interfere

with the forward velocity of either train or pistol, they will evidently both travel onwards at the same rate, and the pistol will, therefore, strike the footboard immediately below the window. Now, as the pistol has been released from all connection with the train, there is nothing to modify its velocity except the (comparatively) slight resistance of the air, hence, if we neglect the resistance of the air, the pistol will travel onwards with its original velocity until it strikes the footboard. As far as the train is concerned, if the accelerating force of the engine is just sufficient to overcome the obstacles to the train's motion (such as friction, resistance of air, &c.), then its velocity will remain uniform; if, however, this accelerating force be increased or diminished, then the pistol will strike the footboard nearer the rear or the front of the train, as the case may be. Probably Mr. Stretton can tell us whether the motion of a train remains fairly uniform from one second to another, or whether it consists of a series of bounds, so to speak. I have been told that the latter is the case, but hardly think it is so. **C. W. Bourne.**

[26451.]—Mr. Stretton (26433, p. 194), no doubt knows the laws which govern this matter; but his mode of expressing them may very easily lead readers to suppose that he does not understand them.

It is, of course, true that "when an article is thrown from a train it ceases to be acted on by the engine"; but none the less it retains the velocity and direction of motion which it has already acquired from the engine.

The only way to understand this subject is to consider independently each of the several influences or forces acting. These are:—

(1) The action of gravitation, causing the body to fall vertically.

(2) The acquired momentum tending to carry the body alongside the moving train.

(3) The influence of the wind, including in this the friction of the body cutting through the air.

Each of these acts exactly as though it alone were in operation, and the ultimate point at which the body strikes is that which all three produce by their distinct actions.

Then comes in a new consideration. The body rebounds under a complicated influence, consisting of the actual motion it possesses at the instant of contact, and the elasticity of itself and the surface it strikes on.

It is obvious, therefore, that while the result is definitely produced by absolute law, it is impossible to predict that result, because we can never know or calculate all the varying conditions which come into action. **Sigma.**

IS VIOLET A PRIMARY COLOUR?

[26452.]—In his reply (26252), Mr. Reynolds still relies on his alleged synthesis by mixing blue light with a small amount of red, and on his supposed analysis of violet by means of coloured spectral images or "ghosts" projected upon a violet-coloured sheet of paper (or even the violet end of the solar spectrum), these "ghosts" having been impressed upon the retina by prolonged gazing at a red or blue object. Mr. Reynolds' mixed light can no doubt be separated again, by the prism or otherwise, into its original red and blue; and so also could the violet of his sheet of paper by the same means. But it appears to me that the question really is, Can the violet of the spectrum be so analysed? There can be no dispute that *to the colour-sense* violet appears to be a reddish blue; but in view of the well-known errors of that sense in judging of the nature of the colours yellow, blue, green, and, I may add, white, I do not think Mr. Reynolds should object to my treating with a little scorn its testimony regarding violet.

Mr. Reynolds' process of analysis by means of "ghosts" is founded upon the generally accepted theory of the production of these "ghosts"; which theory, as he says I do not understand it, he has been kind enough to explain at considerable length. Indeed, it has been familiar to me for very many years; and if it were a correct theory, I grant that it would perfectly serve the purpose to which Mr. Reynolds applies it. That it is not a correct theory I hope to show here more fully than space permitted in my first reply to Mr. Reynolds.

In the first place, we may dismiss as non-essential that part of it which supposes the visual nerves in the retina to be arranged in three distinct sets, each of which is appropriated to vision of one colour only, and direct our attention to the assumption that the colour of the "ghosts" for which the theory professes to account is derived solely from the light which the eye receives from the ground upon which the "ghosts" happen to be projected. In direct disproof of this I have already cited the fact that these "ghosts" may be seen upon a *black* ground, from which, of course, no light comes to the eye. Mr. Reynolds doubts this fact, having experimented in a certain way and failed to see the "ghost." If he will try the following method, perhaps the result will be different. Upon the lower part of a piece of black paper place two square pieces of brightly-coloured paper, their colours being as nearly complementary as can be procured (say blue and yellow), so that their upper edges shall be in line and their inner edges in contact. Now, after looking intently for some time at a point on the inner edges of the coloured pieces near where they touch the black, turn the gaze quickly on to the black. The "ghosts" of the coloured papers will now be seen projected upon the black; and being of complementary colours, placed side by side, they are more easily discernible than if either were presented alone. But besides the black background, coloured ones may be used which are defective in the very rays which usually form the colours of the "ghosts" which may be projected upon them. Instances of such backgrounds will be mentioned before I conclude.

There are several other phenomena connected with these "ghosts" which are also irreconcilable with the accepted theory. First, there is the fact that "ghosts" derived from objects viewed upon a white or light-coloured ground are always brighter or more luminous than the ground upon which they are projected. Now, according to the theory in question, the "ghost" ought always to be darker than the ground; because it is said to be due to the virtual absence from it of certain rays which the ground, indeed, supplies, but to which the observer has been rendered partially blind. In short, the "ghost" is said to be visible through defect of effective light. As the "ghost," however, shines with more light than the ground, I conclude that its extra luminousness must be due to something added to the impression received from the ground. This something, of course, is not light; but it is its equivalent—namely, a colour sensation impressed upon some part of the apparatus of vision in the process of forming the "ghost."

Second. Another phenomenon not in accord with the theory favoured by Mr. Reynolds is shown in the influence of the background on which the "ghost"-forming object is viewed upon the colour of the "ghost" projected upon another background. To illustrate this strikingly, lay a patch of black paper upon a brightly-coloured (say red) sheet of paper, and after forming the "ghost" of the black patch in the eyes in the usual way, transfer this "ghost" to a white sheet. Here the "ghost" will be seen to glow with a red colour (nearly but not quite the same as that of the ground upon which it was formed) surrounded by a green tint, which is, of course, the complementary "ghost" of the red sheet used in the experiment. Now, it cannot be said that this red "ghost" is the result of the eyes having been fatigued by gazing at a green object, for the object used was colourless black. A much deeper-coloured "ghost" is obtained if we use a white patch instead of a black one in this experiment. In this case, of course, the eyes receive from the patch a mixture of all the spectrum colours; but why they should elect to be fatigued only by the green remains to be explained. Perhaps it may be said that the "ghosts" in these instances appear red only by comparison with the "ghostly" green ground which seems to surround them; but I believe it will be acknowledged by all who try the experiment that the colour of the "ghosts" is far too positive and distinct to be so accounted for. I may mention that the "ghosts" thus produced have not the exact tint of the ground upon which the black or white patches are viewed in forming them, but one a shade nearer the middle of the spectrum.

Third. Another class of facts inconsistent with the theory that the "ghosts" are the results of partial colour-blindness in the observer is that already alluded to, in which "ghosts" are visible upon grounds of such colours that they cannot supply all the tints actually present in the colours of the "ghosts." A notable case of this kind is that mentioned by Mr. Reynolds, in which a blue "ghost" is visible upon a violet ground—a case which, to my surprise, he adduces as telling strongly against my explanation of the "ghosts." If Mr. Reynolds, instead of being satisfied with a purely hypothetical explanation of this phenomenon, will experimentally seek for its cause, he will be more likely to arrive at the truth regarding it. As thus: The blue "ghost" is the result, in the first place, of staring at a patch of red paper. The immediate effect of this first part of the process is that a *green* spectral image of the red patch is impressed upon, and for some time retained by, the eyes. This green "ghost" will appear still green if projected upon a white, black, or green ground, because there is nothing in the tints of these which can alter the green of the "ghost" when mixed with it. All other colours in the ground, however, are found to change that of the "ghost"; and they do this exactly in the manner in which we know by experiment that changes of tint are produced when two different coloured lights are mingled. Now when the green "ghost" is projected upon the violet ground, the result is the same as when we mix green and violet light—namely, the formation of blue; the green of the "ghost" mingling with the violet of the ground also forms blue, hence the blue "ghost" upon the violet ground. Mr. Reynolds is no doubt right in supposing that "a feeble spectral yellow resulting from exposure of the eye to pure blue light" would produce a white "ghost" rather than a red one upon a true violet ground. As this "ghost," however, in Mr. Reynolds' experiment appears to have been red, I am inclined to think his feeble spectral yellow must have had an orange tinge, or else that his ground was purple or lilac rather than violet. This latter point Mr. Reynolds can easily test with his spectroscope. If he will mix orange and violet lights he will get *a kind of red* analogous to his violet mixture of blue and red. These red and blue "ghosts" appear as comparatively light or bright patches upon the violet ground; and if they are held to be produced from composite violet light, it must be, not because the eye has been rendered insensible to one constituent of that light, but rather because it has acquired an abnormal supersensitiveness to the other constituent.

Besides these cases in which the colour of the spectral image combines with that of the ground to form the colour of the "ghost," there are others (to which I have already referred) in which the "ghost," like those seen upon a black background, is so vivid as to overpower the colour of the background altogether, and in which that background does not and cannot contribute any colour towards that exhibited by the "ghost." Thus, a red ground, which (as ascertained by means of the spectroscope) reflects neither yellow nor green light, may have "ghosts" of these two colours vividly shown upon it—the yellow "ghost" having been derived from a blue patch, and the green "ghost" from a red patch, both viewed upon a bright green sheet. This green sheet, of course, at the same time produces a red "ghost" of itself, which intensifies the red of the background upon which the yellow and green "ghosts" are exhibited.

Another point in which this ingenious theory of the colours of spectral images is contradicted by my experience, and doubtless by that of others, is the assumption that the formation of these images is a result of fatigue of the eye. In my own case, although I believe I have an exceptional facility in creating these images, I can truly aver that I never have the least feeling of ocular fatigue in doing so.

The foregoing rather lengthy attempt to refute a mistaken theory has left little space in which to notice the passages in Mr. Reynolds' letter in which he impugns what he calls my theory. (I disclaim having any theory on the subject.) To my suggestion that in a mixture of red and blue the red might be neutralised by the green constituent of the blue, Mr. Reynolds, in his first paragraph, objects rather captiously that red cannot be neutralised by green. Of course in strictness I should have said *bluish green* (which, however, is still a variety of green); but this bluish green contains that portion of the violet which Mr. R. seems to admit would complete the neutralisation of the red. Then he says it is not clear that *all* the green would be neutralised by the small proportion of red required. Whether all or only some of the green goes with the red to form the white, which undoubtedly dilutes the colour of the resulting mixture, it appears that so much of it does so that the remainder is too feeble to affect what I call the outstanding violet.

Mr. Reynolds' second paragraph I have already dealt with. In his third, he tries to establish a parity of assumption between his view of the nature of violet and mine as to the constitution of blue. Even if he succeeded in this it would be but a poor argument in his favour.

Admitting the statement in Mr. Reynolds' fourth paragraph that the effect of adding green to a certain blue is to make it still bluer, it is difficult to understand how this fact should tend to make him doubt the existence of green in blue. If it amounted to an actual disproof of that "hypothesis," as he calls it (as perhaps it does to his mind), of course it would strengthen his contention as to the effect of adding red to blue, because that effect could not be explained by supposing that the red neutralises the green of the blue if there were really no green present to be neutralised.

Mr. Reynolds' next two paragraphs deal with what are matters of mere personal opinion, founded solely upon the uncertain indications of the colour sense. A discussion of these could lead to no definite or useful result. I therefore pass on to his last paragraph, in which we are again among the "ghosts." Here he says that upon a blue ground, which, his spectroscope informed him, reflected abundance of green light (he does not tell us what were its other colour-constituents), he observed a green "ghost" after gazing at violet, and that upon a paler blue ground he saw a violet "ghost" after gazing at green. My own experience (which in the main is confirmatory of Mr. Reynolds') shows that, provided the proper tints of colour are chosen for the experiments, both green and violet "ghosts" are visible on the same blue ground. Of

course, Mr. Reynolds attributes his green "ghost" solely to the green light reflected from his blue ground; but the violet "ghost" he thinks must consist of a mixture of the blue of the ground with a rose-coloured spectral image derived from the white light, which no doubt dilutes the blue of the ground. Here Mr. Reynolds has surely made an unconscious slip. He explains the formation of the green "ghost" in his own fashion, and that of the violet "ghost" almost in mine. Can it be that in the latter explanation he could give an instance of a mixture of red and blue forming violet, while the former accorded better with the colour-blindness theory? Did his blue ground not reflect enough of violet light to form the violet "ghost"? Of course, I agree with Mr. Reynolds that the colour of the so-called violet "ghost" is partly composed of a reddish spectral image resulting from gazing at green. Similarly, I I hold that the colour of the green "ghost" is partly composed of a very green-yellow spectral image occasioned by gazing at violet. In both cases these spectral images exist ready-formed in the eyes of the observer, and do not require white or any other external light for their development. In proof of this, I appeal, as before, to the evident luminousness of the "ghosts" as contrasted with the ground on which they appear. There are, no doubt, cases in which the "ghost" is darker than the ground on which it is projected (Mr. Reynolds' darker blue "ghost" on a blue ground may be one of them). But these occur only when the spectral image is formed by gazing at a bright patch placed on a much darker background. The reason is that this dark background produces its own spectral image, which is comparatively light, and this serves to brighten the ground upon which the "ghost" is projected, so that the latter appears dark by contrast.

This may be shown by the following experiment: Place together a white and black sheet, with their edges in contact, and across the line of contact place a strip of bright colour so that one half of it lies on the white and the other half on the black. Then, after forming a spectral image of the whole arrangement by gazing steadily at the centre of the coloured strip, quickly transfer this spectral image to a white ground. Upon this the "ghost" of the coloured strip will now be seen lying, one half upon a brilliant white ground, the other half upon a dull grey ground, the white ground being brighter, and the grey ground darker, than the "ghost" of the strip. These white and grey grounds are the "ghosts" of the black and white sheets respectively.

In conclusion, I beg to offer one remark upon the colour sense in relation to green. Mr. Reynolds is of opinion that the popular notion that this colour is a compound of blue and yellow is founded solely upon experiments in mixing pigments. This I am inclined to doubt, and to hold that these experiments do no more than confirm the judgment of the colour sense. In my own case, at any rate, the colour sense shows every variety of green to contain both yellow and blue, as distinctly as it testifies that red and yellow are the constituents of orange.

Joppa, Midlothian. **Walter M. Hardie.**

NEW TELEPHONE TRANSMITTER.

[26453.]—BEFORE replying to "Linnæus" (query 60515), it may be well to make a few additional remarks in continuation of letter 26285, No. 1122.

There are several very good transmitters, and it is little use in adding to the number, unless the new instrument can do something more than what the old has already accomplished. But the question arises: Is there really anything to be desired in this direction more than what has been done already? The answer is: Very great improvements must be made before the telephone can be considered a satisfactory instrument for sending messages even over very short lines. How much has yet to be accomplished is best known to those who are in the habit of using the instrument. Besides, the problem of long-distance telephony is yet to be solved. Now in order to understand how far this new transmitter may be an improvement on the old forms—to what extent it deals with the problems of induction and long-distance transmission—it is necessary to study the action of the instrument itself. The first question that naturally arises is: What is the object of having two vibrators? The answer to this question cannot be stated in a sentence. The following features will, however, be sufficient to indicate the direction in which a reply may be given, as well as to point out the great utility of this transmitter.

1. Since the vibrators are similar and similarly acted upon by the sound waves that impinge upon them, the vibrations of the one assist the vibrations of the other. The action of the box and vibrating plates is to gather up and practically to strengthen the sound, somewhat as a tube would do, but with this important difference—there is no mumbling sound heard in the receiver, because the sound-waves are not entirely confined in the transmitter.

2. Since the vibrators act independently, the same message may be sent at the same time to two different stations—for instance, A at Birmingham can send the same message, at the same time, to B in London and to C in Manchester. Or A can converse with B in London, and with C in Manchester, at the same time. Or suppose A to be a "clerk in charge" at Birmingham; then B in London can converse, through him, with C in Manchester, should anything render the state of the line in such condition that A might take the part of telephone relay, and with this advantage—B knows whether the relay sends the message correctly, because he is listening while the message is being repeated to C. And, in the same way, C is listening while the answer is being sent to B.

3. Since at least four microphone electrodes may be placed on each vibrator, the same message may be sent at the same time to any number of stations up to eight. The utility of this does not appear at first sight, nevertheless it has an important bearing on the problem of long-distance telephony, and also on the question of induction. Further on it will be pointed out how "Linnæus" may perhaps be able to make use of this power to transmit to several stations with the same instrument.

4. Several batteries may be employed with this transmitter. The current from each may be sent along the same wire, or along different wires. Or the different wires and currents may be so employed as to form a protected zone round any particular wire carrying a transmitted message. A wire forming the path of a current may be said to be in a protected zone, when there is nothing in the space surrounding the wire that will change the character of the current passing over same.

5. Larger battery power can be used with this than with any other transmitter, which can be done without causing injurious sparking at the loose carbon contacts, and without lessening the electromotive force necessary for any distance or purpose.

6. The new transmitter may be called a duplex transmitter, or a multiplex transmitter, for by its means not only can the same message be sent at the same time to different stations, but the same group or system of vibrations, or undulatory currents, may be sent along the same line in successive intervals by one operation of the voice. For instance, a given undulatory current sounds R in the receiver; now, by sounding R once in the transmitter, two R's can be sent along the line, in such a way that the vibrations or undulations forming the one group follow the undulations of the other—the one group, as it were, clearing the line for the following group. The first undulations reaching the receiver may not give the required sound, while the following group renders the word intended.

7. A telegraph message cannot be sent across the Atlantic at the same rate as on a short line, and special means have to be employed to send a message at all. Could the telephone be used, the rate of transmission, with the aid of a shorthand writer, can be made fourfold. He, therefore, who wishes to send the first telephone message to America, has only to make use of a properly constructed duplex transmitter to enable him to do so. How to construct, and how to use, this duplex transmitter has been indicated in these letters.

In a week or two I hope to send "Linnæus" a short description, with sketch, of a simple, but most efficient transmitter. **Vibrator.**

CHAMBER ORGANS.

[26454.]—As Mr. George Landel particularly desires my opinion anent the question of wood stops for Chamber Organs, and says that he feels reluctant to go on with his organ until he hears from me, I hasten to reply to his letter in last week's issue.

I certainly felt somewhat surprised at his determination to use metal pipes only in his contemplated instrument, being under the impression that all past experiences had pointed to one conclusion, namely, the advisability of using both wood and metal stops in all organs. I am aware that certain organ builders have, of late years, advocated the exclusive use of metal stops; and I unhesitatingly affirm that a falling off in tonal quality has been the result of this stupid practice. One has not to look far for the reason of the practice. Wood pipes are more troublesome to make, and infinitely more difficult to voice, in a perfectly satisfactory manner, than metal ones; and an organ containing both wood and metal stops is more liable to go out of tune with changes of temperature, and, accordingly, makes greater demands on the tuner than an instrument entirely of metal. These are gains, certainly; but gains involving the sacrifice of beauty of tone, richness, and variety of effect. I wonder what the great Schulze would have said if any person had asked him to build an organ with metal stops only; but, then, he was a master of his art, and knew the value of, and how to voice, wood pipes. I remember a conversation I had with the builder of the largest organ in this country while I was examining the instrument in course of construction. He drew my attention, apparently with no little self-satisfaction, to the fact that he was using, with a single exception, metal stops throughout all the departments. I asked him, "What are you going to do for *wood tone* in the instrument?" He replied, "We can get wood tone out of metal pipes, and *better*." "Probably," I responded; "but it is the *better* that we do not want." I received no answer. The organ is a failure so far as general tone is concerned—at least, that is my opinion.

I strongly advise Mr. Landel to follow the good old school of organ building so far as the union of wood and metal stops is concerned. I know the value of the wood in my own organ too thoroughly to advise him otherwise. Mr. Landel says: "True, some of the wood stops are extremely beautiful, but I have yet to learn they cannot be imitated, or even surpassed, by those of metal." There is a striking parallel between the *and better* of the aforesaid builder and the *even surpassed* of Mr. Landel. Let me assure him we want, in a Chamber Organ, *the true wood tone*, not *a wood tone bettered*, or *even surpassed*.

Mr. Landel alludes to "several French builders who now only use metal stops." Of all modern schools of organ building let the French be avoided. The hatred of everything German must surely be warping the judgment of the French builders who have abandoned the eloquent teaching of the Schulze school. Let it be remembered that even the great Cavaillé-Col has never succeeded in building a decent Chamber Organ, and never will until he gives up many of his present ideas. It is satisfactory to know that all the great builders of the day are not blindly following this all-metal-pipe mania. The most renowned American organ builder—Mr. Hilborne L. Roosevelt, of New York—has assured me that he never intends displacing the wood stops, or attempting to introduce the *improved wood tone* from metal pipes. His organs present examples of wood stops unsurpassed in manufacture and artistic voicing by anything of the kind made in Europe. I have one beautiful example of his work in my own organ, a unison *Doppel-flöte*, which is, to the best of my knowledge, the first stop of its class ever introduced in an English organ. The *Doppel-flöte* is a covered wood stop, of German origin, consisting of pipes of oblong section, nearly twice their width in depth, with two mouths, one on each of the narrow sides. The tone is singularly full, rich, and refined in quality. When voiced, as in my organ, on a low pressure, it imparts much dignity to the tonal structure of a Chamber Organ. It occupies considerable space on the wind-chest, and that I am afraid would spoil its charm in Mr. Landel's estimation. I was content, however, to give it all the space it demanded, and have no cause to regret its insertion.

G. A. Audsley.

THE RED VARIABLE STAR V CYGNI—31 MESSIER ANDROMEDÆ.

[26455.]—YESTERDAY evening, at 6.30 L.M.T., I examined the beautiful red variable star in Cygnus, discovered by the late Mr. Birmingham on May 22, 1881, and situate 2° 51·7′ north of α Cygni. I find it is now at one of its minima, being about the same brightness as the twelfth magnitude star lying 60″ ± north of it; and a careful watch should be kept on it, being now favourably placed for observation.

In a letter of mine early this year in the "E.M." I gave some estimates of magnitudes at various times, and it would be desirable to have at least an approximation of its period.

After examining the above star, I turned the 4·3in. Wray equatoreal, with a power of 113, on 31 Messier Andromedæ, which I had not looked at since last spring, and, in the feeble light of the crescent moon, low down in the S.W., I was surprised to find that the nucleus of the nebula appeared to be much brighter than it was some months ago, being condensed into a blurred stellar aspect; but it had not the *double star* appearance I noticed when the nova was of the same apparent relative brightness as the nucleus twelve months ago.

In the *Astronomical Register* for this month (just to hand to-day) there is a paper copied from the *Astronomische Nachrichten* with an account of some observations made early last month on the Continent, where it was stated some apparent change in the nebula had been detected, and the nova was supposed to have again become visible; but the Kiel astronomers failed to detect any change a week later.

Belfast, 1st Nov. **I. W. Ward.**

LATHE MATTERS.

[26456.]—I HARDLY think a sketch is needed of the method of covering inner part of front bush. I should simply extend the boss till it neatly met the inner edge of bush, size the nuts to pass into it, and provide them with a loose annular cover of sheet metal, which could be held by slipping it on the boss, removing it when it was desired to set up

the nuts, &c. The nuts would, of course, have to be kept clean. The reversed sides are a minor matter, and each could choose his own style in case any subscribers care to make up the lathe or order it. The bottom slide could have the screw covered by adopting the American plan of a solid plate carrying the vees, with the nut carried down and under from the top slide. There is room for it, and it would do away with the need of increased clearance lengthwise, and stand heavier cuts. The bottom slide would then be a trifle more difficult to take apart; but that is not of much import. As the guidance of the tool from a rigid surface is desirable, I think both gibs on the top rest ought to be at the other side. In the case of the bottom slide, the gib could be attached by hexagon-headed screws, not countersunk, so as to leave no difficulty in tightening. In the case of the bottom gib of front slide, flattening the angle would not only ease the screws, but would also reduce the pressure on the surfaces, and increase durability and ease of travelling, reacting on the clasp nut and lead screw favourably. About 50° would be sufficiently acute for top vee, I think. The clasp-nut should at least be made to move side to side of saddle. The expense would not be great, while the improvement would, if the lathe were long, be an extension providing a socket still further to tail, and might advantageously be employed. Would not phosphor bronze be the metal for the bushes?

The size of mandrel "F. A. M." gives would do work of a larger size than 6in. diam. with fair cuts. I have a common lathe with each size of mandrel that cuts 13in. diam., and I believe would cut fairly on 18in. It runs rather stiffly at high speeds on small brass or wooden articles; but I run it much faster than is usual, with 7 to 1 gear, treadling at such speeds as will keep the treadle from flying when foot is taken off; 7 to 1 is easy enough, though my bearings are nearly half as long again as "F. A. M." proposes, being about $1\frac{1}{2}$ and $1\frac{1}{4}$in. long; 10 to 1 would not be too difficult treadling, I think. With regard to that important item, the mandrel, it should be noted that spring temper is not hard enough for the centring of the Edmunds model; in fact, the "J.K.P.," or well-finished screw centring, is the better fitted, as is also the male cone and ferrule attachment. The last seems to me the best for amateurs' own making, as spring-temper is not friendly to fine finishing of screw threads, and there would be least cutting to waste to get shoulder. A little increase in the overhang is the main defect of the cone, but everything else is more easily got.

Has "F. A. M." settled on his plan of loose-head? I hope that eventually we shall develop a good, serviceable, comprehensive lathe that will come into use and demand. **Vulcan.**

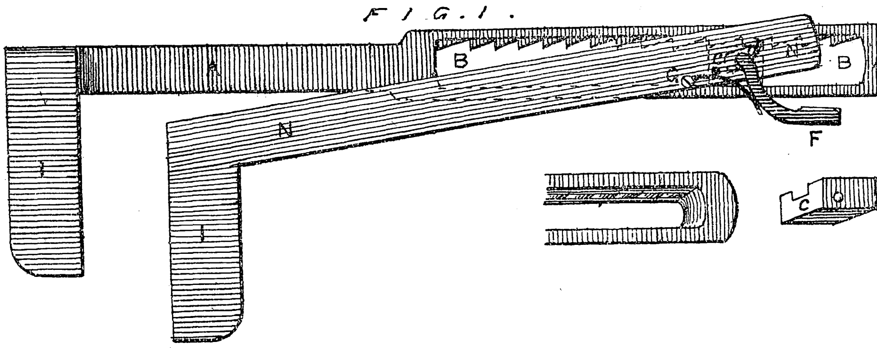
LATHE MATTERS—HOOKE JOINTS, SCREWING DEVICE, &c.

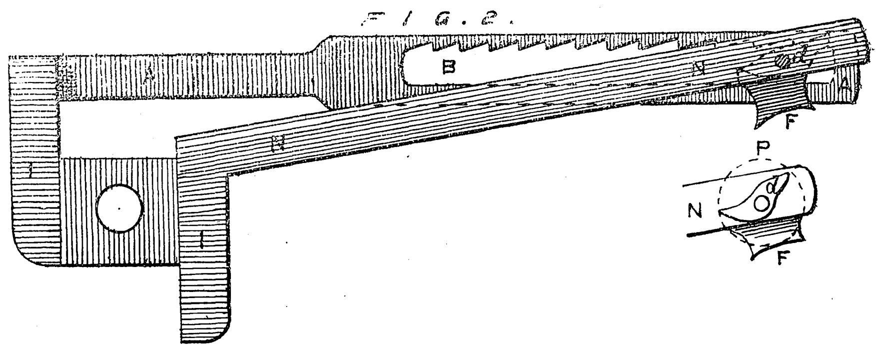
[26457.]—Referring to "Glatton's" remarks on page 191, I have no doubt that he is right in saying that forks of the intermediate shaft ought to be in the same plane: it is an important matter, and I am very glad he was good enough to point it out. Would it take up too much time and space to give the demonstration of what he tells us? Though I think I see that what "Glatton" tells us is right, I do not feel able to prove it. Moreover, though the inequality would be corrected where the first and third shafts are parallel (as they would be when using the long slide upon a flat surface or a parallel cylinder), and we could, therefore, cut true screws and flat surface spirals, I fear the result would be unsatisfactory if a spiral were attempted upon a cone. Mr. Evans uses the Hooke joints in this way, whilst Holtzapffel uses, I believe, spherical wheels, possibly to obviate this disadvantage. Also the pair of Hooke joints are used on the American milling machines, and therefore they must produce incorrect spirals when these are cut with the "spiral bed" placed obliquely, and therefore the spirals of all twist-drills must be inaccurate. I had my doubts about the matter, but supposed I might safely follow the milling machine.

The screwing device sent by "W. E. D." is, I think, the simplest I have seen. I know that the little cutter will work beautifully. Removing the work to the "nose" on the screw will be sure to make it run "out" a little, and cut the thread deeper on one side than the other. The nut C and the guide screw B will require to be very long. I would have the nut made in two parts, mounted one at each end of a T 6in. long, which T might fit into the rest-socket; the screw B might then be 7in. or 8in. long. The work could be fed up to the cutter by rapping the sole of the rest-socket with a hammer. Probably the chaser would remove the inequality of depth of thread. **F. A. M.**

ADJUSTABLE SPANNER.

[26458.]—I venture to inclose you drawings of an adjustable spanner, which appears simpler and more handy than the one figured in No. 1,126, p. 166, insomuch that it has fewer parts, and also that, after giving a turn to the nut, the jaws loose their hold of it, thus avoiding the necessity of removing the wrench to get another hold on the nut.





This wrench consists of a long arm, A A, with a rack screwed into a slot, B B, leaving about $\frac{1}{4}$in. of plain metal on each side of rack, whereon the sliding block *c* runs, which block has a catch, *d*, to engage in ratchet teeth.

The shorter arm N N is pivoted at E, which pivot also runs through thumb lever F, sliding block *c*, and catch *d*, and is secured on the other side by a suitable nut. The catch *d* is kept against ratchet teeth by spring G, which presses against thumb lever. Both arms, A A, N N, are provided with suitable jaws, I I.

If, for example, you wish to turn a nut, press down lever with thumb and slide short arm N N along, till the jaws I I grasp the nut. On the forward stroke the jaws grasp and turn the nut, but on the back stroke N N falls away a little, and slips round the nut. On another stroke being taken, the jaws again close on the nut.

Fig. 2 is the same wrench, but simpler, where the finger must keep the catch in the ratchet teeth by pressing lever up. **J. C. W. Kershaw.**

GLASS FOR THE WIMSHURST ELECTRICAL MACHINE.

[26459.]—In my former letters I have always endeavoured to press upon your readers the great necessity of testing the quality of glass about to be used for electrical purposes, and now for the information of so many as may also be the makers of electrical machines, I may state that, notwithstanding my full knowledge of the necessity of testing, yet I have fallen into the trap. It occurred in this way. I was wanting a considerable number of discs, and before buying I obtained and tested several samples of glass. The results not being satisfactory, the dealer then obtained for me a case of the "Bell" brand quality. From this I again made tests, and found everything to appear to be as I wished. The natural supposition was that the many samples tested fairly represented the quality of the whole, and I proceeded to cut thirty discs from the flattest of the sheets. It was only when the machine was finished that the truth became manifest, for then out of the first eight discs put into use three were of such bad quality glass that not only did they refuse to work, but, further, they conveyed away nearly all the electricity produced by the other discs. Of course, the three bad-quality discs have had to be replaced by others.

The lesson is that testing by sample is not sufficient. Each disc ought to be separately tested before being put into use. **J. Wimshurst.**

ZINC AND STEEL PENDULUMS.

[26460.]—Before I answer Mr. Buckney's letter published in your paper of the 22nd October, I would ask you to allow me space for a few lines, not bearing directly on the difference of opinion between Mr. Buckney and myself.

Most people know that clocks with ordinary pendulums will go slower when the temperature is hot than when it is cold; therefore it is necessary, in order to obtain correct timekeeping, to construct the pendulum in such a way that, for the purpose of timekeeping, it is under all changes of temperature of the same length—that is, the distance between the centre of suspension and the centre of oscillation should *always* be the same.

There has been constructed a large number of different kinds of compensation pendulums, but only two kinds have been generally adopted all over the world—that is, the so-called mercurial pendulum, and the pendulum made of zinc and steel tubes or bars.

In order to have correct timekeeping, the different parts of the compensated pendulum *should act at the same time*. That is the most important point in a compensated pendulum, and a point I beg to be remembered, because that is where the difference is between Mr. Buckney and myself. Mr. Buckney denies the truth of two of my statements—namely, that the mercurial pendulum used and described by him is badly constructed; also that that kind of pendulum is superseded long ago.

Anyone taking the trouble to think over the matter one moment will see at once that my argument does not admit of a doubt; it is as clear as daylight. The mercurial pendulum used by Mr. Buckney, would probably have a steel rod less than $\frac{1}{2}$in. in diameter, and a solid column of mercury about 2in. in diameter and not less than 7in. high. Supposing there is a rather sudden change of temperature, the comparatively thin pendulum-rod will certainly contract or expand long before the large column of mercury, and such a pendulum is, therefore, badly constructed. The object of my letter was to point out that Mr. Buckney had not proved by his paper published that mercurial pendulums were bad on the whole.

To make a mercurial pendulum with the bob of iron or steel with the pendulum-rod screwed in the top is a very objectionable construction—the temperature only acts on the outside of the cylinder; besides, the whole bob having to be turned to regulate the clock, would most likely affect the beat of the clock at the same time.

The second statement, that that kind of pendulum used by Mr. Buckney has been superseded long ago, could perhaps more correctly be stated that they have never been adopted. I may not trespass upon your valuable space any longer; but should Mr. Buckney, or anybody else, favour me with a call at 23, Great Portland-street, I shall be most happy to show them a mercurial pendulum superior to the one used by Mr. Buckney. **Christian Lange.**

SAFETY-LAMPS.

[26461.]—I am glad to see that this subject has not been dropped, and that two more letters have appeared.

I have not yet seen the Morgan lamp; but I notice that Mr. Shippey (letter 60634) says that it is simple in construction. I should not have thought so from the letters of "Practical" (page 179) and W. Clifford. The former speaks of it as "complicated," "too many parts," and the "short life of the gauzes," &c., and the latter mentions that the lamp has "four gauzes."

I happen to know Mr. C. E. Rhodes, and, thanks to his courtesy and kindness, I have inspected his

testing apparatus and witnessed some of his experiments.

I believe he has had a McKinless lamp under examination with good results; but I should like to know particulars. I always noticed the *bright* condition of the gauzes at his collieries, and I believe they are brushed with flint-dust. It would be interesting to know whether this does not soon alter the size of the mesh, and if to a dangerous extent.

Mr. Shippey asks why I object to wire gauze? I reply that I don't consider it reliable. I have no belief in uniformity in the mesh, as I have, under the microscope, been able to detect great differences in make and mesh, and, from the very nature of the material, it cannot be very durable, and when *properly* cleaned soon wears thin.

Only yesterday I used the McKinless lamp for several hours in the pit, and also tried it in fire-damp, and I can only say that I was thoroughly satisfied with its performance. It went out instantly in gas, gave a capital light, and did not get too hot. **Henry Palmer.**

East Howle Colliery, viâ Ferryhill,
October 29th.

HORSE-POWER AND MEAN-PRESSURE DIAGRAM.

[26462.]—If this identical diagram has been previously published, of course I have no "rights" to reserve.

Like "A Twelve Years' Subscriber," I have many similarly-shaped diagrams for various purposes of my own design; but excepting that some of them are composed of straight lines arranged in a triangular form, they cannot be called similar, as they serve different purposes.

"A. T. Y. S.'s" diagram appears, from his somewhat meagre description, to give nothing but the mean pressure, and apparently not even the effective mean pressure.

I have given both these and also the horse-power, and afford facilities for directly comparing engines with different back-pressures as well as different initial pressures.

Will "A. T. Y. S." give the name of the publisher of his diagram? **C. H. Wingfield.**

A GOOD BATTERY.

[26463.]—The following details of a primary battery test will probably interest some readers of "Ours." The cells were constructed with the object of obtaining a constant current of about three ampères over a long period of time, and are my own invention; the test was conducted by a Doctor of Science well known in London, and I did not even see the cells after I had charged them.

A few experimental tests were first made to ascertain the internal resistance, total capacity of the cells, &c., and then sufficient resistance was placed in outer circuit (which was not altered during the whole of the test), and a current of 3·45 ampères per cell was taken. The following extracts from the table of results will show the constancy:—

At start	3·45	ampères
11th hour	3·45	"
50th hour	3·45	"
98th hour	3·30	"
122nd hour	3·13	"
155th hour	2·27	"

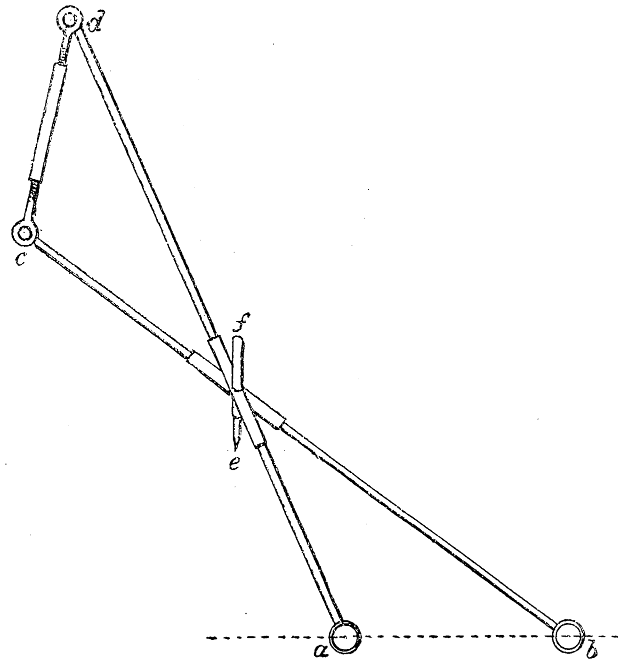
The E.M.F. was slightly under one volt per cell, and up to the 130th hour only fell eight decimal points. The actual internal resistance was ·087 ohm per cell at starting.

A cell was then tested for local action. After being short-circuited for 9½ hours, the positive plate was weighed accurately and replaced in the cell. At the end of eight days it was again weighed, and was found to have lost only 3·80 grammes, or practically *nil*.

I should like to have the opinion of some of "our" electricians as to its value for the vexed problem of household lighting; and as commercially these figures are of no value without actual cost, I may mention that a battery giving 63 volts and 12½ ampères constant for 126 hours would cost 30s. for the term, or under 3d. per hour for the electricity evolved. I shall be happy to give any further particulars to those interested. **Cato.**

A NEW ELLIPSOGRAPH.

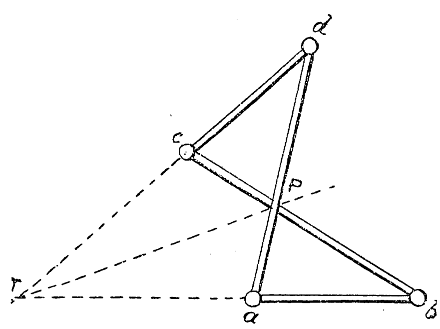
[26464.]—In the English Mechanic, page 167, you have an extract from the *Journal* of the Franklin Institute, describing a new ellipsograph designed by G. B. Grant. I write to say that three years ago I devised and constructed, *not only* the same thing, but also the improved form with sliders, which he suggests might be added, a rough sketch of which I inclose herewith. The pencil *e* is fixed in a socket, which is fast to the under slide; the handle *f* is similarly attached to upper slide. The link *c d* is formed in three parts—i.e., a socket screwed through half its length with a



left-hand thread, and through the other half with a right-hand thread, into which are screwed the two joints working on the ends of the links *a d* and *c b*. If the socket is turned one way the link *e d* will be shortened; if it is turned the other way, it will be lengthened to suit any required foci. **J. Riley.**

[26465.]—Mr. G. B. Grant's ingenious ellipsograph, figured in the last number of the "E. M.," (22nd October) was published some years ago in the *Educational Times*, but I have not the reference by me.

Mr. Grant does not do full justice to all the capabilities of his construction (which ought, I think, to be given in elementary books) as will appear from the statement below, and the accompanying diagram.



If the points *a b* are fixed, and the frame is made to move round the fixed link *a b*, P is the locus of an ellipse having *a b* for foci, axis major = *b c*, eccentricity = $\frac{a\,b}{b\,c}$: also T P (the line joining P to T the intersection of *a b* and *c d* produced) is a tangent to the curve at P.

If, instead of *a b*, the link *b c* is fixed and the frame moved about it, T will be the locus of a hyperbola having *b c* for foci, transverse axis = *b c*, eccentricity = $\frac{b\,c}{a\,b}$, P T a tangent to the curve at T, and the asymptotes will be parallel to that position of the links *a b*, *c d*, in which they are parallel to one another. **E. J. L.**

POLARISATION AND LATENT LIGHT.

[26466.]—When a ray is reflected or refracted it always loses more or less brightness thereby; but the loss is much greater for some angles of incidence than for others. And that angle which the ray must make with the surface, so that the loss of brightness is the greatest possible, is called "the angle of polarisation."

A single refraction can only partially destroy the brightness; but a second refraction is capable, on the one hand of totally destroying it, or, on the other, of restoring it almost to its original state. The following arrangement of prisms, though probably not the best for purposes of polarisation generally, seems best adapted for showing the extremes of the variation which the brightness may undergo.

Take two equal prisms, having one angle equal to the polarising angle, and it will be convenient, though not necessary, to make the sides containing the said angle squares. Place one of them so that a ray shall fall upon it at the polarising angle, in which position the loss of brightness by passing through it will be a maximum. Then place the other against it, with the square faces coinciding, and in such a position that the two shall together form a *plate*. In this position the brightness lost by passing through the first will be in great measure restored.

Finally, turn the second prism round through 90°, keeping the faces in contact as before. In this position no ray will be seen to emerge from the second prism. The question, therefore, will be asked, "what has become of it at all?" The answer which first presents itself is, "why, of course, it has ceased to exist." But this view, like many others which may at first sight present themselves, may certainly be shown to be fallacious. It will be found that the ray, instead of being improved out of existence, as is generally supposed, *has only been rendered latent*, and may easily be rendered again visible.

To do this, take a third prism, similar to the others, and place it in contact with the second prism, and in such a position as to form a plate with it: the ray will again reappear. And that it will do so is evident, even without special experiment. For, as happens in the first case, the brightness lost by passing through the second prism will be in great measure restored when another prism has been applied to it so as to form a plate with it. Now had the ray been reduced to non-existence by the first two prisms, it is self-evident that no addition of another prism could possibly make it visible. From which we conculde that it has only been rendered latent.

By latent light then we mean light which exists without being perceptible to the senses. And in this respect it bears a close analogy to heat, which is sometimes latent in like manner.

Now if it is asked, "what does latent light consist of?" the question will best be answered by seeing, first, what it is that common light consists of, and, next, what it has been deprived of by passing through the two prisms. What remains of it will be latent light. We may give an explanation as follows:—

Common light has been supposed in letter 26251 to consist of three sets of vibrations, one of them longitudinal in the direction of the ray, and of transversal ones, which may be resolved into two sets—the one of them in the plane of incidence, and the other perpendicular to it. After passing through the first prism, it is admitted on all hands that there is no longer any transversal vibration in the plane of incidence, and after passing through the second, there is no transversal vibration at all; so that there remains only longitudinal vibrations. These, therefore, are what the light must henceforth consist of, and as they are not evident to the senses, the light is latent. It may be noted that the light does not become insensible through the smallness of these vibrations, but from their being of a nature not to affect the eye with a sense of light, however large they may be, unless there are transversal vibrations at work, the action of the two kinds being explained in letter 26361.

We may now see how it is that the third prism makes the ray become again visible. If, as is

commonly supposed, there are no longitudinal vibrations, and the transversals had been removed by passing through the prisms, the ether would be reduced to a state of quiescence, and the ray would simply have become non-existent, and could not reappear. But from the ray becoming again visible through passing the third prism, it is evident that there must again be transversal vibrations.

We are now able to give a simple account both of the disappearance and the reappearance of the transversal vibrations, both of which facts would be wholly inexplicable, but for the existence of longitudinal vibrations. The case is simply one of the composition and resolution of motion. The longitudinal vibrations in the latent ray are resolved into longitudinal ones in the ray refracted through the third prism and transversal ones, as is shown by the reappearance of the ray; while on the other hand, the longitudinal and transversal motions which exist in the original ray become compounded into longitudinal ones only in the refracted ray.

The three prisms, therefore, show the existence of the three vibrations; the two first of the transversal, and the third of the longitudinal. Three mirrors properly placed would doubtlessly show the same.

In the next letter we shall try to show why the angle of the prism should be equal to the polarising angle. **W. G. Penny.**

(*To be continued.*)

THE CONTINUOUS BRAKES RETURN.

[26467.]—The return relating to continuous brakes in use during the first half of the present year has recently been published by the Board of Trade, and it confirms the opinions expressed at the Congress as to the very unsatisfactory state of the brake question.

The following table gives a summary of the rolling stock fitted on the 30th of June, 1886:—

—	Engines Fitted with Brakes.	Engines Fitted with Apparatus for Working the Brakes.	Carriages, &c., Fitted with Brakes.	Carriages, &c., Fitted with Pipes or Chains only.
Total amount of stock returned as fitted with brakes which appear to comply with conditions of Board of Trade	2,604	1,376	22,230	4,623
Total fitted with brakes which do not comply..	1,216	1,435	13,111	3,274
Total fitted	6,631		43,238	
Not fitted with continuous brake	849		8,552	
Total passenger rolling stock therefore	7,480		51,790	

From these figures it will be seen that out of a total of 7,480 engines and 51,790 vehicles, only 2,604 engines and 22,230 vehicles have brakes which even "appear" to fulfil the conditions laid down by the Board of Trade, and from my recent examination of all the systems I find that several returned as efficient are not really so in actual practice; and in the return, page 28, the Board of Trade add a note that "These totals are the numbers of engines and carriages returned by the railway companies as fitted with continuous brakes. It will be observed, however, that some of the brakes so returned but very imperfectly fulfil that designation." Since the Railway Servants' Congress I have, as an officer of the Amalgamated Society, carefully examined the brake return which has lately been issued, and the result is that I find it so full of incorrect statements that for all practical purposes of comparison it is absolutely useless. Brakes are included in the list of those which "appear" to comply with the conditions, which do nothing of the kind. The Board of Trade return shows 1,376 engines fitted with apparatus only, and 4,623 vehicles with pipes as appearing to comply; but, in fact, this rolling stock does not fulfil any condition. What possible brake power can there be when an engine has simply the *apparatus* for working brakes on trains, but no brake-blocks upon its wheels? or what value can a train of pipe vehicles be in case of accident?

I have now before me details of a case where a train was sent out with an engine with no blocks on its wheels, and 18 vehicles, 14 of which had through pipes only. Such a train would be returned to the Board of Trade as working a certain number of miles with a continuous brake; but, in fact, it was in almost as bad a position, so far as stopping goes, as a train without such a brake, and so long as horse-boxes, fish trucks, and other vehicles are run in passenger trains, it is essential that they should be provided with the continuous brake gear complete.

The returns relating to "failures" are as usual very incorrect: a large number of cases are not reported at all, and others are either placed under the wrong headings or even charged to the wrong brakes. It is also important that the companies should be required to furnish the *name* of the place where the failure occurs, as without this information it is impossible to trace a case or to know if it is reported or not. The Metropolitan Company, for instance, gives about a page of cases in which "a train overran the platform of *a station*." The Great Eastern and Glasgow and South-Western also omit the names of stations. The Lancashire and Yorkshire Company report an actual failure to act on February 25, at Hindley, simply as a delay, whereas it is a case which ought to have been recorded under Class 2. The same company records ball-valves and vacuum apparatus out of order, as belonging to the Westinghouse brake.

The Midland Great Western of Ireland also reports three actual failures of Smith's vacuum brake as simple delays.

The simple vacuum brakes *failed to act* no less than 71 times in the half-year, and in three of these instances collisions were caused—namely, at Kirkstead, Sutton Coldfield, and Birmingham.

The policy of the London and North-Western Company in removing the chain brake and substituting the simple vacuum is most unsatisfactory, and is but a waste of the shareholders' money, as without doubt it will at some future time have to be altered or removed.

For some years it was urged by some companies that the adoption of good brakes would cost too much. This cannot now be urged, for it is a fact that enough money has been spent and wasted upon fitting, altering, and removing inefficient brakes, and upon fitting two systems to one vehicle, to have provided every vehicle in this country with a good continuous brake.

Railway servants and practical men of course know that no brake has ever been invented equal to the Westinghouse in efficiency, and those who desire to see safe railway working must necessarily regret that it was not years ago adopted as the brake of this country, as hundreds of lives and thousands of pounds would by this time have been saved.

It is now perfectly certain that the companies never will settle the brake question until forced to do so; therefore it is to be hoped that Parliament will deal with the subject as early as possible, and before any more fearful accidents occur.

Leicester. **Clement E. Stretton.**

RAILROAD FARES.

[26468.]—Outlay of capital has something to do with railroad fares; hence perhaps the following table will be hardly less interesting to subscribers than that lately communicated by "H. B. F." (26395):—

Comparative average outlay of capital on English and foreign railways, as proved before the Select Committee on Railway Rates and Fares, 1881-2.

	Per Mile.
Great Britain	£40,000
France	32,800
Austria	21,000
Germany	20,500
Holland	20,000
Belgium	20,000
United States	11,800
Denmark	10,120
Norway	6,490
Sweden	6,401

Again, State railways, State guarantees, and subsidies are common things abroad, whereas there is nothing of the sort in Great Britain.

C. J. Tahourdin.

"Baynards," Wallington, Surrey, Oct. 26.

RAILWAY SIGNALS.

[26469.]—I have been laid up. Mr. Stretton appears to doubt my veracity. It would be useless for me to adopt a nom-de-plume and give the name of the railway for the signalling of which I am responsible; and with regard to the examining of the signals, referring to the concluding paragraph in Mr. Stretton's letter (26425, p. 193), I am afraid some of the readers of the "E. M." will come to the conclusion that "Libra" is one of the aliases of Mr. Stretton's detractor. Would you be kind enough to verify my address by a directory and note at the foot, not the address, but that it is correct? **Libra.**

[We cannot undertake any responsibility of the kind.—Ed.]

REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[60196.]—**Locomotives (U.Q.)**—Caledonian engine No. 128 (Class 125—129) 4-coupled: wheels, 7ft. 1in.; cylinders, 18 × 24; number of tubes, 186; weight, 41½ tons.—A. J. H.

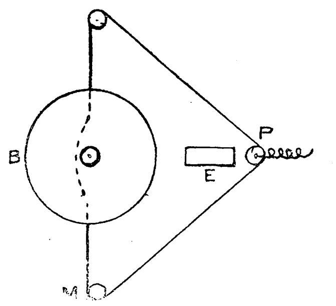
[60216.]—**Mineral Waters (U.Q.)**—As this puestion has remained unanswered, I have cut out the following from my "System of Hygienic Medicine," pages 66 and 67. It partly answers the query:—"Many believe in mineral waters. They say they are at least natural (i.e., to be used medicinally by man), and will alleviate our ailments. Now, is not this absurd, for mineral waters are the results of well-known conditions. The earth is composed of about fifty different metals, scattered more or less in the substance of the globe. Water is evaporated by the sun from the land and sea; it forms clouds, these in time break in showers. The rain has absorbed some carbonic acid in the air, it falls on the earth, and, percolating through it, dissolves some of the substances that it comes in contact with. In limestone districts the water is hard, because the rain, containing carbonic acid in solution, dissolved some of the lime from the rocks it came in contact with. If the soil contains any soluble salts, then the water dissolves these and is impregnated with them. Underneath the ground, water collects in large reservoirs or beds, and will then be forced upwards at one spot by a well-known natural law. This is a natural spring, and according to the rocks in the neighbourhood so will the water be. If pure limestone, then we get a hard water. If iron is in the soil we get ferruginous or chalybeate springs. If salt beds are under the soil we get salt springs, as at Droitwich; if the spring is in a metaliferous district we get the salts of iron, arsenic, lime, soda, magnesia, lithia, &c. This, in plain fact, is the way our medicinal springs arise, and as long as the medicinal, or drug, treatment of disease is reckoned good, so long will they be looked upon favourably. There is plenty of water in the world, some wholesome, like pure spring water, some not, like sea water, or water contaminated with mineral salts. There are a few good natural springs, such as those of Malvern; here the water is about the purest that can be drunk next to distilled water. This water carries little mineral matter to the system, but can carry a lot of waste material out; hence it is useful in gout, rheumatism, and other diseases. Many persons derive undoubted benefit from visits to places where there are springs, but this must not be put down to the waters drunk. We must reckon first the change of scene and possibly a purer air, absence from the worry of every-day home life, or absence from business cares; perhaps a simpler diet and more regular hours. Then there is the object in going there, and the banishment of ennui in seeing the company, listening to the bands, going picnics, in mixing with new faces, and getting new ideas of people. These and many more little items most often account for the good done by visits to mineral springs."—T. R. Allinson, L.R.C.P.

[60275.]—**New Banjo.**—If "Sam Koe," who gave such a good description of the "Dobson" banjo in reply to this query on page 157, would favour me by giving particulars of the "silver one of the latest pattern for 5 strings," which he speaks of in his reply, I should be extremely obliged to him.—Black Bones.

[60306.]—**Photographic Engraving.**—Mr. Roper does not indicate in what respect he failed; but I think he will find that the gelatine which has been unacted upon by light must be washed away in a dark room before the plate is placed in the etching bath. The advantage of using copper plates is not quite clear, for zinc is much cheaper and has been adopted by most of the skilled workers who now produce "process blocks." Mr. Roper might read a letter on p. 509, last volume, and an article on "Zincography," which appeared in No. 1,074, p. 155. He might also find some useful information in the book noticed by you so recently as Oct. 8, p. 123.—Saml. Ray.

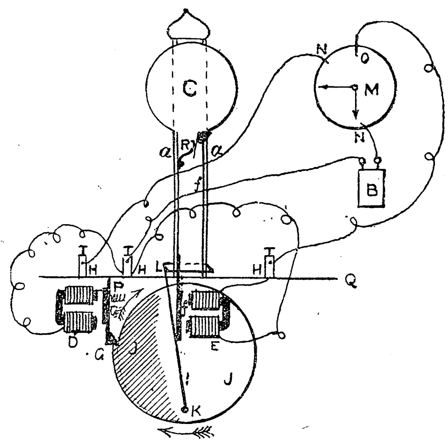
[60316.]—**Electric Time Ball.**—The following is the simplest method I have been able to devise:—B is the hollow ball with a piece of tube across a horizontal diameter. It has a hole at the top and at the bottom through which a cord passes. M is a self-starting electromotor having on its spindle a ratchet wheel which allows it to run in one direction only. P is a pulley, which, by means of a spring, stretches the cord tightly. It has an iron block attached to it. E is an electro-magnet pulling in the opposite direction to the spring. Two or three minutes before the hour the clock completes the circuit of the motor, and the ball is slowly raised. The friction of the cord on the tube in the centre

of the ball prevents its falling. At the hour the electro-magnet E, acting on the armature attached



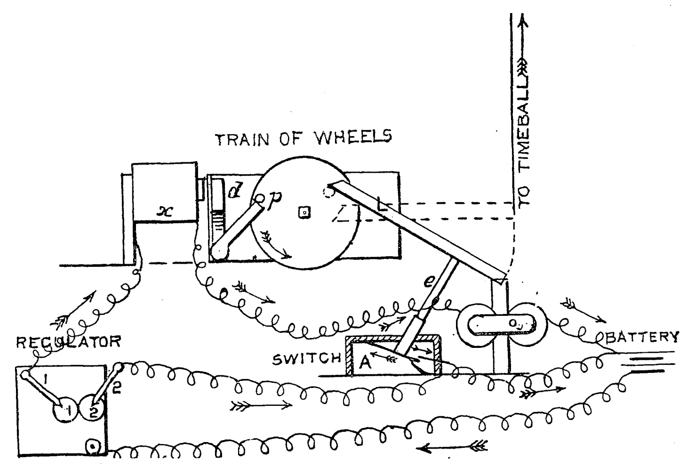
to P, slackens the string, and the ball falls.—G. BOWRON.

[60316.]—**Electric Time Ball.**—Some years ago I successfully constructed a time ball to rise and fall. Particulars as below. The sketch is obviously not made to scale, but is drawn to make details as plain as possible. *c* is the ball fitting round the upright (*a*) which has a groove cut up to receive the ratchet *f f*. This, at the hour, is attracted by the



electro-magnet E, allowing the ball to fall. J is a disc of brass equal in diameter to the upright *a* from the base of the ball to the floor Q. K I L is a piece of brass terminating at L in a square ring going round the support and fixed at K as a pivot. The whole disc is actuated by clockwork (not shown) to move in the direction of the arrows, and kept in its place by the ratchet G, which is kept pressed against it by the spring P, until acted on by the electro-magnet D at five minutes to the hour, when being attracted the disc is released, and, travelling round, raises the ball by means of K I L to the top; there the ball is kept by spring R pressing the ratchet outwards. Guides for the ratchets, &c., are not shown. The wires are connected up as shown to the battery B and clock M. The spring R must be only just strong enough to keep the ratchet in place, and the contact to raise the ball very finely adjusted in order that the electro-magnet D may be demagnetised in time to allow the ratchet G to catch the disc directly it has revolved once. If I have not succeeded in making my plan clear, I shall be pleased to afford further information.—S. HENRY SMITH.

[60316.]—**Electric Time Ball.**—Having been engaged constructing such an instrument for display in my own window, but had to lay it aside for some time owing to press of other business, and having seen the above query some two months ago, I became interested in what would follow; but, unfortunately, nothing of a practical nature has made its appearance. I could no longer resist the earnest appeals that have been made; consequently, I have sent rough sketch, and the following explanations of my design for the consideration of "Original Querist," so that by comparing notes he may be able to attain his long-wished-for desire. I raise my ball by means of a train of wheels, set in motion and stopped by a current of electricity, two minutes before every hour. C is the front plate of my regulator, with the two minute wheels and two levers: one lever is used to raise the ball, the other to let it fall; A is a box with three pieces of hammer brass fixed as shown. When the ball is in its normal position the long spring from the top of the box is in contact with the upper one of the two short springs; but when the ball is raised the long spring is pushed into contact with the lower short one, thus changing the current from electro-magnet *x* to electro-magnet *o*. The dotted lines show position of lever during the 58 minutes



of the hour. Suppose at two minutes to the hour lever No. 2 is in contact with pin on wheel (No. 1), a current passes in direction of arrows from battery to clock and lever (No. 1) to electro-magnet (*x*) attracting the armature (*d*), releasing the pin (*p*), allowing the wheel to turn as indicated, and raise the lever (L), the end of which is attached to the ball above, until it snaps into a catch on the armature of electro-magnet (O); attached to this lever is an arm (*e*), which presses upon the button of swivel, and charges the current from E M (*x*) to E M (*o*), releasing the armature (*d*), which resumes its original position in time to stop the wheel on the arrival of pin P; the whole remaining in this position for two minutes until at the hour, lever (No. 2) is in contact with wheel (No. 2), thus completing the current through electro-magnet (*o*) and dropping the ball. I use an insulated arrangement, so that the levers fall on to minute wheel pins exactly at the time required. The levers themselves are also insulated from the clock. The whole arrangement is placed underneath the window; the train is actuated by a weight. I trust I have made matters sufficiently clear to enable my brother in trade to proceed at once to finish his undertaking.—NORTHERN COUNTIES.

[60334.]—**Falling Bodies.**—"Vulcan's" seems to me the nearest answer to this question; but in a case like this, would it not save both time and space for some mathematician such as "F.R.A.S.," as "Vulcan" says, to send a reply? The question is interesting, to say the least. I still hold my opinion as to the earth behind retarding the stone. I did not say the body was retarded by the "spherical shell" (part of which is in front of it), but by that part behind it. Practically, "R. E. F.'s" statement admits this, although given as a flat contradiction. The earth is supposed homogeneous in this question, I understood. I quite agree with "R. E. F.'s" suggestion that "corrections" should be well founded.—M. YORK.

[60334.]—**Falling Bodies.**—Will "Dublieniensis" kindly give his authority for the statement he makes to-day, that "Every ellipse, no matter what its ellipticity, and no matter what its magnitude, described by a body round a centre of force, the force varying directly as the distance, will be described in the same time," as I should like to consult the work on astrological matters? Also, will "R. E. F." support me in stating that gravity is greater at the Equator than at the Poles, because a pendulum gains at the north and south of the equator on one thereupon? I suppose it will shortly be, as it appears it ought to be, a well-known fact that the slower a body falls, the greater is the attracting force. It cannot be too well known that "the force of gravity at the depth of a mile is far from being diminished, actually increased, so that a seconds pendulum at the mouth of a deep mine may gain several seconds a day on a similar pendulum at the bottom of the shaft." Many will be glad to learn that the faster a pendulum goes the less the force of gravity. Can particulars of this experiment be given? If a body is not retarded by the matter behind it, it amounts pretty much to the same thing, as the attraction ceases, and acceleration due to it, the matter in advance of it being diminished also. The proof afforded of the lack of homogeneity of the earth by the pendulum going more slowly at the bottom of a mine is indeed new. It is exactly what one would expect if the earth were homogeneous. Perhaps over deep soundings in the ocean the force is more at the bottom than at the surface, water being so much less dense than land. If this has been tried I shall be glad to hear the results; also if a pendulum has been found to go faster at the bottom of any mine. I have some recollection of reading the latter somewhere. A body passing through an unresisting earth might have its rates of acceleration varied by the varying densities of strata passed through, but would certainly not "be alternately accelerated and retarded," however the strata varied in density. I am under the impression that the average density of the earth has been ascertained for astronomical purposes, from observations, being about $5\frac{1}{2}$ times that of water, so that it would be very interesting to know of reliable data pointing otherwise. There is nothing in the action of gravity to compress any ordinary substance into extreme density, as towards the core of the earth the pressure would be slight; if earth is homogeneous the pressure should be greatest at surface, and if only $5\frac{1}{2}$ water is its density, the substances below ought to be pretty much of same density as on surface. Am not sure about the $5\frac{1}{2}$, but that is about the figure, I believe.—VULCAN.

[60428.]—**Silvering Glass.**—The original querist asked "where he could find an account" of the silvering process, and I gave exactly the information he desired. What *is* the matter, "Enquirer No. 2"? Why this savage onslaught? I am so sorry not to meet your views as to condescension; but even if our Editor were willing to fill a number or two, I do not feel it my duty to copy pages of other correspondents' letters to save you 2d. I was at some trouble to find the reference I gave, and no doubt you could obtain No. 794 for the above sum. I have no experience in this, or I would give it, with pleasure.—GLATTON.

[60432.]—**Architecture, &c.**—As the question of Protestant nationality has been put forth in regard to Gothic architecture, I may supplement my former reply by stating that Augustus Welby Pugin, the great originator of the present Gothic movement, has called Gothic architecture "Catholic architecture" in his "Ecclesiastical Architecture in England." As some people have considered the name "Gothic architecture" to be unsuitable, it may therefore be supplanted by the name "Catholic architecture," which is quite appropriate, both from historical connections and from its being the term adopted by its foremost reviver, whose dictum was, "Let us choose the glorious epoch before the Reformation as our type."—DELTA.

[60455.]—**Chemical.**—This query is not sufficiently explicit. Is the mark required to be "raised" in the ordinary meaning, or merely made? May the pencil be used wet—that is, dipped in water occasionally? Perhaps querist will answer these questions, and then he may obtain a more or less useful reply; but at present what he wants is rather too much of a puzzle, at all events for—NUN. DOR.

[60456.]—**Balm of Columbia.**—Impossible to answer this question without analysis. Perhaps it is a mixture of the tincture of cardamoms and of cantharides.—SAML. RAY.

[60458.]—**Old Oak.**—Unfortunately, the querist does not say what difference in shade has been produced; but a solution of permanganate of potash will produce a brownish tint, and a weak solution of iron a purplish black, both of which are modified by rubbing in linseed oil or wax.—NUN. DOR.

[60460.]—**Telegraph Circuit.**—It is not an easy matter to lessen the induction, and not easy to suggest a remedy in the absence of any knowledge of what "Amateur" would be permitted to do. He will find in back volumes a good deal on the question of induction, and may possibly, by diligent search, discover a remedy for the special case. Possibly, the best remedy is to put the speaking-circuit wires as far as may be from any others.—AN A.S.T.E.

[60464.]—**Coopering.**—There is no practical work on coopering, that I know of; but there is, in back volumes, information on the subject, and perhaps if the querist would ask definite questions he might receive replies, for there are plenty of readers, I am sure, who feel a pleasure in replying to queries, who would not undertake to instruct in the whole art of coopering.—BOOGE.

[60466.]—**Emery Wheel.**—Has this querist tried marine glue, or one of the waterproof cements which contain indiarubber? But why—oh why—does he not use a proper emery wheel? It is cheapest in the long run.—NUN. DOR.

[60470.]—**Malt.**—Is it permissible to ask this querist whether such a thing as he asks about has ever been done, or whether he wants someone to invent a new process for him?—NUN. DOR.

[60474.]—**Shirt Collar-Studs.** — The metal covers are stamped out near the size and are then "spun" on.—NUN. DOR.

[60475.] — **Gelatine Moulds for Plaster Casts.**—Has "Barium" tried the addition of a little bichromate of potash to the gelatine? Alum hardens the gelatine, but the bichromate, after the mould has been exposed to light, renders it insoluble. Let him omit the alum and add a little solution of bichromate.—NUN. DOR.

[60477.]—**Saccharin.** — "Sugar Baby" asks questions which are answered in the very pages he mentions. Of course, saccharin is soluble in water, as plainly intimated in pp. 500, 522, last volume, and no doubt any of the wholesale druggists would supply him.—F. I. C.

[60484.]—**Twilight.**—Although I cannot lay claim to be a first-class astronomer, I am sufficiently well acquainted with the elements of astronomy to know that the faintest stars visible to the naked eye are not rated fourteenth magnitude but the sixth. A reference to almost any book on astronomy would have saved "E. L. G." from falling into this error. He also ssys innocently that he has been in the same latitude without noticing any short twilights; but does he actually think that places of the same latitude have the same climate? For instance, Scotland and Labrador are in the same latitudes, yet what a difference in their climates! The following words of Dr. Robert Mann, F.R.A.S., F.M.S., may be of interest:—"It was at one time conceived that twilight lasted until the sun was 18° below the horizon, and then ceased. As a matter of fact, this is an altogether unsatisfactory and illusory conception. There is sometimes a very bright twilight long after the sun has reached this depression, and at other times there is absolute darkness considerably before. Alexander von Humboldt found that the duration of twilight was restricted to a very few minutes in the intertropical regions of South America. . . . By the astronomer's estimate, twilight is conceived to be at an end the instant a sixth magnitude star can be seen twinkling in the sky overhead." It will take a first-class astronomer to convince me that it is the appearance of a fourteenth magnitude star low down on the N. horizon that determines the limit of twilight.—R. E. F.

[60490.]—**Bookkeeping.**—Purely a matter of opinion. Every manager of a business keeps books in his own way, though there are certain general principles which can be found in any of the textbooks. T. Jones's "Bookkeeping," a complete treatise, at 12s., Simpkin Marshall, or any bookseller, will help him; but there are several lower-priced manuals.—SAML. RAY.

[60492.]—**Mechanical.**—In my answer to this, on page 137, there is an omission by the printer of the number 14 between 6 and 50 in the first line of the example.—LIBRA.

[60493.]—**Sewing Machine Cams.**—Surely this querist should give some idea of what sort of cams he means—"sewing-machine cams" is really too vague.—NUN. DOR.

[60498.]—**Induction Coil.**—One would need to see this coil before an answer could be given.—B. D.

[60500.]—**Coil.**—A street coil 9in. by 4in. would be a tremendous affair. Surely the correspondent knows that there is a large amount of "padding" in these appliances. It is bad economy to use cotton-covered wire in any coil. Look through indices for coils—medical and street.—NUN. DOR.

[60501.]—**Inks.**—I think "Nemo" can easily ascertain himself. The other ink is, I believe, made with logwood decoction and bichromate of potash.—J. T.

[60504.]—**Watch Jewelling.**—The stones are usually set in the holes by sinking them slightly below the surface of the plate and then burnishing the edges with, say, the point of a round broach. The stones with brass collars round them are for the top plate, the jewels being held in position by screws, the heads of which are partly sunk in the plate, and partly in the jewel-hole setting.—J. B.

[60505.]—**Salt and Lime in Water.**—If the lime is carbonate, it can be nearly all precipitated by the addition of lime cream to the water—stirring well; but the salt cannot be easily taken out. Querist should use purer water.—NAVAL ENGINEER.

[60514.] — **Silvertown Firing Battery.** — Having made these batteries up in large quantities, and used them while in the Torpedo Service of the Royal Engineers, I can give you full dimensions. Outer cell ebonite, two graphite plates fixed together by strips of lead at each end, from lead cap to lead cap; one zinc plate, same size as one carbon or graphite plate. Zinc plate is inserted into coarse flannel bag, and the sal-ammoniac packed round the plate; then tie bag round top close under lead cap; stand all three plates in outer cell, and pack round with carbon, &c., up to ½in. of top; cut four pieces of wood ½in. square, fit in top of cell to keep carbon, &c., in. Then seal with paraffin and pitch; the caps stand higher than top of cell.—J. SUTTON, late Royal Engineers.

[60540.]—**Tricycling Matters.**—Since writing my last letter in response to "Gamma Sigma's" query, I have thought of another reason why large level-geared wheels do not give such good results as small ones geared to the same height, and that is because the rider has to communicate his power through such a great distance to the rim, which means a loss, more or less, according to the size of the wheels; for instance, a pound pressure on the pedals would not represent a pound at the rim, so small wheels economise the rider's strength. What makes me think so is because small geared-up bicycles have not the same relative advantage over the ordinary bicycle, because the chain makes the distance about the same except up-hill, and that is easily explained by the rider not being thrown so far back, and therefore can keep over the pedals more. The Rover type is also faster over rough ground on account of the rider being placed between two wheels, not feeling the roughness so much. And both the Kangaroo and Rover type are better against the wind by reason of the low positions of the rider.—G. TOWNSHEND.

[60540.]—**Tricycling Matters.**—I cannot account for the superiority of small wheels geared up being more satisfactory to riders than large wheels geared equal, except it is the advantage gained by less windage—that is, assuming that it is a fact. "Gamma Sigma" has no need to look for any scientific matter from our present cycling press, as at present they, the various members of the staff, have nothing but racing on the brain. A few lines now and again as a slight change are devoted to blackballing any one in the trade who is honest enough to speak his mind. The stuffing-box to a certainty will take the place of the automatic. Now, by way of example of how the best ideas are treated by the cycle trade, some time ago (March 30th, 1885) I took out a provisional protection for the stuffing-box as applied to the steering handle of rack-and-pinion-steered machines. I submitted it to the trade, and they pooh-poohed it. If I had taken the full patent, I should now be able to have reserved a royalty on all the Crippers which will be steered by that means in the future. I think "G. S." could not have ridden a Cripper tricycle; otherwise his criticisms of the cross handle bar would have been very different, as the amount of support that can be obtained for the body when brought forward on the machine is one of the principal advantages; also, when needed, the pull upon the handles is very effective. There have been several machines through my hands with both handles to steer, which I could not sell. I should be most happy if "G. S." would give me a call and ride out with me. I will find a machine near to his idea, and he shall also alternately try the Cripper, when I think he will be convinced that the tricycle of the future is of the Cripper type.—C. LENI.

[60548.]—**Copper Boiler.**—Am sorry I overlooked this, but "Glatton" has supplied all you want. Taking sheet copper at 13 tons square inch and a factor of safety at 13—to allow for the riveted joint—will reduce it to 1 ton per inch sectional area, and as you have only $\frac{1}{16}$in. in the two sides, that will only allow 150lb. for the 7½in. diam., or 20lb. per square inch about.—T. C., Bristol.

[60548.]—**Copper Boiler.**—I am obliged to "Puzzled" for pointing out a mistake in my reply on page 178. The rule should be: Working pressure for *very* good brazing and properly-stayed ends $= 2{,}000\ \frac{t}{d}$; where t = thickness, and d = diameter in inches. This allows a working stress of 1,000lb. per square inch on the copper. Your pressure $= 2{,}000 \times \frac{\cdot 035}{7\cdot 5} = 9\cdot 31$lb. Test to 20lb. with cold-water pump.—GLATTON.

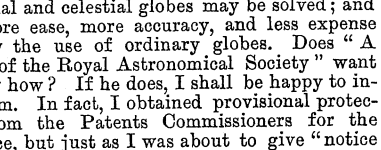
[60591.]—**Hardening Spring Steel.**—Carriage springs are hardened by heating them to a red heat and dipping into cold water. You must then draw it through the fire, at the same time pressing the end of a piece of chisel-rod till it flares off. You can harden small springs in the following way: Heat the spring to a red heat, dip it in cold water, now warm it sufficient to melt some tallow, hold it in a clear fire or gas flame till it flares off, and lay aside till cold. You will find this the right temper.—A. E. KEMP, Ramsgate.

[60591.] — **Tempering Springs.** — What is "Springee" trying to make poor fun of? Evidently of something he knows nothing of—that is, getting the temper of springs with a stick. My experience of getting the temper this way is confined to cart or carriage springs, and that goes back to 50 years. I have helped one of the best spring-makers I ever saw, and that was his way of tempering. I have seen plenty of others do, and have done it myself scores of times; and should I want to harden a spring to-morrow, I should do it that way. I am not entering into the different methods, only say it can be done and a good job made. The way is: after the plate is set, and made a dull cherry-red, dip in the water, then pass your plate back and forwards through your hollow fire; then take your bit of dry chisel-rod, and rub the end of it back and forward, and if hot enough, the end of the wood sparkles when the temper is low enough; in fact, you can almost tell by the feel when hot enough or getting near that way. The wood slips over as if the steel were greasy.—F. G. F.

[60619.]—**Cornwall.**—I think that the following should meet "T.'s" requirements. "Bibliotheca Cornubiensis," by Boase and Courtney, three vols., published by Longman and Co.; and Tregellas's "Cornish Worthies."—PENWITH.

[60622.]—**Astronomical.**—Suppose your celestial globe is of glass, and that you place your eye exactly at the South Pole, having first elevated the North Pole to the lat. of place. What you now see transferred on paper (as a picture) is a perfect planisphere. The wooden horizon appears an "oval" or ellipse; the stars in the south hemisphere seem farther from each other, being nearer to the eye, &c. The globe turning on its axis on the fixed wooden horizon will present exactly the same panorama of stars rising and setting as the said picture or projection turning on its centre against the upper disc or "aperture" of the planisphere, the representative of the wooden horizon (though in the latter it is the horizon that is made to revolve, but with exactly the same effect.) By the way, apropos of this, I may be permitted to add what I wrote for, but did not send to, the MECHANIC more than seven years ago, having reference to a reply which "F.R.A.S." made to my query (37811, Vol. XXIX. page 635). *Planispheres.*—Thanks to "A Fellow of the Royal Astronomical Society" for having so kindly replied to my query. But I must inform him that what he (and, indeed, other eminent men to whom I wrote) think "absolutely impossible," *ex necessitate*, is quite simple and feasible. In other words, a planisphere can be constructed by means of which all the problems (without exception) on terrestrial and celestial globes may be solved; and with more ease, more accuracy, and less expense than by the use of ordinary globes. Does "A Fellow of the Royal Astronomical Society" want to know how? If he does, I shall be happy to inform him. In fact, I obtained provisional protection from the Patents Commissioners for the appliance, but just as I was about to give "notice to proceed," I was informed by a respectable nautical instrument publisher, of London, that a retired Navy Schools Inspector had anticipated my ideas. I therefore desisted, as I placed the fullest reliance on the publisher's statement. He said that my model was almost identical with Mr. ——'s. "It works the problems in navigation, including latitudes, longitudes, azimuths, amplitudes, great circle sailing, &c."—in other words, every problem in spherical trigonometry. How wonderfully some important things are concealed while the world knows very often the most insignificant trivialities! Having invented this instrument, I applied to the most eminent astronomers in the three kingdoms, and not one of them knew of planispheres that solved every problem on globes, while some of them thought such an apparatus an impossibility. In azimuths and great-circle sailing especially, a problem of ten minutes' tedious calculation can be solved with this appliance by simple inspection only—no calculation required.—D.D., Youghal.

[60622.] — **Astronomical** — α **Arietis.**—As "F.R.A.S." has already replied to this query, I would only add that the reason why α Arietis was not entered in "Webb" or the "Star Guide" was owing to the distance of Smyth's *comes*. He gives a position angle of 107·3°, and a difference in R.A.



of 19·5°, which would make the purple 11-magnitude of which he speaks about 283″ distance. He says "The large star is followed by three small stars, forming a line across the parallel, of which the middle individual is B." I append a copy of his diagram. I am not aware that the actual distance has ever been measured. The annual proper motion

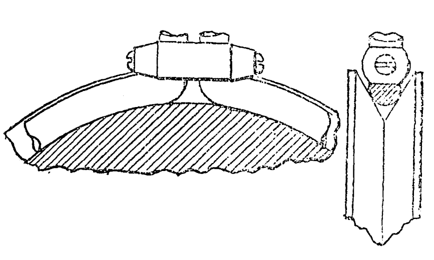
of α Arietis is about 0·246″ in 126°. Loomis, through some mistake, gives the distance of the *comes* at 30″. In Darly's "Astronomical Observer," the following passage occurs: "Mr. George Hunt *glimpsed* a minute star close in the rays of α, 15th January, 1864, 4in. aperture. A very close faint star, S. of α, was observed on the 4th January, 1864, with Mr. Younge's 9½in. aperture."—H. Sadler.

[60625.] — **Astronomical.** — Errata. — Two errors occur in my reply. The first is mine, the second the printer's. Line 42, for "about five times the sun's own apparent diameter," read "about ten times, the a. d. being sometimes a little more, sometimes a little less, than half a degree." Last line, for "the old man in the new moon's arms" (fie Luna!) read "the old moon in the new moon's arms."—George Bell.

[60646.]—**Cracked Gongs.**—I had a hand bell which was cracked. Solder was sweated into the crack, which quite restored the sound; but in a month it gave way again. A small patch of thin brass was then soldered over edge of crack inside the bell, and it has stood well, and sounds exactly as it did before being cracked. The bell is about 3½ to 4in. diameter; the crack about ⅜in. up, and the patch about ½in. square.—T. F. S. T.

[60654.]—**Locomotives.**—I can only answer part of this query. (1) M.R. engines: 1292, 1299, 1286, 1301 all belong to the 1282—1311 class. Dübs and Co., 1876. Coupled wheels 6ft. 6in., and cyls. 17½ × 26. Illustrated in the "E. M.," Vol. XXX. page 69. 109 to Class 101—110, by M.R. Co., 1877, 6ft. 6in., cyls. 17½ × 26. 1377 to Class 1377—1406, 6 coupled tank shunting engines by M.R., 1878. 169 to Class 165—169, M.R., 1870, and rebuilt at various dates, 4-coupled, 6ft. 8in., cyls. 18 × 24. (3) S.E.R. No. 159 (Class 150—160) 4-coupled, 6ft., with leading bogie, 3ft. 6in. wheels, cyls. 18 × 26, diameter of boiler 4ft. 4in. (4) G.N.R. No. 229 (Class 229—240), 7ft. single, cyls. 17 × 24.—A. J. H.

[60669.]—**Gut Driving Bands.**—Cut your gut to right length. Slightly taper both ends (by cutting) to enter hook and eye easily. Nip your gut in vice lengthways and screw on fastenings. If hook comes off, before putting it on again run a pointed tool round the whole inside thread to clear it out; otherwise the thread will not bite on the gut. I have discarded gut bands with their annoying fastenings, and have used for the last two years (with entire satisfaction) a fastening (of which I send sketch) together with stout plaited



sash-line or leather bands. Ordinary rope and gut do not answer quite so well, as they are liable to untwist. This fastening stands the utmost strain the lathe will bear, and is attached in a moment. For sawing heavy cuts and any purpose requiring a reliable tight band, it is admirably suited.—Hendon.

[60700.]—**To Draughtsmen, &c.**—I am greatly obliged to "E. L. G." for his interesting and instructive reply, and if it would not be troubling him too much, I would like further information. Would you give me a description and sketch of the instrument you name, the old-fashioned sector for the division of straight lines and circles, with its scale of polygon sides, and if it be the most royal road, why suggest the beam compass? I ask this last in no hole-picking spirit, but for information. Also, please describe the working of the lazy-tongs, with their construction, as I am not clear on that. And if any other correspondent is acquainted with other instruments for these purposes a description would doubtless be interesting to very many readers besides myself, as I think an instrument for these purposes ought to be in every workshop —a thought born of my own experience. In the shop where I presently work there are, besides myself, four men, including the foreman, any of whom, having a circle to divide, just step round first time with some random chord, and gradually get nearer each trial-stepping—a time-devouring process; and yet these men are, I believe, not below the average for mechanics in middle life as to education. As for myself, until recently I calculated the chords by trigonometry, but being a dabbler in inventing, I have invented an instrument for these purposes. This is my reason for asking all this, as, being correctly described by my *nom de plume*, the cost of a patent is to me a very considerable sum, so am feeling my way before proceeding.—Workman.

[60726.]—**Cement.**—Yes. Indiarubber would do, only it won't dissolve in spirits of wine. The solvents commonly used are naphtha, benzol, chloroform, and bisulphide of carbon.—Paul Ward.

[60728.]—**Steel and Iron Tubes.**—My reply to this in last week is mixed up. What I wrote was 90 × 12 = 1,080lb., say ½ ton, which would require ¼in. sectional area, that is ⅛in. plate.—T. C., Bristol.

[60737.]—**Mathematical.**—There is no simple general solution.

$$\left.\begin{aligned} x^3 - y^3 &= a \\ x + y &= b \end{aligned}\right\} \quad \ldots\ldots\ldots\ldots\ldots\ldots \quad (1)$$

Let— $x - y = u$

Then— $x^2 - 2\,xy + y^2 = u^2$

and— $x^2 + 2\,xy + y^2 = b^2$

$\therefore\ 4\,xy = b^2 - u^2$

and— $2\,(x^2 + y^2) = u^2 + b^2.$

Factorising (1) we get—

$$u\left(\frac{u^2 + b^2}{2} + \frac{b^2 - u^2}{4}\right) = a$$

i.e.— $u(u^2 + 3\,b^2) = 4a$; or— $u^3 + 3\,b^2\,u = 4a.$

Let— $u = p + q$

adopting Cardan's sol. of cubic, then—

$$p^3 + q^3 + 3\,pq\,\overline{p + q} + 3\,b^2\,\overline{p + q} = 4a$$

and let the remaining condition between p and q be—

$$3\,pq + 3\,b^2 = o;\ \text{or—}\quad pq = -\,b^2$$

the equation becomes—

$$p^3 - \frac{b^6}{p^3} = 4a$$

or— $p^6 - 4ap^3 - b^6 = o$

$p^3 = 2a \pm \sqrt{4a^2 \times b^6}$

so— $q^3 = 2a \mp \sqrt{4a^2 \times b^6}$

$$\left.\begin{aligned} p &= \sqrt[3]{2a + \sqrt{4a^2 + b^6}} \\ q &= \sqrt[3]{2a - \sqrt{4a^2 + b^6}} \end{aligned}\right\} \text{or } w\,.\,\sqrt[3]{\ \text{do.}} \left.\begin{aligned} & \\ & \end{aligned}\right\} \text{or } w^2\sqrt{\ \text{do.}}$$

$$\text{or } w^2\,.\,\sqrt{\ \text{do.}} \qquad \text{or } w\sqrt{\ \text{do.}}$$

w, w^2 being the cube roots of 1

$$\begin{aligned} 2\,x &= b + u = b \times p \times q \\ 2\,y &= b - u = b - p - q \end{aligned}$$

hence x and y, by putting above values of p and q. —No Sig.

[60743.]—**Cast-Iron Piston Rings.**—I have made several piston-packings this way. I turn them the diam. of piston and cut them; I cut a piece out if not tight enough, and lay a piece of brass is to stop passage of steam.—B. Helme.

[60743.]—**Cast-iron Piston Rings.**—If the piston block is in halves, or, more properly speaking, has a cover on, you will find bolts or other means of fastening them together; if not, you will have to carefully spring them on, most probably the latter, as the springs are only narrow. When I draw rings of this description, I get a tool like a hammer, but with one end in the shape of an axe, but very dull, so as not to cut the metal. Lay the spring on an anvil, or something very solid, and carefully hammer inside, taking care that the slight indent the tool makes goes square and even across the spring, or it twists; taking care that the spring is solid every blow you give, or it will snap. Keep trying it very gently until you hear that it is solid, then hammer round; but I may say that rings when hammered never fit as well again, be they ever so well done. Could you not get some steel ones, as they are safer?—A. O. H.

[60744.]—**Question in Dynamics.**—E. Conry should be more cautious: he has stepped into "Humbugged's" trap. The monkey cannot "begin to run up the string with velocity," not even if he goes to work "gently and regularly," as E. C. modestly requires. He could only raise himself by exerting a pull on the rope greater than that of his dead weight; but as m cannot meet that pull, being only just heavy enough to balance his dead weight, motion must ensue—that is, on the least contraction of the monkey's muscles in the effort to rise, up goes m and down goes the monkey as far as the rope will allow. The motion is not accelerated —here again E. C. is wrong—for after it is once started no unbalanced force is acting on either body. What can he mean by "accelerating through momentum"?—W. A. S.

[60744.]—**Question in Dynamics.**—I see a reply to this query in the last number of the "E. M." (October 22nd), which I do not think is correct when tested by the laws of dynamics. A string passes over a pulley, having a monkey at one end and a weight at the other, the mass or weight of each being the same. Suppose the monkey to be strong enough to raise its own weight 8ft. in a second, or 2ft. in a quarter of a second, and suppose for the present that the ascent is made by a series of bounds each 2ft. high; now, at the first bound the monkey would use a force which would raise his body or m 2ft. in a second, and the reaction of this force would tend to lower the end of the rope from which he starts with the same force; therefore the end of the rope would be lowered with the same force and velocity as the monkey raises his body, or, which is the same thing, the weight at the other end of the rope would be raised with the same velocity, so that at the first bound the monkey and opposite weight will both be raised a certain distance. Now the monkey can only raise m 2ft. in a quarter of a second; hence, as the weight raised in the first bound is 2 m, the height to which it and the monkey is raised is 1ft. Now it is easy to suppose the bounds that the monkey makes to be reduced in length, although the time of ascent will be the same, and finally, when these are sufficiently reduced, we get a continuous motion. The result will be that the weight will rise as fast as the monkey, and both will rise at a speed of 4ft. in a second, just half of what the monkey could do if the rope were fixed.—M.I.C.E., Bath.

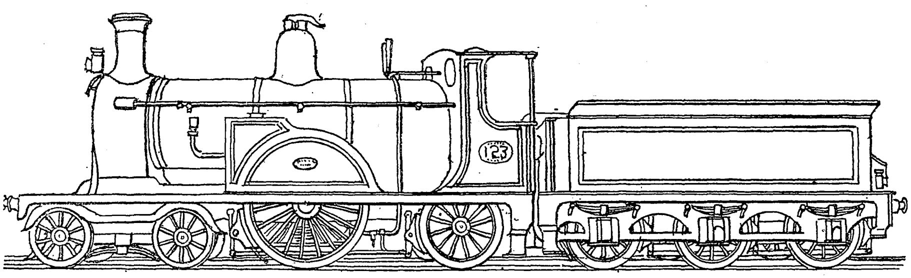
[60748.]—**Electricity at the Science and Art Exams.**—Kindly read replies 60557 in last week's English Mechanic, as also in the week before. To these I can only add: Read carefully Silvanus P. Thompson's "Electricity and Magnetism," also Sprague's "Electricity." Join, if possible, one of the science and art classes in your neighbourhood. If you cannot, then read a chapter, and repeat every experiment therein described until you have a practical knowledge of the subject. Write for the questions given for the last ten years to the secretary of the Science and Art Department, S.K. When you have them, try to answer every one, a few at a time, and check your answers with your books. If you go in for "honours," you stand a fair chance of getting ploughed if you do not know mathematics; but arithmetic will carry you through the "advanced." —S. Bottone.

[60748.]—**Electricity at the Science and Art Exams.**—To pass the advanced stage you will need a good all-round acquaintance with the facts of electrical science, and to obtain this requires some genuine study. The best thing to do is to attend a class conducted by a really good man. If you cannot attend a class, study two or three new books, and make careful notes as you go along. Silvanus Thompson's book is very good; you cannot do better than obtain it for one. I would especially recommend you to work out the examples he gives at the end, a lot of exact information being acquired in that way relative to measurements, &c., which would otherwise be missed by merely reading the work. Many of these questions, too, are a fair sample of what you will have at the exam., so that you cannot do better than work up at leisure the information necessary to answer them. As for other text-books, those of Sprague and Fleeming Jenkin may be mentioned, though I have not seen the former. In any case, you ought to have more than one, because different authors put the same thing in different lights—hence, a point not very plainly elucidated by one becomes perfectly clear to the comprehension when a second is consulted. It is hardly needful to observe that you should seize every chance that may offer itself of seeing and examining the costlier kind of electrical apparatus. This is by no means absolutely necessary, but it will be a help. If you intend going up for the exam. as a private student and not as member of a class, it will be requisite to apply for a paper to the local secretary of the district where you reside about the end of March, and pay, if I remember rightly, the sum of 2s. In addition to obtaining a paper, the secretary will also, in due course, advise you when and where the exam. will take place. With respect to mathematical knowledge—no, you will not need much. Silvanus Thompson's book gives nearly all necessary. Is the exam. a stiff one? Well, tolerably, but nothing whatever to be afraid of. It would be worthless if *very* easy. This year 1,627 persons submitted themselves in the advanced section, of whom 182 secured first classes, 752 second classes, and 693 failed. In the honours section not a single individual passed in the first class, and there were only seven seconds—and this for the United Kingdom. What are our electrical students doing? —First-Class Advanced.

[60753.]—**Light.**—To W. G. Penny.—Mr. M. York, M.I.C.E., seems to think that, to say that a ray falls obliquely upon a surface is to imply that the surface is flat.—W. G. P.

[60762.] — **Engine Flywheel.**—This seems about right for the engine, but as regards the engine you do not give the steam-pressure, so cannot give H.P. You would require a good pressure to drive the saw as it should be driven. Have a long strap, say 15ft. centres.—T. C., Bristol.

[60747.]—**New Caledonian Single Engines.** —I made a sketch of No. 123 at Edinburgh and send herewith. It appears this is not entirely novel in design, as Mr. Park has employed the same arrangement—i.e., inside cylinders, single driving wheels, and leading bogie, in engines on the Great Northern of Ireland since beginning of 1885. The Caledonian engine looks very well in its dark blue



colour, with its silvery-looking mountings and pickings. As the dimensions have already been given, it is useless to repeat them.—B.

[60765.]—**Area of Sewer.**—The area of a sewer 2ft. diameter is 2 × 2 × ·7854 = 3·1416. Now ascertain by proportion what must be the area of the sewers for 10,000 and 15,000, and then find their diameters by dividing the areas by ·7854 and taking the square roots. They are 2ft. 9in. nearly and 3ft. 4in. nearly respectively.—LIBRA.

[60765.]—**Area of Sewer.**—As you say 2ft. diam. for 5,500, I assume you mean circular in section. Of course there are other sections; 2ft. diam. = 4 circular feet, therefore 10,000 would require $\frac{10,000}{5,000} \times 4 = 7{\cdot}3$ circular feet, or a diameter of 2ft. 8½in. For 15,000, area would be 11 circular feet., or a diameter 3ft. 4in.—T. C., Bristol.

[60765.]—**Area of Sewer.**—For 10,000 the diameter would be—

$$\sqrt{\frac{10,000}{5,500}} \times 2 = \frac{10}{7{\cdot}4} \times 2 = 2{\cdot}7\text{ft.}$$

For 15,000 the diameter would be—

$$\sqrt{\frac{15,000}{5,000}} \times 2 = \frac{5{\cdot}5}{3{\cdot}3} = 3{\cdot}3\text{ft.}$$

—A. E. F. Manchester.

[60765.]—**Area of Sewer.**—This question can be worked by simple proportion if we put the area of cross section of sewer instead of the diameter, the reason being that the area of a circle of radius 2 is not twice but four times that of a circle with radius 1. The area of a circle 2ft. diameter being π feet, we have—

$$5{,}500 : \pi :: 10{,}000 : 5{\cdot}7119$$
$$5{\cdot}500 : \pi :: 15{,}000 : 8{\cdot}5679$$

We have now to find what diameters correspond to areas of 5·7119 and 8·5679 sq. feet respectively; this we may do from the formula—

$$d = \sqrt{\left(\frac{4a}{\pi}\right)};$$

the diameter of the sewer being, for 10,000 people, 2·697ft., and for 15,000 people, 3·303ft. This may not be the shortest way, but it is the simplest to follow.—R. E. F.

[60767.]—**Exploding Gas by Electricity.**—As you intend to use a Bunsen cell for exploding the gas, it would be better to explode it by means of a short length of very fine platinum wire, which would become heated sufficiently on closing the circuit to explode the gas. Glass tubes let into the cylinder would be the best insulators.—A. E. F., Manchester.

[60767.]—**Exploding Gas by Electricity.**—The spark from a Bunsen cell might explode gas in a cylinder, but there would be greater chance of success if the Bunsen were connected to a small induction coil. Guttapercha will do for insulation where the wires pass through the side of the cylinder, the "terminals" being simply a small part of the wire stripped of its insulation.—BOBADIL.

[60767.]—**Exploding Gas by Electricity.**—(1) An ordinary Bunsen will do; but it is not the most convenient form by any means, and for intermittent work is about the most clumsy and costly you could get; moreover, the E.M.F. of one cell is so low that you would not, without the aid of an induction coil, get it to spark across the smallest space without actually touching the wires together and then parting, and even then the spark would be so small that I should doubt its power to explode any charge of gas. (2) Guttapercha or a small bone ring filled up with melted indiarubber. (3) Platinum.—E. CONRY.

[60767.]—**Exploding Gas by Electricity.**—"Volta" will hardly find a Bunsen cell sufficient to explode the gas; it would be necessary to use an induction coil. If the cylinder is made of glass, it would only be necessary to fuse the wire in, and that would be sufficiently insulated, glass being, as "Volta" knows, a non-conductor. The terminals ought to be made of platinum; if the diameter of the cylinder is not very great, "Volta" will find no great difficulty in fixing the wire. How far the points are apart must be decided by the length of spark you have at command.—V. B.

[60770.]—**Field-Magnet Winding.**—TO MR. BOTTONE.—I do not think you will do much with your machine, as the shape of the armature is bad. However, before discarding it, put about 20lb. of No. 16d.c.c. on each limb of the F.M.'s, and couple all four up in series. This will probably give you enough to light 12 five candle-power lamps.—S. BOTTONE.

[60771.]—**Ventilation.**—For ground floor, put an air-shaft each side of fire-flue, and carry them up to same level. Put a Sheringham or mica flap ventilator in both ground and first floors (near ceiling) into the right and left hand air-shafts. Tobin tubes should now be placed as far as possible from fireplace. The area of each shaft should be about 60 square inches, and tubes about 30 square inches. In hall, I would suggest two circular or rectangular adjustable gratings at floor level, and in ceiling at top of staircase a wire gauze, connected by means of a tube to louvre ventilator on roof. For attics, adopt same method, and have gauze over gas jets if possible in both cases. A gill stove in hall would be useful. If you go "twisting or prolonging" your hot-water service you will perhaps have to pull down half your house to get at them when repairs are needed. —S. M. S.

[60771.]—**Ventilation.**—I should recommend "A. A." to have a central shaft in the centre of chimney stack, and let it be the next to the kitchen flue, that always being warm, and connect each room to air-shaft with opening as near the ceiling as possible, and have an Arnott ventilator, either with cloth or mica flap. Sheringham ventilators are for the ingress of air, not for egress, which Arnott's are. A Sheringham may be put in the wall connecting with the outer air, which can be admitted at will, or Tobin's tubes in two corners of the room; also, at least, a 3in. or 4in. pipe under floor to a ventilator in the hearth that would only want to be opened when the fire is being used. This arrangement will ventilate his rooms very fairly, and ordinary register stoves can be used; the air-shaft would want to be carried up 3ft. or 4ft. above chimney pots.—F. G. F.

[60771.]—**Ventilation.**—The following method is suggested:—1. In Cold Weather.—Inlets: Opening below gill stove in hall; admit air to rooms by opening over lintel of doors. Outlets: Opening in ceiling flowers over chandelier, passing into chimney. 2. Warm Weather.—Inlets: Sash windows, with sash blocked open 3 or 4in.; or openings in walls 6ft. high, fitted internally with some form of diffuser. Outlets: Tube opening near ceiling, passing into shaft running up near kitchen chimney. Warm by slow combustion grates, fitted with air chamber on Galton's plan (this makes an additional inlet to each room). Calculate inlets on basis of each inch, admitting 125ft. per hour. Arrange to change air three times per hour; 24ft. of gas (equal 80 candles) is excessive for a moderate-sized room, if properly burnt. —MEDICUS.

[60771.]—**Ventilation.**—In building my own house I made all the flues in duplicate to each room as A. Alabaster intends to do. These double flues are uncertain in their behaviour, owing to the fact that fresh-air inlets are not sufficient, and therefore the flue with the weakest draught sometimes reverses its current. I made fresh-air inlets in different forms and positions in different rooms, and they all had to be closed for the simple and all-sufficient reason that we neither have nor can have a warming apparatus in the house competent to deal with the enormous volume of air passing up the flues, which in the whole house is probably not less than 2,000 to 4,000 cubic feet per minute. A heating apparatus capable of raising this volume of air, say, 10° Fahr., and at the same time keeping it perfectly fresh and sweet, is anything but a simple matter; we tried two in succession, but both failed after a time. When fresh air is allowed to leak in at all crevices it is so distributed as to be only a limited nuisance, and this way, which has been followed by house builders from time immemorial, is, perhaps, the safest for A. Alabaster to adopt if he does not want to spend a fortune in experimenting and failures. In my own case, the matter was seriously considered before we commenced to build, a special room was set apart for an air-warming apparatus, horizontal flues were built in the walls to supply air to the rooms, double flues to every room terminating as chimneys above the roof, and the result is a thorough and complete failure. I cannot advise A. Alabaster to go and do likewise.—998.

[60771.]—**Ventilation.**—It is one of the absurdities of architects to think about outlets for foul air, and leave the inlet to chance. The result is, of course, draughts—then sand-bags to windows, draught preventers to doors, resulting in smoky chimneys. They also put the outlets near the ceiling to carry off the warmed air, with the result of giving the inmates a cold stratum of air about their legs, and a half-poisoned air to breathe. Now, the real secret of good ventilation is the very reverse of all this. Provide adequate inlet, and in all probability the fireplace will amply control the supply. Let the fresh cool air enter at the ceiling, and it will sweep the foul air away to the chimney, and give good air to breathe and an equal temperature at the head and the feet. A thermometer will often show a difference of 10° or 15° between these in ordinary rooms. The best of all modes of ventilation is to make an opening in the wall, preferably just over the door and into a passage. I take out two bricks for the purpose, and then cut away above them on each side, so as to have a good slope; I then make a wood casing, sloping a little below the opening up to within 6in. or 7in. of the ceiling, where it forms an opening 3in. wide. The air, as it is drawn in strikes the ceiling, and spreads out in a sheet, which then begins to descend, and tends towards the fireplace, thus giving a free inlet. The casing is covered by hanging a picture over it, and one can be adjusted in the passage so as to conceal the opening without interfering with the inlet of air. I fit up every room in my house in this way, so that the bedrooms are always fresh and pleasant. Of course, it would be an improvement to use in sitting-rooms the new gas-burners, which can be provided with a separate outlet for the products of combustion into the chimney, and prevent them from mixing with the air of the room.—SIGMA.

[60771.]—**Ventilation.**—In reply to Arthur Alabaster, I would advise him not to use Sheringham's ventilators as inlets from the outer air, and not to use special air-flues running up to the stack with the smoke flue. Such air-flues are apt to act as inlets, unless there is an ample supply of air from other openings, and when they do, smoke will sometimes leak from the smoke-flue into the air-flue, and thence into the room. If the smoke-flue is lined with a 9in. pipe, it will serve both for smoke and air perfectly well. Carry a zinc pipe, 5in. square, from the centre of the ceiling into the flue. Provide a wire grating in the pipe, and a silk valve against it to prevent any back draught. Let the pipe open through the ceiling covered with any kind of ornamental device desired. A solid plaster boss, about 12in. diameter, with a space of 2in. between it and the ceiling through which the air can pass freely from all sides, answers perfectly. Use grates in the room of the kind supplied by the Coalbrookdale Company for controlled combustion. Over the door have openings about 3in. deep and 18in. long, to allow air to come in freely from the passage or hall. These openings can be covered with any ornament desired. In the hall have a gill stove, or other warming apparatus, and an opening from the outer air equal in area to all the flues in the house, to supply fresh air. No Tobin tubes will be then required. Arrange this inlet in such a way, if possible, that the wind will not affect the current of air into it. A shaft from the top of the house, open freely to the air above, is the best way to secure this, but rather expensive. If not arranged thus, a valve must be provided to regulate the ingress of air. Do not overlook the fact that when ventilation of the rooms is arranged thus: the warmest air in the room, that near the ceiling, is constantly being removed, and that a corresponding amount of heat must be supplied to keep the rooms warm enough. On the other hand, the warmest air is also the foulest, and the air you specially want to get rid of. The stove in the hall should be equal in heating power to at least 120ft. of 4in. hot-water pipe. —A. G.

[60772.] — **Running Lathe Backwards.** — Drill a hole into mandrel and chuck; cut a thread in mandrel, and fit a screw that will enter chuck. I have one that has been in use for years.—OLD NOVICE.

[60772.]—**Running Lathe Backwards.**—Why use a chuck for the grindstone? Have a slightly conical hole in nose of mandrel, and turn end of grindstone spindle taper to fit. This will drive the stone, or even a drill, either way.—T. C., Bristol.

[60772.]—**Running Lathe Backwards.**—As you use your lathe for grindstone, you cannot damage it much more by boring a hole right

through the driving chuck and mandrel nose. When the former is screwed on the latter, taper the hole slightly and insert a pin, which will effectually stop the chuck from working loose. You can also put a set-screw in your driving chuck and drill a small hole on your mandrel nose for the point of the screw. If your lathe is of any value, never use a grindstone on it.—DYNAMITE.

[60773.]—**Legal Query.**—"Optotypi" would run a great risk in practising and calling himself an oculist without qualification and registration. By the Medical Act, 1858, persons practising in medicine or surgery must be duly *qualified*, and their names registered according to the Act. "Optotypi" must know that, although an oculist is a specialist, he can do nothing that is not included in "practising in medicine or surgery." Besides the risk of prosecution and a fine of £20, he runs a still greater risk of any dissatisfied patient getting a big sum in damages for maltreatment. This would be on the ground of non-qualification, even although "Optotypi" had treated the case quite as well as any regular practitioner would have done.—B.SC. (and Solicitor), Plymouth.

[60775.]—**French Wire or Sheet Gauge.**—The numbers 0000, 000, 00, and 0 do not belong to the French decimal gauge, the thickest wire being No. 20 and the thinnest No. P. Perhaps you mean the Birmingham wire gauge or the American wire gauge, both of which contain the numbers mentioned. Below are the sizes of the French gauge, with nearest British standard gauge numbers:—

—W. PATON, Weaste, Manchester.

[60776.]—**Boiler.**—This is small for a 6-horse nominal; it would, perhaps, with a good draught, give 6 H.P. actual. The flue should extend up the sides to, say, half the diameter of boiler. There is no occasion to have a straight flue and side return flues, but have it as indicated above.—T. C., Bristol.

[60776.]—**Boiler.**—"Willing to Learn" will find a plain cylinder boiler 12ft. by 3ft. will supply his 6H.P. engine if properly set, and if he cuts off at about two-thirds of the stroke. The boiler must be carried on angle plates, the fire bars must be 3ft. wide and 2ft. long, and not more than 12in. clear between top of bars and bottom of centre of boiler. A single flue the shape and width of the lower half of the boiler, and as shallow as possible, will be required; our own flue is the shape of the lower half of the boiler, and only 5in. deep. What is considered as the bridge in an ordinary boiler setting is continued in ours the whole length of the boiler to keep the flame, and heat up to its work. At the end of the boiler should be placed the water tank for feeding, the flue surrounding this after it leaves the boiler. Our own boiler is a simple cylinder, 3ft. 6in. in diameter, 15ft. long, and using ordinary gas coke as a fuel, drives a 12H.P. engine easily. If "W. to L." lives in Lancashire, it may, perhaps, be worth his while to see our boiler setting and arrangements. The Editor of the "E.M." knows my address.—998.

[60778.]—**To Mr. Bottone.**—You must either use more of your cells coupled up in series, or else, if you do not care to run the lamps for more than three hours at a stretch, you can use two or three cells of the chromic acid battery described and figured by me about six weeks ago.—S. BOTTONE.

[60779.]—**Clark's Gas-Lighter.**—The battery is a chloride of silver one, solution salammoniac. If you are not a mechanician, take it to a philosophical instrument maker. It used to be the practice, a year or so back, to unscrew the bottom (battery) half of the instrument, and take it to the shop where the lighter was bought, and receive a fresh battery in exchange by paying a shilling or two.—PAUL WARD.

[60779.]—**Electric Gas-Lighter.**—Clarke's first patent was a small circular battery of the sort known as Clarke's or Delarue's chloride of silver cell, working an induction coil. His second was a most ingenious adaptation of the Wimshurst or Voss statical induction machines, being a little glass cylinder on a spindle revolving within another similar cylinder, with brushes of loose wires hanging down and touching the glass, to act as collectors. The spin was given to the cylinder by a small train of cogwheels put in motion by the pressure of the thumb upon a button which projected through the side of a vulcanite cylinder containing the whole. You can renew the battery by unsealing, scraping the used-up chloride of silver off the silver plate, replacing it by fresh chloride generally about $\frac{1}{8}$in. thick, covering that with thin white flannel, which probably you will find already there, and which should be washed first (blotting-paper is also used), moistening the whole thoroughly with salammoniac and water, saturated solution, rolling the whole again round the central wooden cylinder, replacing it within the zinc cylinder, re-marking connections and sealing up again within outer case.—E. CONRY.

[60780.]—**Wimshurst Electric Machine.**—"Electric" cannot do better than obtain the ENGLISH MECHANIC of the 6th November, 1885, and then read the "Few Practical Hints upon the Working of the Influence Machine." He there will see the cure for almost all the points which can possibly arise.—J. W.

[60781.]—**Corundum for Aluminium.**—It depends entirely on the method you intend to adopt in the manufacture, whether the corundum of the composition given would be suitable.—A. E. F., Chemist, Manchester.

[60783.]—**Battery Power.**—Seven cells of the size named will be required to light the 8 12-volt lamps, but you would get a better light with eight cells. The lamps should be in parallel. I do not think the battery would give the current required—viz., about eight ampères—for more than three hours.—W. A. W.

[60783.]—**Battery Power.**—Your particular lamps, if tolerably economical, will require a current of 16 ampères, and your 12in. by 16in. double-carbon battery should easily furnish this current. The number of cells you will requre will be six or seven, coupled in series according as to how correctly the lamps have been labelled as to voltage. Run your lamps in parallel. If you use double the number of cells coupled, two in multiple and 6—7 in series, you will, of course, get light for double the time.—PAUL WARD.

[60783.]—**Battery Power.**—Depends entirely how you intend to couple your lamps. If in series, then $8 \times 12 = 96$ ohms. Now a well-made bichromate cell gives about 1·85 volt. As about 1 ampère is needed in each lamp, you would require about 50 cells in series to do the work. Supposing that you couple up in parallel, then 12) 8 (1·5, about $1\frac{1}{2}$ ohm. resistance in the entire circuit. But as each lamp requires about 1 ampère to light it, so you would want at least 8 ampères. To get these 8 ampères through an external resistance of 1·5 ohm, along with, say, ·08 ohm internal resistance of the battery, equal to, say, about 1·6, you would want (to be on the safe side) about 16 cells, coupled up in series.—S. BOTTONE.

[60785.]—**Induction Coil.**—If well made, it will give 1in. spark, under the given conditions. Shall be happy to reply to any query you may desire to ask.—S. BOTTONE, Stanley-road, Carshalton.

[60785.]—**Induction Coil.**—Six Bunsens connected to Dyer's coil are about equal to the battery power Dyer himself recommends—viz., six Groves. With the latter the spark obtained is about 1in. long.—BOBADIL.

[60786.]—**Colouring Photographs.**—This can be done in either water or oil. For oil, mount in the usual manner on stiff millboard; then coat over with a warm solution of gelatine; paint with the common tube colours, using, however, only the transparent and semi-transparent ones. For water-colour, take the mounted photo and brush it over with a solution of ox-gall in water until the moisture lies evenly all over, or, what is better, lick the photo with the tongue until the same result ensues; after this take care not to touch with the fingers. Use ordinary good water-colours (transparent or semi-transparent), and in rubbing down on the palette add a drop of gum solution to the water. For skin, use chrome No. 3, light red or Indian red; for shadows on the face, crimson lake. After colouring, some pour over the photo plain collodion as a varnish and to deepen the shadows; these are also deepened by brushing over with gum arabic solution.—B.SC., Plymouth.

[60787.]—**Earth Connection—Leakage.**—The connection to earth at point M would not matter unless C or L were also in connection with earth, when there would be a short-circuit on; as then, instead of going round the rest of the circuit between M and L, or M and G in the orthodox way, your current would divide itself, part going from M through the earth to C or L, and part through the circuit to the same point, as the earth circuit would be in the position of a shunt to the other, just as the field-magnets are to the external circuit in a shunt-wound dynamo, and the current would divide itself between this earth-shunt and the orthodox path through the remainder of the circuit inversely according to the relative resistances of the two paths—e.g., if this remaining part of the circuit were, say, 4 ohms resistance, and the earth-shunt 2, the current say of 12 ampères would be divided in the proportion of 2 to 4—i.e., inversely, 4 ampères going through the remainder of the circuit, and 8 through the earth. The efficiency of your battery would also be seriously altered by the diminished external resistance thus occasioned.—E. CONRY.

[60789.]—**Coil.**—This coil will give about $\frac{1}{2}$in. spark with a two cell bichromate, and $\frac{3}{4}$in. with five or six such cells. Use about 50 sheets of tinfoil $7'' \times 5''$.—S. BOTTONE.

[60789.]—**Coil.**—A good condenser for size of coil given consists of fifty sheets of tinfoil 6 by 5. The length of spark should be 1in. with everything right.—BOBADIL.

[60790.]—**Model Boiler.**—If the firebox is well stayed, so as to be as strong as the shell, the boiler will stand $\frac{1}{6}$ of $\frac{2240}{5\frac{1}{2}}$, say 70lb. per inch, allowing a strain of one ton per square inch sectional area of plate.—T. C., Bristol.

[60791.]—**Tangent Galvanometer.**—Theoretically the following equation gives the relation between the current in ampères and the deflections. In the equation c stands for ampères, d the angle of deflection, a the radius of the ring, n the number of turns in the coil, h the horizontal component of the earth's magnetism. Then, $c = \frac{a}{4{\cdot}504\, n} \text{H} + \tan d$. In practice, each tangent instrument requires calibrating separately, so as to get the value of at least, 1 ampère in degrees. The others can be easily calculated.—S. BOTTONE.

[60793.]—**Wine Cellar.**—Unless "Wine Cellar" is in the trade, it is of very little use his troubling to bond spirits. Any respectable wine merchant will supply him with a well-matured article at a fair price. Whisky blending should not be attempted on a small scale, and good distillers would not supply "Wine Cellar" unless in the trade. If he likes to advertise his address in our Address Column I shall be happy to send him address of whisky blenders where I get my own whisky (with small sample), which I consider perfection.—R. P.

[60793.]—**Wine Cellar.**—The best casks for whisky are old sherry casks. Get the stave with the bung hole in it taken out, and put the tap-hole half-way up the cask in the new one. Do not attempt to blend yourself, but get various good blends in various quarters, and mix them. Having got whisky from all over the country, and having made a most successful cask of my own (of which I will send you a sample if you like), I should recommend you to go to Messrs. Hill and Thomson, 45, Frederick-street, Edinburgh. They will show you the whiskies as they come from the various distilleries, and will blend for you. I have no interest in recommending Messrs. H. and T. or any other house. In the cases of brandy and rum, it is only a question, I believe, of getting good stuff and keeping it long enough.—OWEN H. P. SCOURFIELD.

[60794.]—**Brazing Teeth of Broken Change Wheels.**—File the broken teeth off level, screw three steel pins in the place of each broken tooth, and file them up to shape of tooth. This is far better than attempting to braze the broken casting.—THOS. FLETCHER.

[60794.]—**Brazing.**—"Young Turner" can get a new tooth put into his cogwheel, as I have seen many thus repaired.—DYNAMITE.

[60794.]—**Brazing.**—To "YOUNG TURNER:"—To repair tooth in broken spur-wheel, cut a dovetail groove where the tooth was and fit a piece of steel in, then ease off the hole a trifle at each end of the hole (like a counter-sink), and lightly "rivet" the tooth to prevent its drawing out, then trim it to shape.—T. F. S. T.

[60794.]—**Brazing.**—Cut it off flush and dovetail a wrought-iron substitute into the rim. If not, screw two pieces of iron tightly into rim, and file up same to shape of teeth.—S. M. S.

[60794.]—**Brazing.**—There is no occasion to braze this in. You cut a groove—slightly dovetail—and fit in a tooth, a snug driving fit, but not too tight. This will do all the work of the original tooth.—T. C., Bristol.

[60794.]—**Brazing.**—Don't try to braze a tooth in your change-wheel; but take a piece of steel wire a trifle thicker than your cogs, and drill and tap your wheel and screw in with good fit two, three, or four pins, cut them off to depth of cog, and then file them to shape of tooth and the repair is done.—F. G. F.

[60796.]—**Spark from Wimshurst Machine.**—"T. E. F." will find that the greatest length of spark can only be obtained from a machine in which the design contains the greatest possible lengths between the several parts; so arranged, discs of $17\frac{1}{2}$in. diameter will give sparks of $9\frac{1}{2}$in. length. For discs of 24in. diameter the stanchions of the frame ought to be 18in. apart, the bosses made to fill that space, the driving bands being near the ends of the bosses. The sectors should be 4in. long and very narrow at the inner ends; not more than twelve of these sectors on each disc, and let them be placed so as to be near the circumference of the discs; the ends of the collecting combs should not reach nearer to the spindle than the small end of the sector, and be covered with vulcanite cap. So designed, and with Leyden jars about 12in. long and $1\frac{1}{2}$in. diameter, the bottom $2\frac{1}{2}$in. coated with tinfoil, he may easily obtain sparks exceeding 12in. in length. Larger Leyden jars, or condensers, will give denser sparks, but they will be shorter.—J. W.

[60797.]—**Bookbinding.**—In reply to A. Adams I may say that the glair used in finishing needs little or no preparation. All that is necessary is to make sure that the eggs are fresh, and when breaking to be careful to keep back the yolk. If a large number of eggs are used, so as to lay up a large stock of glair for future use, the best way is to put it in bottles with a few drops of vinegar on the top of each. It will be quite thin and ready for use in a day or two, and will improve with age. But if only a few eggs are broken, and the glair wanted for immediate use, it must be well beaten. Beat until there seems to be nothing but froth. It cannot be too much beaten. Let it stand some little time, and it will all fall again and will be quite thin. In using glair, give cloth one coat only; leather work two coats, allowing the first to dry before giving the second. For large surfaces use a sponge, and for small ones, such as titles and bands, use a camel-hair brush or pencil, in every case putting on as little as possible. I could not, in the meantime, undertake to write a series of articles on bookbinding. But perhaps in a month or two, if the Editor could find space and would be willing to receive them, I might try to find the time to do so.—PRACTICAL BOOKBINDER.

[60798.] — **Fixative for Drawings.** — Gum mastic in powder, dissolved in spirits of wine, or good methylated spirit, in proportion of one drachm of powder to 2oz. of liquid, makes a perfect fixative. Shake up frequently for a few days until there is a clear, yellow liquid like sweet oil, and apply with spray apparatus.—H. P.

[60799.]—**Screw-Cutting.**—I recently gave a rule for holes in the nut before screwing. Let d be outside diameter of threads of bolt—then hole must be $d - 1\frac{2}{3}\,p$—where p is pitch of screw in inches. Thus $1\frac{1}{4}$ screw = 7 threads to inch. $\therefore$ pitch is $\frac{1}{7}$in. and hole must be $1\frac{1}{4} - (\frac{5}{3} \times \frac{1}{7}) = \frac{5}{4} - \frac{5}{21} = \frac{85}{84}$; but 1in. full would do.—T. C., Bristol.

[60799.]—**Screw-Cutting.**—The hole in the nut should be bored slightly smaller than the bottom of thread on screw, say $\frac{1}{64}$, the 64th being allowed for chasing, the bottom of thread of $1\frac{1}{4}$in. dia. being $1\frac{3}{64}$in.; therefore bore the hole to $1\frac{1}{32}$in. The actual depth of $1\frac{1}{2}$in. thread is $1\frac{1}{4}$in. and $\frac{1}{64}$in. or $1\frac{17}{64}$in.; but bore the nut slightly under $1\frac{1}{4}$in., and so in the $1\frac{3}{4}$in. actual depth of thread being $1\frac{15}{32}$in.; but boring hole in nut $1\frac{7}{16}$in., and the same with a 2in., the depth of thread being $\frac{1}{32}$in. under $1\frac{3}{4}$in., but bore the hole $1\frac{11}{16}$in.—WALLACE NEWLAND.

[60799.]—**Screw Cutting.**—A $1\frac{1}{4}$ diam. Whitworth screw has 7 threads to the inch; therefore $\frac{1}{7}$ of an inch is the depth of thread, and $\frac{2}{7}$ the size of reduction for hole in nut; but as $\frac{1}{6}$th of the original screw is rounded off top and bottom of thread, $\frac{1}{6}$th of $\frac{1}{7}$ must be added to the above size. Consequently we get $(1\frac{1}{4} - \frac{2}{7}) + (\frac{1}{6}$ of $\frac{1}{7}), (\frac{5}{4} - \frac{2}{7}) + \frac{1}{42}\,\frac{105 - 24 + 2}{84} = \frac{83}{84}$, or 1in., nearly. Any size of hole can be worked out in a similar manner, but always allow a trifle larger rather than a trifle smaller hole for your tap to work in.—DYNAMITE.

[60801.]—**Mechanical.**—Should not the heading of this query have been "Electrical"? The ratio between the resistances should be as follows: Supposing the external resistance (the plating bath) be 1 ohm, then for a series machine the resistance of armature should be $\frac{1}{20}$ of an ohm, and the field-magnets about $\frac{1}{25}$ of an ohm. If for a shunt machine, then the armature being as before $\frac{1}{20}$ of an ohm, the field-magnets should have a resistance of 20 ohms.—S. BOTTONE.

[60802.]—**Spanish.**—"Paralos" will do well to procure "A Practical Method for Learning Spanish," written by Genl. Alejandro Ybarra, and published in London by Trübner.—W. J. R.

[60810.]—**"Relief Map" of the Moon.**—Without laying claim to having had much experience in modelling lunar features, I think "S. R. C." will find plaster of Paris, or, failing this, a mixture of sulphur and whiting (in equal parts) suitable materials to work with, adding gum-water to the latter to render it plastic. As to scale, this will depend in great measure on the size and character of the formation he selects. Many years ago I made a model of *Theophilus* in plaster of Paris on a scale of about eight miles to an inch. On this scale the altitude of the loftiest peak is about $\frac{3}{8}$in. above the interior, and the general height of the wall about $\frac{1}{4}$in. A smaller scale than this would hardly be effective. A strongly-made shallow wooden tray, about 14in. square and 2in. deep, was used to receive the plaster. Templates cut out of veneer or stout cardboard, representing the cross section of the object to scale at selected points and long enough to reach from side to side of the tray, will be needed to insure the accuracy of the work as regards the height of the principal peaks, depths of interior, &c., the upper edge of the tray being taken as a datum. Of course, before commencing a model it is necessary to observe and draw the formation under as many conditions of illumination as possible, so as to thoroughly master its details. I am hoping that our good friend, "F.R.A.S." will have a word to say on this subject, as, unless I am mistaken, some years ago he dealt with a similar query in the "E.M.," though I am unable to find his reply.—THOS. GWYN ELGER.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

Since our last, "A. J. H." has replied to 60196; T. R. Allinson, 60216.

60249. Brakes, p. 587.
60251. Dipping Pewter Goods, 587.
60269. Range Finder, or What? 588.
60272. Tuning English Concertina to Equal Temperament, 588.
60278. Grape Sugar, 588.
60290. Bottle Brush, 588.
60291. Blue Bricks, 588.

60445. G.W.R. Engines, p. 95.
60461. Starch in Yeast, 96.
60471. Electric Clock, 96.
60486. Oscillating Engines, 96.

QUERIES.

[60813.]—**Narrow Gauge Railways.** — Will any reader of the "E.M." kindly inform me what is the greatest speed obtainable by passenger trains on a 3ft. gauge railway with safety, with a permanent way laid with 60lb. rails and 9in. by 5in. sleepers?—C. D.

[60814.]—**Modified Leclanche Battery.**—A few details respecting this battery (patented by Octavius March), as to voltage, resistances, &c., would oblige—PEREGRINUS.

[60815.]—**The Sun's Radiation.**—The tables furnished from the Meteorological Office give the heat recorded daily by the dry and wet thermometer, also the maximum solar radiation in vacuo, the latter being sometimes 20°, at other times 40° or 50° above the former. I shall be glad if any correspondent will point out any possible advantage arising from this knowledge. I suppose when the sun shines for any lengthened time, the modicum of air confined in the glass containing the vacuo thermometer becomes more heated than when it shines but a short time, and so gives a higher record—just as a garden plant may be roasted by placing one or more hand glasses over it.—B. R.

[60816.]—**Gas-Engine.** — Will any brother reader please assist me in the following? I am in charge of a gas-engine, which drives a 60-light dynamo, and two or three times during the evening there is an explosion takes place—something like the report of a gun: it seems to come from the exhaust box, or the air box. Is there any danger? If not, it is not at all pleasant. I have been to the makers respecting it. They came and took out the piston and well cleaned the cylinder; also reground in the exhaust valve. It went better for a short time; but now it is nearly as bad as ever.—ENGINE DRIVER.

[60817.]—**Windmills.** — Could any of your readers kindly answer the following questions? (1) In the ordinary four-sail wind corn mill, what is the amount of energy transmitted by the sails to the mill, the power of the wind being taken as 100? (2) What is the reason for the variation of the angle of sail with whip at different portions of its length? (3) Have fan-shaped sails with axis of mill at right angles to the direction of the wind and the portion below the axis sheltered ever been tried, and, if so, with what success? Any information on the subject would oblige—MOTION.

[60818.]—**Coil.**—I have made a coil 6in. by 3in., the core is $\frac{5}{8}$in. diam.; primary, two layers of 16 gauge, cotton-covered wire; secondary, about 1,000 yards of 28 gauge, silk-covered. Over the primary are two or three thicknesses of varnished paper, and each layer of secondary divided by a layer of paper and a coat of pitch and resin. I can get a $\frac{1}{4}$ spark with a small bichromate cell for a few minutes, when the platinum of the contact-breaker seems to corrode and the spark fails. I may add that the result is, if anything, worse with a large battery. The condenser is composed of 40 pairs, about 4in. square.—G. B.

[60819.]—**Portable Electric Lamp.**—I read a notice, extracted from the *Builder*, referring to the Regent Electric Lamp and Lighting Company, and giving a description of a portable electric lamp, the battery being placed within the pedestal of the lamp. If there is such a lamp, and it is not too expensive, it would be of great use in many houses. Do any of our readers know anything about it, and its value for domestic use?—MANCHESTER.

[60820.]—**Chamber Organ.**—TO MR. AUDSLEY, OR "URANIUM."—I propose, if possible, building a chamber organ, and will be greatly obliged if either of these gentlemen will assist me by advising a specification of about 12 stops for a 2-man. and pedal organ, giving scale of pipes, dimensions of instrument. Will they also state the probable cost of metal pipes and keys? I will gladly advertise my address to learn the best place to purchase pipes, &c., and to receive any hints and suggestions.—TAUBE.

[60821.]—**Battery Work.**—Will Mr. Bottone, or any of our readers, please answer the following? What chemicals are used for stripping old gold and silver-plated articles? How can I use the same over again for plating purposes? Is a dynamo or battery best for plating?—DUPLEX.

[60822.]—**Submarine Mines.**—Would some correspondents be good enough to give a description of the method employed by the Royal Engineers in marking the position of submarine mines or torpedoes? Reference to any books on the subject would also be useful.—SASSENACH.

[60823.]—**Redecorating Harp.**—I have, in my leisure moments, been amusing myself with redecorating a harp. I just rubbed down with pumice stone and sandpaper the old coat of black paint (in many places taking this paint quite off). I then repainted with about fifteen coats of very thin cream paint, made with oil and turpentine in equal quantities. Each coat I rubbed smooth with fine sandpaper. I have produced a very thin opaque and smooth result; but, unfortunately, although several weeks have elapsed, the paint, instead of being hard as I should like it to be, is everywhere very soft, so much so that if anything hard touches it it is readily indented, and anything happening to rest against any part sticks so firmly that it can only be detached at the sacrifice of the paint. Can any of your readers suggest a remedy for this, and tell me what is the kind of varnish used by professional harp decorators, and which, under their manipulation, dries hard, clear, and smooth? Would copal varnish do? Would the varnish, whatever it may be, have the effect of hardening the paint, or by drying hard and firm on the top of it obviate the defects above pointed out? I am anxious to gild some pattern, such as a vase of flowers, or a group of ornamentation, on the broad part of the sounding board on each side of the strings. Can any of your readers supply me with such a design, and tell me how it should be done?—ARPA.

[60824.]—**Dynamo.**—TO MR. BOTTONE.—I have one of Mr. Jones' small dynamos, wound as you advised, for plating—viz., No. 16 on A., and 4lb. of 20 on fields. I have been thinking of getting a second A. wound with, say, No. 30. What I want is to get as high an E.M.F. as possible, at the same time to lower the ampères as much as possible. Will you kindly say if that is the best way to get the desired effect?—F. G.

[60825.]—**Draw-Vice.**—Could any reader kindly give me a sketch of a good draw-vice for telegraph work, with sizes? I presume wires are first tightened by means of blocks. What is the best size of galvanised iron wire to use for short lines? Is standard wire easier to run than the ordinary, and is it considered better?—J. J. H.

[60826.]—**Small Dynamo.**—I am making a small dynamo. I have made armature from particulars given by Mr. Bottone in "E. M.," Vol. XLI., No. 1050; but instead of making it with twelve cogs I have made with ten, and wound it with 1lb. No. 20 s.c. wire; it is $3\frac{5}{8}$in. in dia. at points of cogs, and $2\frac{1}{4}$in. wide. Will Mr. Bottone kindly tell me what size and quantity of wire to put on poles for a compound-wound machine. The poles are 6in. high and $1\frac{1}{2}$in. in dia., made of cast-iron annealed. I also wish to know at what speed it should be driven. I have a quantity of c.c. wire, No. 16, I should like to make use of.—WILLIAM DAVIDSON.

[60827.]—**Photography.**—Could any reader kindly say if any of the recent photographic processes could be utilised for the republication of a copyright book, now almost out of print, containing diagrams, &c., and if the cost would be less than that of ordinary type reprinting?—S. R. C.

[60828.]—**Kamptulicon.** — Will any reader inform me what is used to cause kamptulicon to adhere to the wood of knifeboards, and how to prepare it?—OLD NOVICE.

[60829.]—**Electric Star Lamps.**—Will Mr. Bottone, or other friends, give me their advice if a small hand dynamo or battery would be best for this purpose: I wish sometimes to light a 16c.p. lamp, at other times four 4c.p. lamps, and occasionally a small star or fairy lamp, as worn in the hair, 2c.p., and one on the end of a wand held in the hand 4c.p.? Is it necessary to have lamps of the same c.p., or can I use the 2c.p. and 4c.p. lamps on the same leads? Batteries are such a nuisance to me, travelling about so much.—STAGE FAIRY.

[60830.]—**Jaw Chucks.**—Will any of your readers inform me how to make one—the jaws, &c.? I have the castings. It is 10in. dia., for three jaws; it is also solid round the outside. There are three slots, but no opening for the necks of the screws in the face. I have heard of them being made with two pins for keeping the screw in its place, but never saw one.—A. L. K.

[60831.]—**Photography.**—Will some of our expert photographers please inform me as to the following? About what angle, and how are for depth of focus the following lenses: Dallmeyer rapid rectilinear, Dallmeyer wide angle rectilinear, Ross rapid symmetrical, and Ross portable symmetrical? 2. I travel a great deal in the East, and am desirous of obtaining views of places I visit, and things I see; but, Oh! misfortune with dry plates. I took a batch with me this year; but the Turkish Custom-

house Officials are, in these days of dynamite, much like their Continental brethren, very incredulous, and would not allow them to pass without seeing them, the result of which spoilt my temper and the plates too. I am now desirous of preparing my own plates, and think of trying recipe given on page 442, Vol. XXXVII.; but can I make the emulsion and take it with me, so as to coat plates as I require them? If so, how is best to preserve it? Is there a more simple method than this? If so, will someone kindly give it? References to English books are almost worthless to me, as I am living nearer the Black Sea than the Thames, and, not having friends in England, it is almost impossible for me to obtain English works.—HAZIR-IM.

[60832.]—**Diatoms.**—Will any microscopist kindly assist me in the following matter? I place a little material on a slide containing diatoms under the microscope, and I wish to separate them from the surrounding matter and transfer them to a clean slide to mount them; but cannot succeed. I have tried with a sable pencil containing only two hairs; also a single hog-hair split at its end; but cannot get hold of the diatoms. I shall be very thankful for any information concerning the mounting of diatoms.—NO SIG.

[60833.]—**Micro. Objectives.**—When buying second-hand objectives, is there any means by which anyone can tell their angular aperture? Any information will oblige—NO NAME.

[60834.]—**Noise in Boiler.**—I have just had new boiler put in my kitchen for heating h.w. for bath, which makes a very unpleasant noise, sounding like someone thumping a large drum. What is the reason of this, and how can I remedy this unpleasant noise? I have searched back volumes, but find nothing relating to same.—CONSTANT READER.

[60835.]—**Analysis of Sugar.**—Will any reader kindly tell me how to make a complete analysis of loaf sugar? The sample I have is not nearly so sweet as loaf sugar usually is, and when dissolved in water leaves a slight sediment. It also appears less in bulk compared pound with pound of another sample. I can have the use of a well fitted-up laboratory, and I have done a little in inorganic analysis.—A. W. W.

[60836.]—**Electric Light.**—Will Mr. Bottone, or some other reader, inform me how many 5c.p. or $2\frac{1}{2}$c.p. incandescent lamps I shall require to light a room 12ft. square? Also, what would be the best dimensions to make a dynamo to effectually light them, keeping it as small as possible? I wish to make a dynamo whose armature will not heat, and, being a novice at this work, I shall be greatly obliged if anybody will give me the necessary information for its manufacture, or tell me of some paper which contains it. Will a quarter horse-power water-motor drive it, and at what number of revolutions should it be driven? I wish to do with as small a dynamo as possible through not having much power.—A. B.

[60837.]—**Steam.**—Would "T. C., Bristol," "Glatton," or others, kindly give me rule to find the size of boilers for small model engines? Do they stand in some proportion to the size of steam cylinder? I suppose the rule will hold good for all sizes. Also the rule to find the nominal horse-power of compound engines for condensing engines. The rule is the area of cylinder × by distance through which the steam piston travels per minute ÷ by 6,000. Does this rule hold good for compound engines? If so, which cylinder is taken?—NOVICE.

[60838.]—**Mechanics.**—A compound wheel, an axle with a diam. of 6in. and 4in., and the length of handle 20in.; would the ratio of velocity of the handle to that of the weight raised be as the following? The larger part of the axle has a circumference of 18·8496in., the smaller a circumference of 12·5662in.; the difference of these two, = 6·2832in., will be the difference which the load is raised in one turn of the axle, but the end of handle travels 125·664in. Would the ratio of the velocity of handle to that of the weight raised be as 1 is to 20? The rope hanging down forms a loop. Does the loop double the power of the machine and make it 40 to 1, or 1lb. lift 40lb.?—NOVICE.

[60839.]—**Mounting Plates of Wimshurst Machine.**—I should be glad if some of "ours" who have had experience in constructing this machine would furnish a few hints as to the best method of attaching large glass plates, say of 16in. and upwards, to the bosses. There appear to be three ways of doing this in general practice: First, having the spindle in two lengths and cementing the plate to the boss without piercing a central hole through the glass; second, a central hole in the plate and cementing to the boss; third, as recently described by Mr. Wimshurst, cementing a disc of hard fibre to the inner side of the plate and screwing up to the boss with small screws. Now, the first and second of these methods have the disadvantage that it is very difficult to get a large plate to run true. The slightest inequality in the thickness of cement (tricycle tire, or otherwise) throws the plate out of truth, and, of course, the larger the plate the more serious the error becomes. The last method offers the advantage of enabling one to true up by slackening the screws and inserting paper or other thin material between the boss and the plate; but, on the other hand, when tightening the screws again, it is necessary to be extremely careful, as a very small amount of unequal pressure results in a crack. I have been unfortunate myself in this way, having lately broken two. What is wanted is a method of mounting the plate, so that it can be safely and easily trued-up when on the spindle.—SODIUM.

[60840.]—**Oven.**—What is the best method to be adopted to construct an oven with, say, brick, to bake, say bread? It is contemplated and partly carried into effect, the following course—viz., the bottom of oven to have 2ft. of shingle, and over that 6in. of sand, and in the sand will be put the floor of oven, consisting of Bridgwater tiles; the ewens to be built with Stourbridge firebrick, laid in either Cornish fireclay or in a mortar consisting of blue lias lime and common white lime and sand; the crown of oven to be built with Stourbridge fire-brick, and each brick before it is laid to be dipped in a thin wash of Cornish fireclay and water, and after the crown is put in to lute it over the top with a wash of Cornish fireclay and water; the crown, when finally completed, to be covered with 6in. of sand, and then 18in. of shingle, and then floored for a dry with Bridgwater brick in sand. I wish to know your opinion of this arrangement, and whether you think it is a good one and will answer well? If it should be considered by anyone to be defective, and could be improved on in any respect, I should like to learn how. Two points in particular I desire information about:—whether fireclay is a good material to put the crown and ewens together with, and whether there would be any danger of its becoming crumbly and going to dust in the back part of the oven where the heat is more moderate than in other parts, and so not answering the purpose required; and also whether a mortar of either common lime and sand or blue lias and sand would answer equally well or better for the purpose of the crown and ewens than the fireclay would?—AN INTERESTED ONE.

[60841.]—**Porous Pots.**—Will someone say what is gained by using porous pots that have a high resistance, say from 2 to 3 ohms, made I believe for bichromate solutions, as such would lessen the current by increasing the internal resistance of the cell? Also, is it possible to get any difference of electro-motive force by increasing the size of cell of Bunsen battery, as I take the following from a list of batteries giving the size and E.M.F. of Bunsen cells? Thus:

Pint size	E.M.F. = 1·90	internal rest	·30
Quart size	Do. = 1·93	Do.	·26
3-pint size	Do. = 1·96	Do.	·22

I might say this is taken from the list of batteries of a big company.—C. R. N.

[60842.]—**Flat Music.**—I live in a flat. My neighbours above and below are addicted to music, and between their respective instruments my nerves are ground like grist between millstones. Music, even bad music, is not a nuisance in law, so I have no remedy in that quarter, and my neighbours decline to abate a note of their scales and their pieces. Would any reader who is skilled in mechanics or acoustics suggest a remedy? I have thought of carrying an organ-pipe from the interior of the ceiling to the interior of the floor, and of letting the players pour their noise into each other's apartments. Would that have the desired effect, or would it even partially insulate me from the sounds? My landlord cannot interfere, and I am, unluckily, bound to the premises by a lease.—D. B. MCLACHLAN.

[60843.]—**Lantern and Microscope.**—As I am contemplating the purchase of an oil lantern with microscope attachment, I should be thankful if any of our readers would give, from their own experience, any information on the following points: (1) Is it possible, with any modern oil lantern, to obtain anything like a reasonable-sized disc, say 3ft. or 4ft., with the microscope front, and using such objects as would come within the range of the 1in. and 2in. micro. objective? (2) Is there much danger of spoiling balsamed slides by the heat, as I believe this is much overstated? (3) Can such living specimens as Hydra, Volvox, and the like be shown with any degree of successs? (4) Has anyone tried Mr. Hughes' "Pamphengos" lantern for this work?—D. B.

[60844.]—**Steam.**—We have a mill six stories high. How could we heat it by steam and return the water direct back into the boiler? Would anyone please state the size of pipes? Suppose the mill to be 80ft. high, and suppose the steam pressure to be 50lb. at the bottom, what pressure would there be at the top (plain figures please)? Is steam calculated like water for pounds pressure? Also we are working a small engine in the same yard, and the distance from the boiler to the engine is 356ft.; pressure in boiler, 56lb. What pressure will then be at the end of the pipe when steam is shut off and the engine standing? I think it ought to be like the boiler pressure. Size of pipes, 2in.—FIREMAN.

[60845.]—**Polishing Silvered Goods.**—Will some of our practical readers give me full particulars how to polish articles such as spoons, forks, urns, &c., on which I have deposited a coating of silver? Also the different brushes or buffs and material required for foot-lathe polishing generally?—ELECTRO-DEPOSITOR.

[60846.]—**Electro-Deposition.**—Will someone kindly inform me of the present system in large works of the arrangement of the rods of electro-depositing vats which suspend anode and cathode? Also, how can the anodes be raised or lowered at will, or if the dynamo be used, can the anodes be wholly immersed and the current regulated accordingly? If so, how is best to suspend them for large operations?—ELECTRO-DEPOSITOR.

[60847.]—**Faulty Coil.**—I have made a spark coil; core, $\frac{1}{2}$in. by 3in.; primary, two layers of 22 cotton-covered wire; secondary, $4\frac{1}{2}$oz. of 36 silk-covered wire, insulated with one layer of paraffined paper between each layer of wire, primary and secondary well insulated from each other; condenser, 40 sheets of foil, 3in. by $3\frac{1}{2}$in. I mounted it roughly on an old coil base, and got a good $\frac{1}{4}$in. spark when connected to two chromic-acid cells—size, carbons 2in. square, two carbons to one zinc; but since I have mounted it on a new base the spark has dwindled town to 1-16in., but when the wires almost touch the spark is much larger, and covers about $\frac{1}{8}$in. of the wire. The condenser makes no difference to the size of it. What is the cause, and how can I cure it? If I have to rewind it, must I make the insulation thicker? I have tested for continuity, and find it all right.—J. MARSHALL.

[60848.]—**Electric Light.**—Will Mr. Bottone, or any other scientific reader, tell me how many 5c.p. lamps I shall require to light my workroom, 12ft. square, allowing the necessary light for a lathe? Also what size dynamo (amount of wire and dimensions of magnets and armature, &c.) I shall require to make to light them effectually. I have obtained Mr. Bottone's book on the dynamo, but should like to make an armature which will not heat. Will anyone give me the necessary information for its manufacture? I have a 1-horse-power water-motor made from Wheeler's castings. Would it give power enough?—N. S.

[60849.]—**L.N.W.R. Locos.**—What is the average time a driver is on duty daily, and how is it made up? How long running, standing, and what time consumed in shed before and after running? How long are engines usually kept in steam? Why are two tender engines, Marston 479 and Vulture 1165, kept to do shunting at north end of New-street station, Birmingham, and a saddle tank, 913 class, at the south end? What engines work Central Wales line, and what engines are stationed at Shrewsbury, Craven Arms, Swansea, Hereford, and Newport (class and date)? Can any reader give the Crewe links of passenger engines, showing number of hours worked daily by each driver? If the number of engines required each day at any station is six, how many engines would be required to be stationed to do that amount of work? What is the object of taking numbers off old engines and placing them on new ones? I saw one numbered 3050 the other day.—BALFOUR.

[60850.]—**Mid. Ry. Locos.**—What engines work Hay and Brecon Line? Where is No. 80 Midland engine, and to what class does she belong? How many passenger tanks of the 1266 class are built? What kind of passenger tanks are the M.R. building now? What is the full number of vehicles which can be drawn at a moderately fast speed by engines of the 1282, 84, 98, 121, 104, and 1747 classes? Where are the following classes of goods engines stationed, and what are their dimensions: Nos. 414, 353, 1443, 952?—BALFOUR.

[60851.]—**Sheet Wax.**—Will some kind reader inform me how to make sheet wax and how I can colour it black—something similar to what wax flowers are made of?—THETA.

[60852.]—**Gilding Glass and China.**—I have seen some glass and cheap French china goods that are gilded with a very glittering gold, and it is baked on them. I understand it is laid on with a pencil, and is in the form of a brown paint. I should feel very much obliged if some of our chemical friends will tell me how the gold is prepared, as I should like to make a little for myself.—AMATEUR.

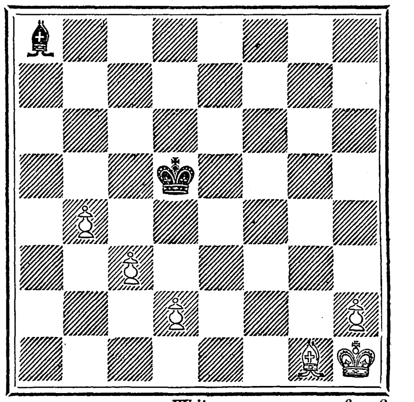
[60853.]—**Artificial Teeth.**—What are they made of, and how can I fix them on to gold plates?—E. W. GOUGH.

CHESS.

ALL Communications for this department must be addressed to J. PIERCE, Langley House, Dorking.

PROBLEM MXVI.—BY J. P. TAYLOR.

Black.



White. 6 + 2

White to play and force Black to mate in three moves.

SOLUTION TO 1,014.

White.	*Black.*
1. R-Q R 5.	1. Anything.
2. Q or Kt mates.	

(Four variations.)

NOTICES TO CORRESPONDENTS.

CORRECT solutions to 1,014, by Link, J. Mackenzie, A Dean, A Beginner, P. H. (specially good problem), G. A. A Walker; to 1,013, by J. Thompson, G. A. A. Walker, A Beginner, G. A. A. Stringfellow (but variations not given), Link; to 1,012, by Link (this arrived too late to be taken into account in Tourney list. Had it been, Link would have been bracketed 7th with F. W. S.

WHITE PAWN.—If in 1,014 2. Q-K 5, Black takes Q with B. In your attempt at 1,012, what is to prevent the Black King on the second move going to K B 5; and then how do you mate?

M. G. AND E. G. C.—Thanks for problem, which shall have attention.

RESULT OF SOLUTION TOURNEY C.

Avon, A. Bolus, I. M. B., and G. A. A. Walker, are bracketed equal with 81 marks for first prize; 5, Isca and J. Thompson, 71; 7, "——," 67; 8, Link, 65; 9, A Beginner, 63; 10, A. Dean, 59.

The following is the complete award of the *Ottawa Citizen* Problem Tourney. Two-move section: 1, Ottmar Nemo; 2, A. F. Mackenzie; 3, H. D. E. Bettmann. Best 2-er, by a Canadian, E. B. Greenshields. Hon. Men.: C. Planck, B. G. Laws, and A. F. Mackenzie. Three-move section: 1, B. G. Laws; 2, G. J. Slater; 3, J. Jespersen; 4, B. G. Laws. Hon. Men.: J. Jespersen, G. J. Slater, W. Atkinson, E. B. Greenshields, Ottmar Nemo, C. H. Wheeler.—Judge, Mr. Reichhelm.

OUR readers will be glad to learn that there is now in the press a new book by Mr. Clement E. Stretton, entitled "Safe Railway Working," which will be very shortly published by Messrs. Crosby Lockwood and Co., Stationers' Hall-court, London. The work is of a very practical character and well illustrated, and deserves to be in the hands of every railway servant.

ACCORDING to recent statistics, there are 4,570,000 more women than men in Europe at the present time.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, Nov. 3, and unacknowledged elsewhere:—

BACK NUMBERS.

WE receive so many queries asking for directions how to make many instruments and appliances which have been fully described in back volumes, that we have compiled a list, which we shall insert in this column at intervals, of those most frequently sent, and as the numbers are still in stock, new subscribers should consult the list before sending their questions.

Bookbinding : No. 613.
Electric machines : Nos. 1,009, 1,025.
Electro-magnets : Nos. 772.
Lacquers : No. 866.
Pattern Making : Nos. 938, 941, 943, 945, 948, 950, 952, 954, 955, 956, 958, 959, 962, 963, 969, 974, 978, 986, 989, 993, 995, 998, 1,000, 1,001, 1,003, 1,004, 1,008, 1,009, 1,010.
Silver-plating : Nos. 1,009, 1,010.
Varnishes : Nos. 478, 619, 675, 723, 775.

CROSSLEY BROS.—Sullivan and Co.—H. J. W.—Ajax.—Apprentice Turner.—A. T.—Fixture.—T. S.—Daylight.—Machinist.—W. M.—W. F.—Chatteris.—J. R. Campbell.—Perplexed.—J. R.—Scottie.—C. D. Barker and Co.—Torbay.—Amateur Tinker.—B. B.—E. Conry.

J. I. ISHERWOOD. (Perhaps the best "book" is Prescott's "Telephone and Electric Light," published in this country by E. and F. N. Spon, 125, Strand, W.C. There is also Du Moncel's "Telephone, Microphone, &c.," Kegan Paul and Co.; but if you refer to the back volumes you will find all the information you can require. Begin with the number for Aug. 11, 1876.)—W. B. (Sprague's "Electricity," &c., is published by E. and F. N. Spon, 125, Strand, W.C., or a lower-priced work, "Electricity and Magnetism," by F. Guthrie, Collins, or S. P. Thompson's "Elementary Lessons in Electricity and Magnetism," Macmillan. The other questions are continually receiving answers in our pages. See p. 28, No. 1016, and the indices. But why use an accumulator unless you have a dynamo to charge it? It is otherwise more costly than a primary battery.)—A MECHANIC. (Look through the indices and see if you cannot find something that will suit. It is rather too much to ask correspondents to suggest what will suit, and then tell you how to make it.)—W. J. (We have previously answered you, and referred you to the illustration of a sensitive fire-alarm in No. 1063, p. 495. See indices also. 2. The other question has also been answered many times. See, for instance, pp. 177, 260, Vol. XXXIX.)—MODEL TELEGRAPH. (If you have the instruments, surely by a little experiment you can discover how to connect them up. If you have not back numbers, see Culley's "Practical Telegraphy," which contains diagrams of all sorts of circuits and connections.)—M. NEWMAN. (Yes, it can be done; but it is not suited for the purpose. If you want a dynamo for lighting purposes, better construct one of those described in our columns.)—TRANSPARENCY. (Opinions differ. Replies to such questions would partake too much of the character of advertisements. Any good maker will supply suitable plates, or you can refer to several articles on the subject. See, for instance, No. 1091, p. 510.)—PHOTO. (No.)—J. C. O. (Perhaps it is not put in that way in the textbooks, because it is not the fact.)—W. Q. C. G. (The secretary of the institute will give all particulars.) — LEARNER. (A little gum or sugar-candy might do, but it would tend to make the ink clog in the drawing-pen. 2. For the books consult the Syllabus, or the teacher of the classes attended, or back volumes. 3. Is not the evidence of the Science Directory sufficient? 4. All particulars of the City and Guilds Institute can be obtained from the Director, Sir P. Magnus, Gresham College, London, E.C.)—R. C. H. (Parkes's "Manual of Practical Hygiene," and Guy's "Public Health," will be useful.)—PERPLEXED. (The horse-power of an overshot water-wheel is estimated by the formula $P = \cdot 00128\ Q\ h$, where Q equal the quantity of water in cubic feet per minute, and h the head of water in feet.)—W. C. (The reason is that the watch has never been compensated or regulated. A watchmaker will tell you whether anything can be done to it; but probably it is only a "cheap make," not worth spending money over.)—J. THOMAS. (If you can reduce the temperature of the whole body of water to 30° Fahr. it will freeze; but for ice to bear over water an air temperature of about 24° will be required. Are you going to produce it artificially? 2. Yes, a very large proportion of the nitrogenous matter of pulse, &c., is undigested. 3. Not unlikely. The other questions are matters of personal taste.)—MEANDER. (No room just now. Consult works on mensuration.) — CARBON. (Similar to a gas engine. Procure the patent specification, No. 8411, 1885, price 8d.)—REX. (Obtain one of the guides to Patent Law from agents advertising in our columns. A table of foreign patent fees was given in No. 939, p. 62; but any respectable agent would quote terms.)—S'UMWUN. (Read the ENGLISH MECHANIC and the electrical papers. Sprague's "Electricity" is published by Spon, 125, Strand, W.C. Many publishers issue suitable works in sound, light, and heat. 2. Try again. You have not sufficient pressure, and want a gasometer which can be weighted until a very long flame is produced.)—WILLIAM ROSS. (Write on the glass with a piece of steatite or French chalk.)—ANVIL. (The castings must be scoured quite clean with sand and the molten zinc should be covered with sal-ammoniac.) — JUBILEE. (If you have copied correctly, "Lustres ten he has completed, he reigns hitherto, and he may reign for a long while." The latter phrase no doubt is put in the form of a wish.)—INK STAINS. (If the wood has been polished, the stain can most likely be removed with water and gentle scraping; but if on the wood itself, it must be scraped out and the parts repolished.)—GALVANIZER. (Should appear in the Wanted Column. See Hints No. 4 above.)—W. A. J. (Spelter is the name for hard solder, used for brazing. It is also a commercial name for zinc, which is used for a variety of purposes—notably for lining water cisterns, for covering roofs, and for galvanising iron.)—PHOTO. (They are glazed or burnished. See p. 345, last volume, or any of the handbooks of the art.)—COOPER'S HILL. (It does not necessarily follow, but the subsequent non-appearance of the query in a few weeks would imply that demands for space were too many.)—W. T. (Why not adopt the "blue process," as it is called? See p. 85, No. 1070, and the indices. We have described most of the "graphs," and an answer to your question would open the door to a number of gratuitous advertisements.) R. A. G. (It is not easy to direct in such a matter, especially as you appear to have no documentary evidence. If you have a baptismal certificate, or can search the register of births at Somerset House, you could probably trace the marriage of your father; but when that is accomplished it will be difficult to discover whether he has any relations without making personal inquiries in likely directions. As you have an address, the marriage might have taken place in that neighbourhood, and by searching the registers you might gain some information.)—ONE IN A FOG. (You must give some idea of the construction of the machine, and explain what you mean by "loses its magnetism.")—C. MOORE. (Boil a little yellow resin in linseed oil.)—L. T. (Kindly look through the indices of back volumes. An electric railway has been in use for some years at a mine in Germany. See No. 943, for instance.)—JAS. BRADLEY. (The paint is mixed with copal varnish.)—J. D. N. (Beeswax is bleached on the large scale in a steam-heated vat, by means of water, bichromate of potash, and sulphuric acid. The simplest way is to melt it with water at a low temperature, and boil for a few minutes. Withdraw the heat and sprinkle over the wax, very carefully, a little oil of vitriol, say, 3 or 4 fluid ounces to the cwt. of wax. Cover, and allow to settle; then skim off wax with a warm ladle, and place in shallow vessels so as to obtain thin cakes of the wax. These are exposed to the action of sun and air to bleach, and are remelted two or three times when wanted very white.)—A PUZZLED ONE. (Did you commence without knowing the proportions or anything about the process? See p. 298, No. 949, and the indices generally, or procure a pamphlet from the Greenbank Alkali Company, St. Helen's, Lancashire.)—W. P. (For sketches of detective money till, see pp. 228, 387, Vol. XL., and also pp. 455, 477, 500, 522, for a discussion of the subject.)—AN OLD FRIEND. (Ahn's system, Hamilton's, and many others which you can probably see at a large bookseller's in Belfast.)—W. R. (See indices, or the catalogue of the makers. The amount of fall or head of water must be known, or, in other words, the pressure, before advising about hydraulic motors.)—PYROLOGIST. (We think not; but if so, Messrs. Trübner, Ludgate-hill, or Messrs. Crosby Lockwood and Co., Stationers' Hall-court, E.C., can tell you.)—E. E. M. (The fee for an ordinary search at Heralds' College is 5s., for a general search one guinea. Apply to the Registrar at the College, Queen Victoria-street, E.C.)—BLOWPIPE. (The solder will not run until the metal on which it is placed becomes hot. See indices under head of "Blowpipe, Brazing, &c.," or send a definite question.)—K. M. ROTER. (You can only summon him to the County Court. Bills of sale are registered at the Central Office of the Supreme Court.) —BAHADUR. (Vulcanite, ebonite, &c., are polished with rottenstone and oil on a buff, using a little water occasionally to keep the vulcanite cool. The finish is put on with the hand and dry rottenstone. 2. Any dealer will supply suitable paper. 3. Rather incomprehensible. Practice seems to be all that is wanted. 4. Answered above, except that in the case of "sheet" flat rubbers are used.) — SOUTH COAST. (Any builder of bakers' ovens will supply one. We do not send sketches. See Hints above. 2. How can we give instructions without a plan of the place—without, in fact, doing the work of the engineer? See No. 864, p. 141, and the indices generally. It is always difficult work where the place to be heated is below the level of the boiler.)—C. L. OR N. (Spence's "Geography," published by Crosby Lockwood and Co., Stationers' Hall-court, E.C., 2s. 6d. 2. Oxalic acid will start any iron ink; but see indices. 3. How can anyone say without seeing the tooth? 4. Brush them over with glair. Or do you mean re-cover?)—PHOS. (Prescott's book on the Telephone, &c., is published by E. and F. N. Spon, 125, Strand, W.C.; the International Scientific Series by Kegan Paul and Co., Paternoster-square, E.C.)—ZERO. (See the indices for many replies on dynamos. The dimensions are very much the same as those described in his book. See p. 256, No. 974.)—H. EYRE. (Boil some lime-water in it, and so get a coat of fur. The water you use is soft and probably peaty. If you get a good coat of fur on by boiling hard water in it, that will prevent rust for a time.)—LEARNER, J. P. (We believe we answered you not long ago. The art is described in many books, but has scarcely a special treatise devoted to it. Both hard and soft soldering have been frequently described in back volumes.)—CHICKING REARER. (The incubator was illustrated and described in No. 935.)—W. H. W. (Very little in a properly arranged loco.; but it can be ascertained only by means of the indicator. 2. It has been given so many times, and can be obtained from the makers. The original Willans engine was illustrated in No. 497, p. 61.)—NELLIE. (For some there is no effective remedy, but a toilet vinegar to remove summer freckles is made on the large scale as follows:—6,500 parts of vinegar have 1,350 parts of lemons cut up small into them, and there are then added 850 parts of alcohol, 225 of oil of lavender, 5 of rose oil, 60 of cedar oil, and 850 of water. The mixture should be exposed to the sun for three days; then filter. Apply with a sponge at night and let it dry. Wash with cold water next morning.)—LEARNER, Galashiels. (If received, it was answered in some form. The question is not of general interest. There are the Finsbury College, the School of Telegraphy, and, we think, one good school in Glasgow and Edinburgh. The B.Sc. would be an advantage; but you do not say what you mean by "electrical education.")—F. STRIFFLER. (Thanks for fresh copy of illustration; letter shall appear next week.)—A SOCIALIST (In type).

ADVERTISEMENTS in the SIXPENNY SALE COLUMN.

	s. d.
Sixteen words	0 6
For every succeeding Eight words	0 6

*** It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions and in cases where the amount sent exceeds One Shilling, the Publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O.'s.

The address is included as part of the advertisement, and charged for.

Advertisements *must* reach the office by 1 p.m. on Wednesday, to insure insertion in the following Friday's number.

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

6s. 6d. for Six Months and 11s. for Twelve Months, Post Free to any part of the United Kingdom. For the United States, 13s., or 3 dol. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office Order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. JAMES W. QUEEN and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII., XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX., XL., XLI., XLII., and XLIII., bound in cloth, 7s. each. Post free, 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post free from the office (except index numbers, which are 3d. each, or post free, 3½d.).

Indexes for Vols. I., VI., VII., VIII., and IX., 3d. each. Post free 2½d. each. Indexes to Vol. XI., and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

OUR EXCHANGE COLUMN.

The charge for Exchange Notices is 3d. for the first 24 words, and 3d. for every succeeding 8 words.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
FRIDAY, NOVEMBER 12, 1886.

NOTES ON NEBULÆ.—IV.

G. C. 5030 (A.R = 23h. 49m., Dec. N. 60° 37′).—Very faint nebulous cluster, condensed in centre = 11 mag. star; several small stars near. Very cometary aspect (power, 100 on 10in.). May 1, 1886.

G. C. 4907 (H II. 706. 23h. 7m. Dec. N. 60° 46′).—Described by H. as "very faint, large; two pretty bright stars involved." This is a very fair description. Only, now the nebula seems more on the preceding side of the stars, and there is apparently a *very faint* star near the centre of the nebulosity, i.e., just preceding the double star; several bright stars near, especially a curious combination of 11mag. stars a short distance preceding. May 3, 1886 (10in, 100). D'Arrest says:—"Proxime subsequitur * duplex (12m. = 12m. dist. 33″; △ A.R. 2·7s. seq. bor.), quarum altera nebulæ adhærere videtur, alterum vero manifesto a neb. liberam esse putem. Ejusdem fixæ mentio fit a. 1787. H hæc res quondam duplex major apparent."

G. C. 4487 = 2037 = H III. 743 (19h. 11m., Dec. N. 6° 17′) August 6, 1886, 10in., power 100.—A very curious object. Rather faint and large, ill defined, about 1′ diam. Slightly brighter on the *s.f.* side, and having apparently a darker centre, giving it an annular appearance. An excessively faint star, close (almost in) the *n.f.* edge (D'Arrest says, "Per amplificatio 356 alia * minutissima, 16 mag., apud marginem nebulæ orient. bor. conspicitur"); and a 12 mag. star about a diam. *n.f.* (D'Arrest, "* 13 ord. seq. 6s. ad boream in angul. posit. 37° 3′."). Edges of nebula very ill-defined; will not bear high powers, 80, 100, and 150 only used. The description given in the G.C. is "planetary, faint, large, round, very suddenly brighter to the middle disc; small star *n.f.*," which agrees pretty well excepting as to the brightening to the centre. Without doubt (as also in D'Arrest) the nebula is now *darker* in the centre. Is it possible that the faint star now on the *n.f.* edge can have been in the centre when seen by Herschel?

G.C. 4572. H IV. 16 = *h*. 2075 (20h. 16m., Dec. N. 19° 40′), Aug. 6, 1886 (10in.).—A pretty bright planetary (?) nebula, with appearance of a nucleus (star?) slightly oval, 20″ diameter; edges ill-defined, exactly between two stars (10 mag.) about a diam. south, and same distance north, a 12 mag. star. Power 320. Aug. 25, 1886. Not planetary, but bright compact nebula, very woolly at edges; diameter of nebula 40″—50″. The nucleus is gradually brighter, and is placed more on the following side of the nebulosity; an 11 mag. star follows at a little distance. At times a suspicion of a minute stellar nucleus. Power 320. D'Arrest says: "Lumine satis æquabili cum duobus punctus paullo lucidioribus excentrice insites."

G. C. 4514 = 73 H IV = *h* 2050. (19h. 41. Dec. N. 50° 11′). Aug. 11, 1886. 10in.—A bright quite circular nebula, about 30″ diameter, fading off at edges. A 10 mag. star exactly in the centre. Sharp with low powers; but apparently a little ill-defined with high ones. An excessively faint star on prec. edge of nebula, a little north. (D'Arrest does not mention this star.) A 12 mag. star a little distance south, and a fainter 13 mag. star at a good distance N. Two very faint stars follow at some distance a little S. To me this nebula appears different in character from 37 H IV. Seeming a globular nebulosity, brightening from edges to centre, although D'Arrest says "Gemina est nebulæ planetaris H IV 37, nisi quod fixa in centro clarius elucet." Powers used, 80, 320, and 1,400.

G. C. 4390. Σ 6 = *h* 2000. 18h. 5m. Dec. N. 6° 49′. Aug. 26, 1886. 10in.—A wonderful object. Exceedingly bright. Exactly like an ill-defined star with low powers; with higher ones rather elliptical N. and S. Small, not over 10″ diam. (D'Arrest says 5″—6″), edges a little uncertain; condensed to centre. Almost a star-like nucleus, but lost in the brightness, perhaps a very little haze surrounding the whole. An excessively faint star *n.p.*, the nebula almost in the edge. With a direct-vision prism, the nebula appeared monochromatic, and very different from the bright 9mag. star following at a little distance. The brightness of the nebula = 8mag. star. Powers 100 and 320.

G. C. 4625. H 152 = *h* 2097. (20h. 54m., Dec. N. 15° 38′). Globular, rather compact nebula, bright, with low powers (100); but with 320 apparently resolved, like the nebula near β Androm. It seems to be a feeble distant cluster, a 12 mag. star at some distance *s.p.*, and a 14 mag. star about two diameters of nebula *n.p.*, and the same distance *n.f.*, and a suspicion of an excessively minute star just following the nebula. August 26, 1886; 10in.

G. C. 4678. M 2. (21h. 27m., Dec. S. 1° 22′). A grand, brilliant, compact cluster of very minute stars, a perfect blaze in centre. The stars comprising it are unusually equal in size, and rather more scattered toward the south side. A bright 10 mag. star *n.f.* the cluster. A faint 12 mag. Double (10″ ±) following. Powers 100 and 150. Aug. 30, 1886.

G. C. 4585. H I 103. (20h. 26m., Dec. N. 17° 16′). Brightish nebula about 3′ diam. with low power, but with higher (320) apparently resolvable much brighter to the middle to a granulous nucleus. A bright 9½ mag. star precedes at about 1½ diameter of nebula, and a faint 12 mag. star follows at a greater distance.

A.R. = 19h. 42m. (Dec. N. 11° 17′ ±) a cluster of 12 mag. stars apparently mixed with nebulosity, especially towards the *s.f.* side, abont 2¼′ in diameter. It is easily found on sweeping a little east of π Aquilæ. This, I thought, was new, having found it by sweeping, Sept. 1st, 1886: but I am informed by Mr. Herbert Sadler that he has seen it before.

G. C. 385. 76 M. (1h. 33m., Dec. N. 50° 52′.)—A double nebula (P = 45° ±) nearly equal in size, but the preceding quite twice as bright as the other. An 11 mag. star precedes, and another follows at twice the distance, a faint double star a little north. No nucleus in either nebula. Diameter of each about 60″. They are quite joined by nebulosity. No star very near nebula. Sept. 1st, 1886; 10in. Powers 100 and 150.

G. C. 4561 H IV 72 (20h. 7m. Dec. N. 37° 59′).—This is a most interesting object. An excessively faint wisp or ray involving and extending in a *s.p.* direction from the beautiful double star O Σ 401 (7½ and 10 yellow and purplish). The nebula is *exceedingly faint*, about 8′ long and 1′—1½′ broad. Mr. Sadler mentions this nebula in his interesting letter (ENGLISH MECHANIC, No. 1,109, letter 25881) on one of MM. Henry's photographs of part of Cygnus. He says that Holden did not see the nebula with the 15½in. Washburn refractor, and neither O Σ nor Dembowski mentions it; but this is not surprising, as their object being the observation of the double star, the power used was probably too high. He says that according to the Parsonstown observation the nebula extends on both sides of the double star. On the print of MM. Henry's photograph (which Mr. Sadler most kindly lent me) no trace is seen of the nebula. When I examined the object in July of the present year with the 10in. dialyte and power 100, the nebula was seen to extend certainly only on the *s.p.* side of the double star. This was confirmed by just shutting out the star first on the *s.p.*, and then the *n.f.* edge of the field; some faint stars not shown in the photo-print were seen in the telescope. Why is this placed in Herschel's fourth-class nebulæ? It is quite of the character of 19 H V. Andromedæ, which from its faintness and large size is easily missed with a moderately high-power.

G. C. 1541. H 44 V. (7h. 23m. Dec. N. 66°).—Cometary, large bright, two 10 mag. stars touching the nebula *n.p.* and *s.f.*; brightening towards the centre to a small nucleus = 12 mag. star, a little following the line joining the two stars; the coma extends more to the north of the nucleus. It is described in the G. C. as "considerably bright; exceedingly large; very much elongated; very gradually much brighter to middle to a nucleus 7″." It is a little curious that no mention is made of the two bright stars which are really involved in the outskirts of the nebula. Sept. 30, 1886, 10in. P. 100.

G. C. 463 H I. 112 = *h* 181 (1h. 51m. 39s., Dec. N. 19° 20′).—A very pale and not very bright nebula, slightly elongated (P = 100° ±). About 1′ × 1½′ cometary, an uncertain condensation in centre, but not sharp. Powers used 100 and 200; a 12 mag. star about 5′ S. Sky not quite clear (Oct. 29, 1886).

G. C. 2158. H IV. 60 = *h* 731 (10h. 29m., Dec. N. 54° 14′).—Pretty bright round nebula; not planetary; about 40″ diameter; gradually brightening towards the centre, in which a patch of about 10″—15″ equally bright—forms a sort of nucleus; no star near, the nearest a 12 mag., about 3′ N., and a 13 mag. at a rather greater distance *s.p.* (Sky hazy). Powers used 100 and 200; 10in; October 30, 1886.

Herbert Ingall.

REVIEWS.

A Complete Treatise on the Art of Retouching Photographic Negatives. By ROBERT JOHNSON. London: Marion and Co.

THE arts of negative retouching and of working up photographs in colours or monochrome are not to be acquired without considerable practice; but those who are possessed of the requisite artistic taste will find their labours immensely facilitated by a study of Mr. Johnson's work. The author has had many years' practical experience of his subject in the best photographic establishments in this country, and as he writes in a clear style, and explains what he means by the aid of lithographs, we can recommend this work to all who desire to learn the art of retouching negatives and "finishing" photographs. Almost indispensable to amateurs, it will be welcomed by professionals, for no previous work has treated so thoroughly and so practically the important subjects of retouching and colouring.

Abridgments of the Specifications relating to Velocipedes. By ROBERT EDWARD PHILLIPS, M.I.M.E. London: Iliffe and Son.

PERHAPS the chief complaint made against the establishment known as the Patent Office is the dilatory manner in which the officials look after work that it is of importance to would-be patentees and their agents should be done well and promptly—e.g., the publication of the abridgments of specifications. Mr. Phillips makes a speciality of cycling patents, and has therefore felt the want of a work which would give in a concise form the special features of all patents relating to velocipedes. He has boldly tackled the task himself, and pertinently says that if other agents would make abridgments of the class of patents with which they are most intimately connected, the officials would be put to shame for the disgraceful state into which they have allowed their abridgments to lapse. The present volume contains abridgments

from 1818 to 1883, when the illustrated journal was issued from the Patent Office; but Mr. Phillips intends to issue appendices from time to time, thus keeping the work as far as possible up to date—indeed, the volumes for 1884 and 1885 are "in the press." Makers of machines, inventors, and patent agents are indebted to Mr. Phillips for the trouble he has taken to compile this list and then publish it for the benefit of all concerned.

A Textbook of Steam and Steam-engines. By ANDREW JAMIESON. London: Charles Griffin and Co.

THIS work is the result of gradually improved lectures delivered to the students of the Glasgow College of Science and Arts, and is intended to bring the information step by step within the grasp of its readers. Although not by any means a mere cram book, it is excellently adapted to the wants of those who intend to sit for the examinations of the Science and Art Department, and of the City and Guilds Institute, for while the Lectures themselves contain all that is needed to obtain a thorough knowledge of steam and the steam-engine, the questions appended at the end of each lecture will give an idea of what is required of candidates who go up for the examinations referred to. Students for honours are also advised to consult the works mentioned in notes and the appendix for information which could not be given without unduly augmenting the dimensions of Mr. Jamieson's useful textbook. The examples of boilers, engines, and accessories are, as a rule, well selected, and if students will carefully read the Lectures and endeavour to answer the questions at the end, they need have little fear of not passing any of the examinations for which they can sit.

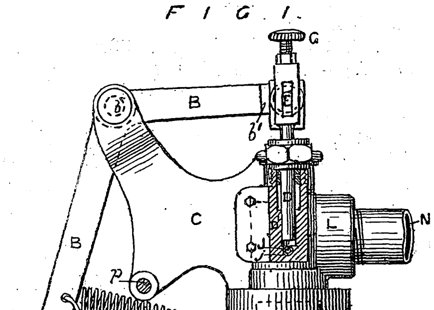
WE have also received *The Watch and Clockmaker's Handbook, Dictionary, and Guide*, by F. J. BRITTEN (London: Kent and Co.), the sixth edition of a work which is almost indispensable to all watch and clockmakers. In this new edition much useful technical information has been added, and several tools and devices of recent invention have been described for the first time.—*Geometrical Drawing for Army Candidates*, by H. T. LILLEY, M.A. (London, Paris, New York, and Melbourne: Cassell and Co.), is a little work in which the problems are classified in groups suggested by an analysis of examination papers, and arranged according to the principles involved in their solution. The author has indicated about 180 problems, which in his experience form a suitable "first course" for the majority of students. —*Lessons in Elementary Dynamics*, by H. G. MADAN, M.A. (London and Edinburgh: W. and R. Chambers), is a valuable little book which will even interest schoolboys in the laws of matter and motion, because the facts are put forward and explained in a simple, straightforward way.—*Ausa Dynamica: Concerning Force, Impulsion, and Energy*, by JOHN O'TOOLE (Dublin: Hodges, Figgis, and Co.), is an improved and enlarged edition of "Mr. O'Toole's" clever book, in which the author insists that none of his strictures can be properly called hypercritical, and respectfully suggests that the dynamicists would do well to revise and rearrange the phraseology of their science. There are many points in Mr. O'Toole's brochure which will interest students and doctors of Dynamics. — *The Practical Manager's Slide-rule Companion*, by JOSEPH HOVELL (Dundee: J. P. Matthew and Co.), is a collection of examples of the use of the slide-rule in making all sorts of calculations.—*Euclid Revised*, Books I. and II., Edited by R. C. J. NIXON, M.A. (Oxford: Clarendon Press; London: H. Frowde), will be welcomed by many teachers, and possibly also by a good many examiners. — *Chemical Arithmetic*, by SYDNEY LUPTON, M.A., F.C.S., F.I.C. (London: Macmillan), is the second edition revised of a useful little work which has been reduced in size and price.—*Cottage Building*, by C. BRUCE ALLEN (London: Crosby Lockwood and Co.), is the 10th edition revised and enlarged of a little treatise in Weale's series which may be useful to those who wish to erect cottages on their property. —*Practical Dynamo Building for Amateurs*, by F. W. WALKER (London: Iliffe and Son), will perhaps be recognised by our readers as a series of papers which appeared in our last volume. — *The Wood Carver*, by J. S. GIBSON (Edinburgh: Scott and Ferguson), is a collection of 34 full-size designs, with instructions for practising the art of wood carving, which are sufficient for anyone determined to succeed. — *The Wayfarer* (London: Chatto and Windus) is the journal of the Society of Cyclists, which, besides information of interest to the members, contains several readable papers on miscellaneous topics.—*Report of the United States Fish Commissioner for* 1883 (Washington) is a ponderous volume of over 1,200 pages containing an "inquiry into the decrease of food-fishes, and the propagation of food-fishes in the waters of the United States." It is full of useful information, including a detailed description of the *Albatross*, the United States Fish Commission steamer.

WE have also to acknowledge the receipt of *Electricity in the Service of Man*, from the German of Dr. VON URBANITZKY, edited by R. WORMELL, D.Sc., M.A. (Cassell and Co.); and the *Gas-Engine*, by DUGALD CLERK (Longmans); *The Modern Practice of Shipbuilding in Iron and Steel*, by SAMUEL J. P. THEARLE (London and Glasgow: W. Collins, Sons, and Co.), Vol. I. (text) and Vol. II. (plates).

SPIEL'S PETROLEUM ENGINE.

ENGINES which work by the explosion of vapours derived from petroleum do not differ much in their general arrangements from gas-engines, but the valve and governor gear are almost of necessity rather complicated. We illustrate in the annexed engravings the

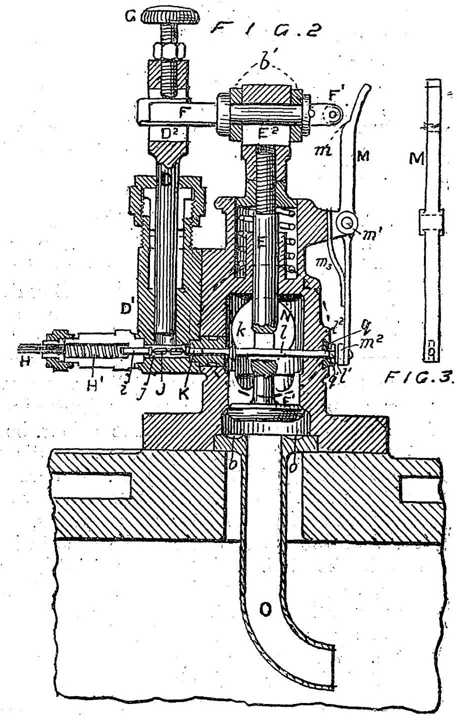
FIG. 1.



principal features of the Spiel petroleum engine, which represents the improvements adopted and recently patented. In these improvements, the action of the governor prevents the engine running too fast, by interposing a slide between the pin whose function it is to open the supply valve controlling the port through which the combustible is injected into the mixing chamber above the cylinder, the thickness of which slide shields the projecting supply valve spindle, and receives the tap of the opening pin. The improvement in the slide-valve consists in fitting it with an adjusting screw, by means of which the narrow port along which the supply of compressed combustible mixture passes from the cylinder to the flame cavity in the slide during the stroke of the latter, may be regulated with respect to its sectional area. Fig. 1 is a front elevation, partly in section. Fig. 2 is a longitudinal section through the axes of the combustible pump and air-valve chamber, from the flywheel side of the engine. Fig. 3 is an elevation of the tappet lever of Fig. 2.

A is the way shaft driven from the crank shaft at half speed, and a the cam for actuating the supply gear. B is a lever having its fulcrum at b, in an extension of a bracket C standing across the engine cylinder. C^1 is a returning spring. The lower (and longer) arm of the lever is fitted with an anti-friction roller to insure a smooth action between the cam and it. The upper (and shorter) arm is split into a fork b^1. D is the ram of the combustible pump D^1, and E the spindle of the air valve E^1. Both of these are connected to the lever B by a crosshead F carried by the lever and passing through a slot in the head of the ram and spindle respectively. G is a screw by means of

FIG. 2. FIG. 3.



which the depth of the slot D^2, and consequently the play of the crosshead therein, may be adjusted for the purpose of regulating the length of the stroke made by the ram D. H is the combustible supply terminating in a short pipe of enlarged bore, in which lies a spiral spring H^1 always bearing against the pin of the suction valve i. J is a pin lying centrally in the port j. K is the delivery valve, k a pin terminating in a conical extension, and l a pin, the end l^1 of which projects beyonds the face of a grooved extension l^2 formed upon the side of the cylinder L in which the air valve works, while the valves i and K are kept in a central position by webs formed upon these spindles. Similar webs are also formed for the same purpose upon the pins J and k. The spring H^1 keeps the aforesaid lines of pins and valves in constant contact, and when free the suction and delivery valves i and K, the former open and the latter shut. The rise of the crosshead F closes the air-valve E^1 and makes the ram D draw in a supply of combustible. The return of the crosshead down the slots D^2 E^2 in the respective heads of the ram D and spindle E, leaves the latter at rest for a short time while the projecting end F^1 of the crosshead engages with the shoulder m of the vibrating leader M having its fulcrum at m^1 in a projection from the cylinder L. The lower extremity or tapper m^2 of the lever is, accordingly, forced against the projecting end l^1 of the pin l which is drawn in, thereby opening the delivery valve K and closing the suction valve i against the spring H^1. While these valves are maintained in this last described position by the continued contact of the crosshead end F^1 with the adjacent face of the lever M, the continued

descent of the crosshead causes the ram to make its down stroke, injecting the charge of combustible through the port j and past the conical extension on the end of the pin K into the cavity above the valve E^1, where it meets with the air supply coming in at the pipe N, with which it is thoroughly incorporated, such incorporation being facilitated and rendered perfect by the comminution to which the combustion is subjected during its passage from the foot of the pump D^1 on to the valve E^1. This latter is opened at the same time that the injection of the combustible is being effected, and the mixed combustible and air pass the valve into the working cylinder of the engine along the pipe O. The gutter o round the top of this pipe gives an upward tendency to the compound vapour passing the valve E^1, and therefore acts as a further intermixing agent upon the particles of air and combustible. A slide is connected to a crank on the end of a rod geared to the governor. The opposite end of the slide works in a groove in an extension, the nose of the spindle passing through a slot formed in the end q^1. Upon part of the face of the end q, there is an outward extension q^1, the projection of which beyond the extension l^2 is not less than that of the spindle end l^1. When the governor begins to race, the crank moves the extension q^1 between the tapper m^2 and the spindle end l^1. The next tap of the tapper will therefore fail to reach the spindle end l^1. The next upstroke of the ram D will draw in a supply of combustible through the pipe H^1, which will be returned along the same by the following down stroke of the ram. The consequence will be a cycle of motion without an explosion in the cylinder. The speed of the engine will then decrease, and the slide P be drawn back, thereby allowing the tapper m^2 to act upon the suction and delivery valves in the normal way as above described. The flexibility of the lower half of the lever M prevents its being distorted when the extension q^1 prevents it making its stroke. The returning spring m^3 needs no detailed explanation.

TRIPLE-EXPANSION MARINE ENGINES.

It is not so many years ago that a considerable number of engineers could have been found who would have asserted that the compound engine could not possibly be more economical than the single type, and that any advantages discovered in actual practice were due entirely to the higher pressures of steam employed. That high pressures tend to economy is well known, because they facilitate expansion; but, so far as the average shipowner is concerned, it is a matter of no importance to him how the economy is effected so long as he can propel his vessel a given number of miles for a lessened consumption of coal. Just as the single engine went out of fashion for marine purposes years ago, so the compound, or the "simple compound" as it is called to distinguish it, is being supplanted by the triple-expansion engine, and it is not unlikely that quadruple expansion will be adopted before long by some of the more adventurous engineers. At the recent meeting of the Institution of Mechanical Engineers at Leeds, only one paper was read—that by the late Robt. Wyllie, of Hartlepool, on triple-expansion engines — which led to so lengthy a discussion that its further consideration was postponed until the next meeting. As a contribution to the literature of this subject Mr. Wyllie's paper is perhaps the most interesting that we have had for some time, and though the theoretical points will be argued pro and con. by engineers, the fact remains that the high-pressure triple-expansion engine is the successful rival of the double-expansion compound, so far as "orders" are concerned, and orders for marine engines always follow a lessened coal consumption, which can be easily understood when it is mentioned that of two sister ships making the voyage to Australia, one consumed 1,200 tons of coal less than the other. As to the position of the three cylinders, considerable difference of opinion prevailed until Mr. Wyllie undertook to construct an engine of 700 I.H.P. which should occupy no more space than an ordinary compound. His experience taught him that to take full advantage of the triple-expansion system, the cylinders must be so placed as to drive three cranks at equal angles, and in his paper he says that the most important conditions are approximate equality in the range of temperature in each cylinder, in the initial stress on each crank, and in the indicated H.P. of each engine. As regards steam jacketing—a vexed question in connection with marine engines—Mr. Wyllie considered that the benefits to be obtained were naturally not so great with a triple-expansion engine as with a single engine having a high ratio of expansion; but he held that the jacketing of the intermediate and low-pressure cylinders is essential to maximum efficiency, while there are mechanical advantages in having the working barrels of all cylinders cast separately —for new liners cost comparatively little. Mr. Wyllie's paper contains several tables of performances of triple-expansion engines, and a number of indicator diagrams, so that it is a valuable contribution to the subject; but although there is no doubt of the economical working of the triple-expansion engine, we must wait awhile before it will be possible to ascertain how it stands when repairs and cost of maintenance can be entered as items in the comparison. Mr. Parker, of Lloyd's, says that from facts gathered from shipowners and marine-engine builders, it has been conclusively shown that the ships in which the highest pressures are carried are the most economical steamers, and so far no one has yet shown us how to utilise high pressures without the three-cylinder expansion. According to Mr. Parker, the consumption of coal has been reduced quite 30 per cent. within the last five years, and he instanced two large P. and O. steamers of exactly the same dimensions, but one having the triple engine working at a pressure of 145lb., and the other an ordinary compound and a pressure of 90lb., where the latter consumed 1,200 tons more coal than the former in completing an identical voyage. Such a fact as that, which is of course known without any chance of error, explains the anxiety of owners to adopt the higher pressures and triple expansion. One of the speakers, indeed, said that he was working engines at 180lb. and even 200lb., and he expressed an opinion that with still higher pressures four and perhaps five cylinders would be required. Prof. A. B. W. Kennedy dealt with the question from a theoretical point of view, and also by calculating the steam consumption of six vessels from indicator diagrams, which he says always make the steam quantities too small. The statements of averages cannot, he says, be trusted entirely, and he hopes it will be possible to secure more accurate data, for he believes that some of the indicator diagrams examined by him do not show more than about 75 per cent. of the steam actually used. In working out some diagrams as much as 16lb. of water per pound of coal was found as the evaporation; but Prof. Kennedy says that is impossible, for with ordinary coal, such as is burnt in marine boilers, only 12 to 14lb. of water per pound of coal could be obtained in a calorimeter, while, owing to imperfect combustion, loss of heat, &c., 10lb. of water evaporated per pound of coal is really very good practice in boiler furnaces. Such advantages as have been obtained by the use of triple-expansion engines are believed by Prof. Kennedy to be due entirely to the use of higher pressures of steam, which enables us to take additional work out of the steam by expanding it from 150lb. down to 45lb. There is no theoretical reason why this additional work should not be obtained in two cylinders; but there are important practical reasons connected with range of temperature and initial condensation which make it difficult to utilise with advantage so high an initial pressure as 150lb. in two cylinders only. The economy of the triple engine being thus due to the increase of steam pressure, it may well be asked where is the limit at which this development will or must stop? If 150lb. gives an economy which is so much appreciated that shipowners take out good engines and replace them with others of the triple-expansion type, will not 200lb. give more economy still? and if three cranks distribute the strains more equally, will it not be better at once to go boldly to a quadruple-expansion engine and have four cranks? These are questions for practical marine engineers and experts, for it is certain that shipowners, knowing and appreciating the economical value of high steam pressures, will insist on having pressures as high as can be carried with safety. If the Perkins system is a practical success, now is the time for those who believe in the possibility of using such high pressures to come forward and take, not merely a step, but a leap in advance. Considering the enormous amount of coal consumed by the latest types of Transatlantic liners, there is a wide field in which to practise any economy that can be devised.

THE AMATEUR WORKSHOP.—XXIX.

Circular Saws.

A CIRCULAR and a band saw must be considered indispensable accompaniments of a modern workshop, the first for ripping and cross-cutting, the second for sweeps. I will describe a circular saw alone in this article, and then in the next illustrate a combined circular and band saw, not because I am much in love with combination machines, but rather on account of their special adaptation to the requirements of an amateur workshop.

First then, in reference to the circular, it is well to remark that for power-driven saws the almost universal practice among the best makers is to adopt what is known as the "solid-box framing," that is, the whole of the standard framework is in one casting instead of being made of separate pieces or frames bolted together, the advantage of this consisting in the superior rigidity and freedom from tremor which this design possesses. But I do not recommend the adoption of this design to the amateur, because of the amount of work involved in the pattern making. Neither is it of much consequence in the case of a light machine, even though driven by power, and certainly is not necessary for a hand machine. The framing which I have chosen as being easy of construction, yet quite rigid, is that shown in Figs. 319 to 321, and details. Almost any common wood will do for the framework excepting those kinds which are given to twist, as elm, for example. Dry beech or birch among the hard woods, red deal or pitch pine among the soft woods will suit equally well; or the frame may be of soft, and the table of a hard wood.

The mode of construction of the bench is apparent on an inspection of the figures. There are, first, the two side frames, or standards A, maintained rigid by the four distance pieces or stretchers B, and sustaining the four cross bars C, upon which the boards forming the table are placed, and to which they are screwed down, the framework itself being steadied, and held with bolts as shown. The table is supposed to be removed from the frame in the plan view (Fig. 320), the better to show the spindle and timbers. The different joints are outlined in detail (Fig. 32?), and the dimensions given are suitable for a saw of moderate size, or not exceeding 12in. The size of the bench could be easily increased or reduced at pleasure, the proportions remaining about the same. The side frames will be first made, and put together, and afterwards united by the stretchers, cross bars, and bolts. The tenons must be a good driving fit, and their shoulders square and straight and closely abutting. Then when the bolts are tightened up there will be no fear of the structure rocking unsteadily. The diagonal braces will prevent alteration of form taking place in the frames themselves, and movement in the transverse direction will be prevented by the good abutment of the stretchers, and by the firm bedding and screwing down of the cross bars on the tops of the frames. The whole structure is bolted down to the floor by bolts passing through the ends of the bottom rails of the frames. The table will be more conveniently described presently.

The common form of saw spindle is shown in place on the timber framing, and also enlarged in Fig. 323. It consists of a shaft running in long bearings, the latter being prevented from becoming improperly set or atwist by being cast on a flat base for bolting down to the framework. A collar is forged in one with the spindle to receive the face of the saw, which is prevented from turning by a stump key, or by a pin standing out from the face of the

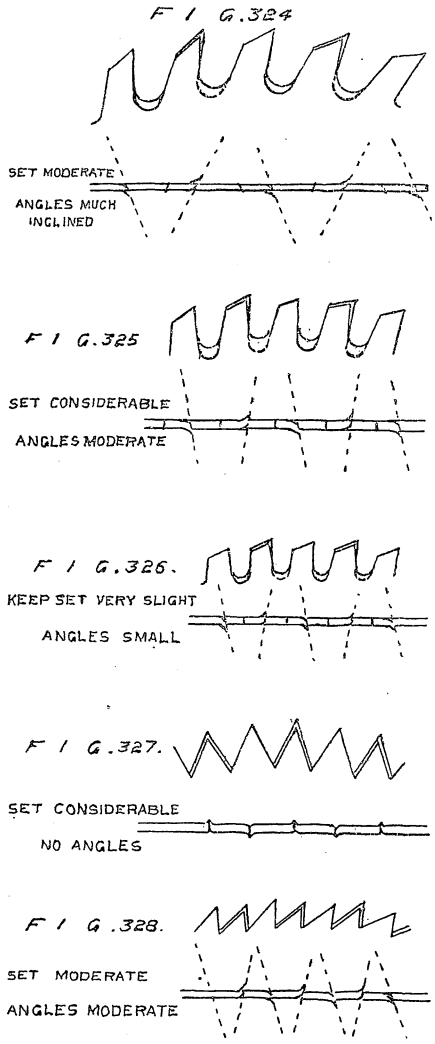
collar, and fitting a keyway or a hole in the saw plate. A similar collar or washer bored to slide over the spindle outside the saw acts as a clamp, being pinched in place with a screwed nut or nuts. At the opposite end a fast and loose pulley are attached, the one next the bench—that is, the fast one—being provided with a flange to retain the belt. These spindles ready fitted are sold in various sizes by the makers of wood-working machinery, or they can be made with little trouble.

The shapes of the teeth of circular saws should properly vary with the nature of the work which they have to do, though it would be, of course, much too inconvenient to change saws so often as different qualities of timber or different directions of the grain required cutting. Yet it is well, where much work is being done, to have three or four saws in the shop, and to replace one with another when the quantity of one sort of cutting is sufficient to compensate for the trouble of changing. I have shown five different types of teeth, the first (Fig. 324) for ripping soft wood, the second (Fig. 325) for cross-cutting the same, the third (Fig. 326) for sawing hard wood with, or across the grain, the fourth (Fig. 327) a cross-cut saw pure and simple, suitable for hard or for soft wood, the quantity of set alone varying; the fifth (Fig. 328) a small circular of from 4 to 8in. diameter. In the Fig. 324 the teeth are large and deep, have much rake, and a moderate amount of set. In Fig. 325 they are smaller, and have somewhat less rake, but more set. In Fig. 326 they are smaller still, have still less rake, and very little set. In Fig. 327 the teeth are triangular, and the angles of the face and back may be equal, or the face may have a trifle less inclination than the back, thus approximating to the shape of Fig. 328, which is used indiscriminately on all thin stuff. If the third or fourth examples are used on soft wood they will not cut so quickly, nor remove the sawdust properly, and in wet or resinous wood will become rapidly heated. The first, if used for hard wood, will not cut sweetly, but show a tendency to hitch and make a loud chattering or ringing noise, and probably heat and become buckled if forced to its work, and also sag and show deep grooves. I am, of course, speaking of extreme cases, since it is very often the practice to set and sharpen a saw in a medium fashion and use that indiscriminately for all jobbing work, hence I have presented these chiefly as typical forms to enable the reader the better to understand the principles to be observed in the sharpening of saw teeth. Practical sawyers know that within certain moderate limits, variations in the shapes and angles of saw teeth may be permitted without appearing to affect the capability of the saw. I have sometimes been surprised at the saw mills to find that in the cutting up of even the largest logs the very same saw is used for both hard and soft woods, so that at one moment a log of oak has been cut, and at the next a log of resinous pitch pine has been put on, and then again a piece of cross-cutting has been effected, and with no difference apparently in the readiness with which the tasks were performed. But this does not invalidate by any means the theory that rake and set and pitch should properly vary. The reason why the work is performed so satisfactorily is that the saws in mills are kept in perfect order, both as to set and pitch; they are also well packed, and any buckle in them is promptly hammered out, and last, but not least, they are power driven. Again, it is frequently customary with those who do make a difference in their saws to depend less on rake than on the angle of sharpening, the face of the teeth for soft wood being much more inclined than for hard wood (see Figs. 324, 326), so that while in the first case a point or corner only of the tooth cuts at first, in the latter the thickness, or nearly the whole tooth thickness, is presented at once. One thing in which most men inexperienced in the use of saws will blunder is in giving too much set to the teeth, forgetting that the minimum of set, given with *exact regularity*, is far preferable in any case to a larger amount imparted irregularly. So that the main points to be attended to are the giving of that precise amount of set, and no more, which will enable the plate to clear in the wood, the stoning of the saw to make it truly circular, so that each single tooth shall do its work, none standing above the others, and the sharpening of each tooth point to the same precise angle with the rest, whatever that angle may be; and to these we may add the preservation of the depths of the gullets with as near an approach to uniformity as possible, since on these depends the proper clearance of the sawdust.

Since the sweetness of working of the saws depends mainly on their sharpening and setting, a note or two thereon will not be amiss. The sharpening of the gulleted saws is done by means of a mill saw file, which is flat on the two faces, and rounding in section on the edges. The saw being first topped by running it in place against a piece of hard stone, the teeth are filed from alternate sides, the whole

of the alternate teeth being done from one side first of all, when the saw is reversed in the vice, and the filing of the other alternate set effected. The average angles may be gathered from the diagrams. Frequently the gulleting is done with a separate round parallel file, and only the faces and backs of the teeth with the mill saw file. The gullets should not be allowed to diminish in depth, and in order to lessen the labour of preserving them intact, it is well to have an emery wheel of the proper section for gulleting; then one application of the wheel will deepen the teeth sufficiently to allow of three or four successive sharpenings of the fronts and backs alone, and by this means the labour of gulleting with the file can be avoided. The setting is variously done with a setting block (Fig. 329) held in the vice, and

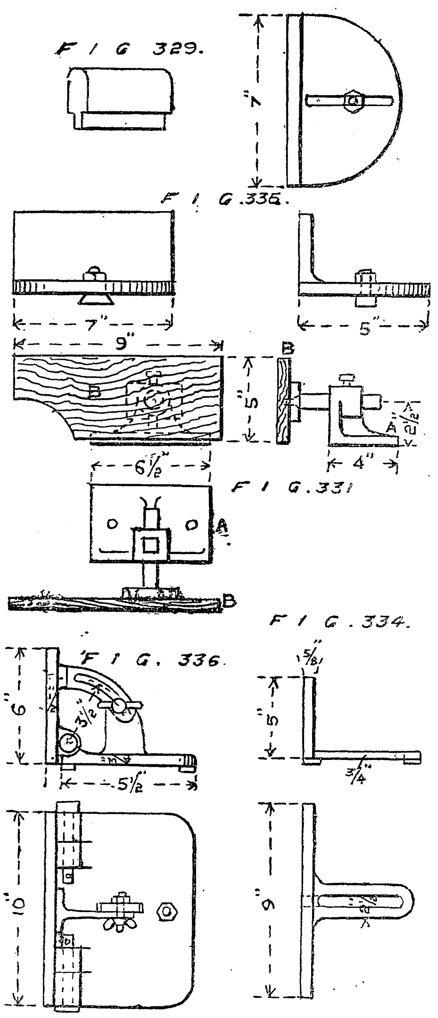


across which the saw is laid at the constant angle required, the teeth being struck with the set hammer; or by means of the common notched saw set, or by means of one of the numerous set-pliers of English or American manufacture.

It is usual and necessary to pack all but the smallest saws with oiled tow or gasket, to prevent them from becoming overheated, and at the same time to generate by the friction of the gasket just that moderate degree of warmth which, being equably diffused through the saw, shall prevent local heating, and consequent tension, which produces vibration or wabbling motion and unpleasant metallic ring. The ringing sound is due to the circumferential portion of the plate expanding more than the central parts, and producing a temporary buckle. The tow is kept in place by a slip of hard wood, mahogany being best, fastened on the bottom of the table on each side of the saw at the front or cutting portion, a rebate or recess being made to take the oiled tow.

A portion of the table must be made loose, for the removal and replacement of the saw on its spindle. To provide for this I have made that part of the table immediately in front of the saw plate loosely fitting upon the cross-bars, on which it is held by common wood screws (Fig. 330). That portion of the table on the opposite face of the saw is made of a corresponding piece in order that, as the saw widens the slit in time by its friction, both sides of the slit may be renewed easily. It is almost needless to say that the slips should be made of some good hard-grained wood, as mahogany, beech, birch, or oak.

It would be instructive to examine the different types of fences or guides used in conjunction with the circular saw bench. One objection to a wooden bench is that it is not readily adaptable to the superior sort of guides; nevertheless, with a little extra trouble, useful guides can be rigged up thereon, both for parallel and angular sawing. About the simplest fence which can be employed is that shown in Fig. 331, in which the bracket A is

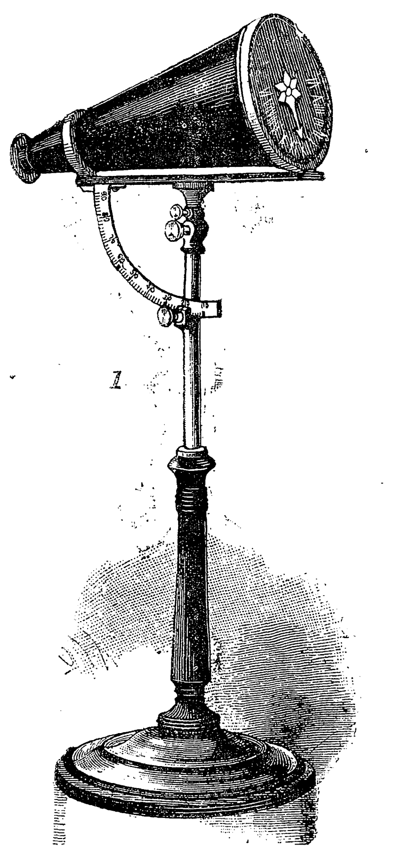


bolted down to the table in one uniform position by means of two coach screws, which are readily removable when the table is wanted clear, while the actual guide itself, B, is slid to and fro by means of the long turned pin moving in the bored hole in the boss of the bracket, and set in any position by the pinching screw. This is for parallel cutting simply.

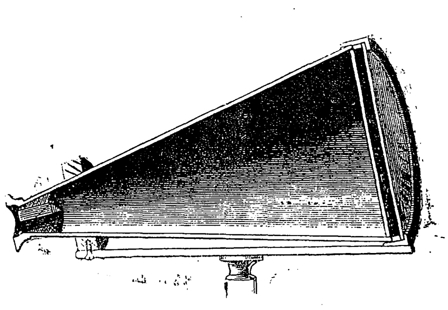
But if we want to rig up something more readily adjustable and truer, we must adopt some other mode of guidance, and the most convenient method in this case is to have a groove or grooves cut in the table. But easily working grooves, and strong enough to resist the strain of a bolt, and the tendency to fray out or become jagged at the edges, are not to be obtained in wood. Hence metal must be introduced. Without, however, making the entire table of metal, there are simple and effective devices which can be adopted. One such is shown in Fig. 332, by which it is seen that the table is grooved across to a certain distance, and two strips of brass or of wrought iron are let in flush, overlapping the groove, to receive the pull of a T-headed bolt. In the other (Fig. 333), a narrow plate of cast iron is sunk into the table, having a groove planed in it for a bolt. In each case also joggles or guide pieces are cast on the under sides of the fences to slide closely in the grooves. Three fences adapted to these grooves and to this particular bench are shown in the remaining figures. All are of cast iron. Fig. 334 is for parallel work simply, Fig. 335 is for turning round to any angle, the face remaining perpendicular. A simple form of fence to angle in the other direction while remaining parallel with the saw plate is drawn in Fig. 336.

PRACTICAL APPLICATIONS OF THE POLARISCOPE.

THE practical applications of the polariscope are few but important. In chemistry, its most prominent use is in the determination of sugars. In medicine, it finds an application in the examination of diabetic urine. In geology and mineralogy, it is of utility in determining the



origin and nature of rocks and minerals. In photometry, it forms the basis of several photometers. In photography, the polariscope, or at least a part of it—the nicol prism—has been employed for reducing the glare of highly illuminated objects. In a similar way, the nicol prism has been used for extending the field of vision in a fog. It forms an important part of the water telescope. It has also been used to some advantage in viewing paintings unfavourably situated in galleries. In the trades,

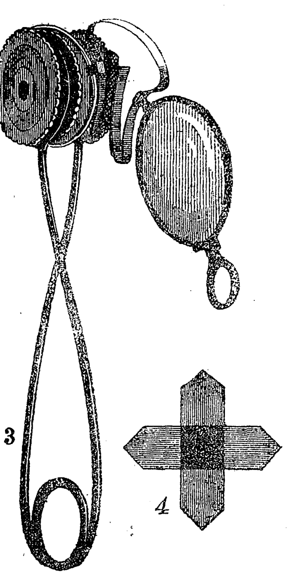


the polariscope has proved useful in detecting strains in glass. By opticians it has for years been recognised as a test for the genuineness of Brazilian pebble lenses for spectacles. It has also proved of great utility to the microscopist in the microscopic examination of structures.

One of the most curious uses of polarised light is the indication of the time of day. Sir Charles Wheatstone devised a polar clock in which a Nicol

* By G. M. HOPKINS, in the *Scientific American.*

prism in connection with atmospheric polarisation is made to indicate the time of day. Several forms of this instrument have been made; one of them is shown in Figs. 1 and 2. Atmospheric polarisation, according to Prof. Tyndall, is due to the



reflection of light from the fine particles of matter floating in the air. By examining the sky on a clear day by means of a Nicol prism and a plate of selenite or other crystal, polarisation will be detected without difficulty. The brightest effects are noticed at a point 90° from the sun. By directing a Nicol prism to the north pole of the heavens—a position always at right angles to the sun, or approximately so—and turning it round, the colours of the crystal plate, viewed through the prism, will change in a definite order, or, if the position of the Nicol be fixed, the movement of the sun will produce similar changes of colour. The polar clock is based upon this principle.

The inventor describes this instrument as follows: "At the extremity of a vertical pillar is fixed, within a brass ring, a glass disc, so inclined that its plane is perpendicular to the polar axis of the earth. On the lower half of this disc is a graduated semicircle, divided into twelve parts (each of which is again subdivided into five or ten parts), and against the divisions the hours of the day are marked, commencing and terminating with VI. Within the fixed brass ring containing the glass dial plate, the broad end of a conical tube is so fitted that it freely moves round it own axis; this broad end is closed by another glass disc, in the centre of which is a small star or other figure formed of thin films of selenite, exhibiting, when examined with polarised light, strongly contrasted colours; and a hand is painted in such a position as to be a prolongation of one of the principal sections of the crystalline films. At the smaller end of the conical tube a nicol prism is fixed so that either of its diagonals shall be 45° from the principal section of the selenite films. The instrument being so fixed that the axis of the conical tube shall coincide with the polar axis of the earth, and the eye of the observer being placed to the Nicol prism, it will be remarked that the selenite star will in general be richly coloured; but as the tube is turned on its axis the colours will vary in intensity, and in two positions will entirely disappear. In one of these positions, a smaller circular disc in the centre of the star will be a certain colour (red for instance), while in the other position it will exhibit the complementary colour. This effect is obtained by placing the principal section of the small central disc 22½° from that of the other films of selenite which form the star. The rule to ascertain the time by this instrument is as follows: The tube must be turned round by the hand of the observer until the coloured star entirely disappears, while the disc in the centre remains red; the hand will then point accurately to the hour. The accuracy with which the solar time may be indicated by this means will depend on the exactness with which the plane of polarisation can be determined. One degree of change in the plane corresponds with four minutes of solar time."

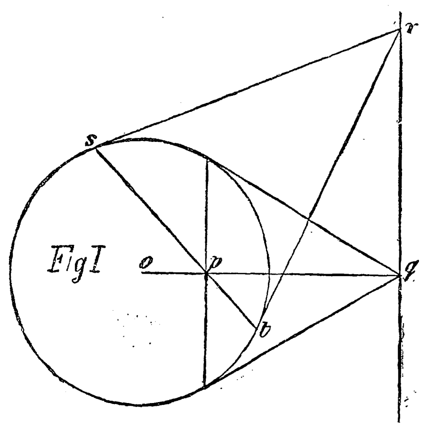
In Fig. 3 is shown the tourmalin tongs, the simplest polariscope known. It consists of two plates of tourmalin, cut parallel to the optic axis of the crystal, and mounted in cells arranged to turn in eyes formed at the extremities of the looped wire. When the plates are parallel light passes through them; but when they are arranged at right angles with each other the light is completely extinguished. If a plate of crystal, a Brazilian pebble spectacle lens for example, be placed between the tourmalins arranged in this way, the light will again pass, showing that it has been depolarised by the rock crystal.

This has been accepted an an infallible test of the genuineness of lenses of this class. In the hands of an expert it is undoubtedly valuable, but glass lenses may be put under strain by heating them and allowing them to cool rather quickly. They will then, to some degree, act on the polarised beam like the true crystal. This form of polariscope is useful in the examination of crystals generally, but on account of the natural dark colour of the tourmalin the utility of the instrument is limited.

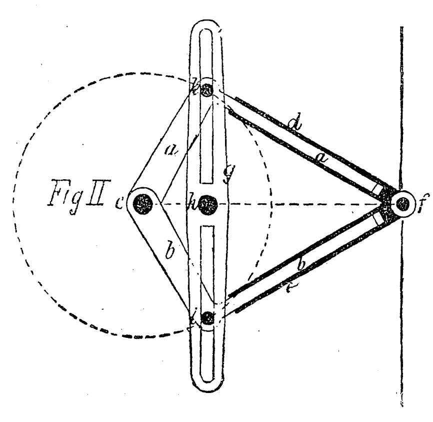
A polariscope designed for the examination of large objects, such as glassware, &c., consists of a bundle of 16 glass glates, about 20in or 24in. square, arranged with reference to the nicol prism employed as an analyser at an angle of 35° 25′. Behind the series of plates is hinged a board covered with black velvet, which may be raised up parallel with the glass plates when it is desired to polarise the beam by reflection. The analyser, a Nicol prism, is mounted in a revolvable tube, supported by a small adjustable standard. Articles to be examined are placed on a table between the polariser and analyser. The light for the polariscope should be taken through either a white paper or cloth screen or a plate of ground glass. Any strain in the article examined will exhibit itself by its depolarising effect on the polarised beam.

CONVERTING CIRCULAR INTO RECTILINEAR MOTION.*

Mechanism for converting circular into rectilinear motion is suggested by the following geometrical construction: Let a point p (Fig. 1) be assumed anywhere within the circumference of a circle. Join the centre o with p by a straight line, and produce it beyond the circumference. On

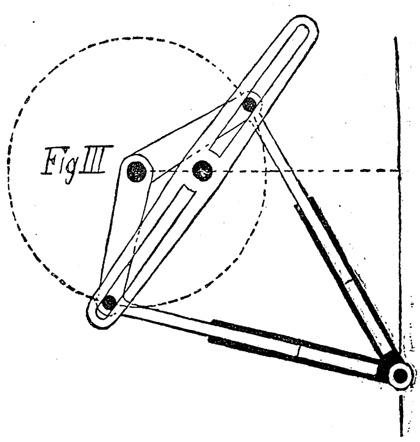


this line lay off a distance $o\,q$ so that the radius of the circle will be a mean proportional to $o\,p$ and $o\,q$. Through q draw $q\,r$ perpendicular to $o\,q$; $q\,r$, the polar of p, is the locus of the intersection of tangents to the circle drawn from the extremities of any chord passing through p. Thus, if we draw a chord $s\,p\,t$, and construct the tangents $s\,r$ and $t\,r$,



they will intersect at r somewhere in the straight line $q\,r$.

The proposed mechanism is shown at Fig. II. Two arms $a\,a$ and $b\,b$, on a common centre c, free to move independently of each other, are fitted with sleeves d and e, which are jointed by the pin f. If now we add a slotted link g, which moves freely around the centre h controlling the positions of the pins k and l, it will be seen that since the pins k, h, and l are always in the same straight line,



the locus of the centre of the pin f will, according to Fig. 1, be a straight line.

Fig. III. shows the mechanism in another position. The above geometrical construction is clearly explained in Prof. Newcomb's "Analytic Geometry." See section: Synthetic Geometry of the Circle, p. 94.

* By F. R. Honey, Instructor in the Sheffield Scientific School, New Haven, Conn.

BITTERS IN DIGESTION.

If any doubt still survived as to the prejudicial action of bitters on the digestive process, Dr. Tschelzoff's recent experiments may be regarded as having given it the *coup de grâce*. He has shown that bitter substances produce effects more hurtful than beneficial on digestion and assimilation, though till quite recently it was an article of popular, if not of professional, belief that these substances, while proving indifferent in the peptonification of albumen, yet hindered fermentation, and were, therefore, useful in certain ailments of the stomach. Experimenting with a great number of bitter substances, chiefly extracts, as being in more general consumption, he dealt with artificial digestion prepared with gastric juice; and in other cases he administered flesh to dogs, to some of which he gave bitter extracts, and, having sacrificed the animals, he weighed the quantity of the meat digested. In still other cases he kept the dogs alive while introducing into their stomachs, through permanent fistulæ, either flesh only, or flesh in union with bitters. He found invariably that in artificial digestion a small amount of bitter extract suffices to retard the digestion of fresh fibrine, and that the same effect, rather less pronounced, is produced in the natural stomach. Turning next to determine in what way bitters can whet the appetite, whether by augmenting the gastric secretion or by irritation of the mucuous membrane, he experimented on dogs in whose stomachs he had made permanent fistulæ. After having introduced flesh only or flesh in union with bitters, he collected the gastric juice, and found that, in these cases also, the bitter extracts diminished the gastric secretion, which underwent only a slight and brief augmentation when the bitters were employed in small doses. In every case the energy of the gastric juice was enfeebled. As a further result of experiment, he ascertained that bitters retarded the pancreatic digestion, while the biliary secretion was enhanced by extracts of absinthe and trefoil. The traditional belief, or rather assumption, that bitter extracts retard fermentation, is further shown by Tschelzoff to be fallacious. Indeed, the stronger the dose of bitters, the greater the intensity of the fermentation; in this case, however, the bitters do not behave in the same manner, and so the extracts of quassia and absinthe do not ferment, while fermentation becomes stronger in presence of powdered rhubarb or quinine. Finally, the putrefaction of organic substances, like blood or urine, he found to be favoured by the presence of bitter extracts, which in the organism also impede the assimilation of nitrogenised compounds.—*Lancet.*

A new central railway station, said to be the largest in the world, is nearing completion at Frankfort-on-the-Main. It has taken six years to construct, and will cost about £150,000, of which the Government has contributed about £100,000 and the Ludwig Railway Company the balance.

The plans for the Paris 1889 Exhibition have been approved. The main building will cover 230,000 square mètres, or 30,000 more than were occupied in 1878.

SCIENTIFIC SOCIETIES.

WESTERN MICROSCOPICAL CLUB.

On Monday week this club met at the house of Mr. Francis P. Pascoe, F.L.S., of Burlington-road, Bayswater. The host gave a *résumé* of what is known in regard to the peculiar crustaceans known as Pycnogons, to which collectors in marine zoology attach some importance. Until 1881 but little was known of these animals. In that year Dr. Anton Dohrn and Dr. Hoek published two very important works. These authors considered the Pycnogonida to form a distinct class of the Arthropoda. In old times they were referred to the Arachnida; Linnæus even placed the few species known to him in the genus Phalangium. In later times they were referred by Johnston, Kroyer, and Milne-Edwards to the Crustacea. Now they are generally classed again with the Arachnida, between the mites and the spiders. Häckel divided the Arachnida into the true and the false, the latter comprising the Pycnogonida and the Arctisca (water bears); he has since, however, referred the latter to the worms. Mr. Pascoe inclines to the view that they are neither crab nor spider forms, but he is unwilling to place them in a sort of no man's land. He has in his "Zoological Classification" included them in the crustacea. They certainly possess eight ambulatory legs, as do spiders, and have a similar arrangement of the eyes; other characteristics appear to approximate them more closely to the Crustacea. Huxley's suggestion that their proboscis is formed, as in the mites, by the coalesced representatives of the Cheliceræ and Pedipalpi is shown by Hoek to be untenable. Of the eight legs which are the main argument to prove that they are Arachnida, the first pair, as well as an accessory pair between them, are attached to a special or independent segment, and this is held to disprove their Arachnidan affinity. The absence of a respiratory apparatus is also a condition of many Crustacea, in which, it must be recollected, the variations of structure are of far higher morphological importance than in the other classes of Arthropoda. And so in the Pycnogonida we find many of them without eyes, some without mandibles and without palpi, the accessory legs sometimes absent in the female—the male only carrying the eggs, and the embryo either resembling the larva of the Copepoda in having three pairs of appendages round the mouth (the ambulatory legs being a subsequent outgrowth from the body), or the young animal when it leaves its larval envelope is already provided with them. The most striking character of the Pycnogonida is the small size of the body, it being in some cases only about one-sixth the length, and even thinner, than one of the legs; the abdomen is reduced to a mere peg-like tubercule. Of the four thoracic segments the anterior is sometimes suturally marked off from the head, but according to Johnston, Savigny has proved that the so-called proboscis is the head, that part behind the proboscis belongs to the thorax, to which the palpi are attached, and, consequently, the latter are only modified legs, which, with the ovigerous legs, would give seven pair, or three more than any Arachnidan. In consequence of the smallness of the body the internal organs are almost entirely placed in the legs, the stomach sending very long cæca into them, and the heart also branching out into them. The eggs formed in the legs are emitted through small openings at their base. The eye is the only organ of sense, but it is frequently absent or rudimentary; when present they are two or four in number, and although simple they have an analogy with the compound eye. The nervous system consists of a brain and four or five ganglia. There are not many known species. We have about thirty, a few being found under stones in tidal pools, but the majority in the open sea. In the *Challenger* expedition, over a course of 69,000 miles, there occurred only thirty-six species—one dredged at 38 fathoms had no eyes, while another at 1,875 fathoms had "two extraordinary large kidney-shaped eyes directed forwards, and two, very small, backwards." From 2,160 to 2,650 fathoms—a trifle over three miles—the eyes in all were rudimentary. Like all long-legged invertebrates they are very sluggish. It is hard to say what they feed on, apparently not vegetable matter. As to size they vary considerably, some are comparatively minute, the largest known (Collossendeis gigas) has legs nearly 12in. long and a body less than 2in. It is doubtful if any are parasitic.

Mr. A. W. Stokes, F.C.S., of Vestry Hall, Paddington, was unanimously re-elected hon. secretary. Any information as to the club may be obtained from him.

No record is kept of the yield in the United States in cubic feet of natural gas. The amount of coal displaced by gas in 1885 was 3,161,600 tons, valued at 4,854,200 dols. In 1884 the coal displaced was valued at 1,460,000 dols. The yield has increased tenfold since 1883.

SCIENTIFIC NEWS.

The elements of Comet Barnard have been computed from observations made at Königsberg, Vienna, and Palermo, by Dr. H. Oppenheim, of Vienna. T = 1886 Dec. 23·5706 Berlin M.T.; $\pi - \Omega$ 79° 44′ 24″; Ω 140° 5′ 53″; i 93° 54′ 7″ mean equinox 1886; log. q 9·90350. Ephemeris for Berlin midnight reads:

	R.A.			N. Dec.	
Nov. 12	12h.	29m.	14s.	10°	8·0′
14	12	38	41	10	55·5
16	12	48	45	11	45·2

Three more minor planets have been recently discovered, thus bringing the total number to 261. The first was discovered by Dr. Peters, of Clinton, New York, on Nov. 1, the position being R.A. 1h. 40m., N.P.D. 85° 30′ 47″; daily motion minus 3m. 36s., plus 4′. The other two were discovered by Dr. Palisa, of Vienna, on Nov. 4. The position of the first was R.A. 2h. 18m. 52s., N.P.D. 75° 57′ 43″, moving slowly N.; of the second, R.A. 2h. 17m. 58s., N.P.D. 76° 13′ 25″ daily motion, minus 3½m., plus 3′.

Part 1, Vol. V. of the *Journal* of the Liverpool Astronomical Society contains a variety of papers on astronomical subjects which will interest its readers, notes, reviews, and correspondence. "The Moon Surveyed in Common Telescopes," by T. G. Elger, is a paper which will be of use to many tiros.

The French Government has granted the funds required for the completion of the observatory of Algiers, which will be in full operation by next spring. Two assistants have been sent to join M. Trépied, and two more are to be selected from the pupils of the School of Astronomy this winter.

The Paris Academy of Sciences propose that an International Conference shall be held in Paris next spring, and make arrangements for a photographic map of the heavens to be simultaneously executed by ten or more observatories in different parts of the globe.

The permanent Committee of the International Geodetic Conference includes Prof. Hirsch, of the Neuchâtel Observatory (sec.), Prof. Förster (Prussia), Sande (Holland), Faye (France), Ferrero (Italy), Ibannez (Spain), Ragel (Saxony), Oppolzer (Austria), Stepnicki (Russia), and Zachariae (Denmark). The next Conference will be held in 1887 at Nice, on the invitation of M. Bischoffsheim, owner of the great Observatory there. Before separating, the Conference passed a resolution requesting the Prussian Government to invite other States to join the International Geodetic Society.

The following is the list of names to be submitted to the Fellows of the Royal Society at the forthcoming anniversary meeting (Nov. 30) for election as the Council for the ensuing session: President, Prof. G. G. Stokes, M.A., D.C.L., L.L.D.; treasurer, J. Evans, D.C.L., LL.D.; secretaries, Prof. M. Foster, M.A., M.D., and Lord Rayleigh, M.A., D.C.L.; foreign secretary, Prof. A. W. Williamson, LL.D.; other members of the Council, Prof. Robert B. Clifton, M.A., Prof. G. H. Darwin, M.A., L.L.D., W. T. Thiselton Dyer, M.A., Prof. D. Ferrier, M.A., E. Frankland, D.C.L., A. Gamgee, M.D., A. Geikie, LL.D., Prof. J. H. Gilbert, M.A., J. Hopkinson, M.A., D.Sc., J. N. Lockyer, F.R.A.S., Sir Lyon Playfair, K.C.B., LL.D., Prof. Bartholomew Price, M.A., Prof. Pritchard, M.A., Admiral Sir G. H. Richards, K.C.B., Prof. Arthur Schüster, Ph.D., and P. L. Sclater, M.A.

The death is announced of William Wakeling Boreham, of Haverhill, Essex, for forty-one years a Fellow of the Royal Astronomical Society. Mr. Boreham was in his 83rd year.

There are signs that at last something will be done about the Gresham lectures; but it is to be hoped that the Mercers' Company will not adopt the suggestion to utilise the funds for the encouragement of students destined for commercial careers, in order that they may acquire a useful knowledge of modern languages. If the Gresham committee do not know how to make the lectures provided for under the will of Sir Thos. Gresham popular and attractive they should resign, or hand over the funds to the Finsbury Technical College. The Gresham lecturer on Astronomy has done his best to attract audiences, and has been fairly successful; but he has been handicapped by the time of delivery being fixed at an hour which is just a little too early for the majority of the young people engaged in the City.

The president of the Geologists' Association, Mr. W. Topley, delivered his address on the erosion of the Coasts of England and Wales last Friday, in the course of which he stated that it was probable the total area of dry land in this country is not less than it was 500 years ago, and may be much more; but although the waste from erosion is not so great as was at one time suspected, there is abundant evidence that the avoidable loss is much greater than it need be, if proper control were exercised, either by the Board of Trade, or by some other board possessing the requisite powers. Some parts of the coast suffer by the removal of shingle from the beach by the action of the sea, which is compensated for—probably more than compensated for—by the filling up of shallow bays and estuaries; but it would be better to prevent the erosion, if possible, for that sometimes involves the ruin of valuable property. The British Association, it will be remembered, has a committee whose duty it is to report on this question, and Mr. Topley is secretary to that committee.

At the meeting of the Edinburgh Geological Society last week, Mr. Ralph Richardson, vice-president, delivered an address on the antiquity of man, in which he pointed out that there was a paucity of "finds" of fossil mammalia in Scotland as compared with those discovered in England, and stated that some of the polished implements of the savage Papuans of to-day resembled those of primeval man which had been found fossilised in Scotland.

Mr. Miles Settle, of the Darcy Lever Collieries, near Bolton, recently exhibited his electric safety-lamp and water cartridge to a number of visitors interested in mining. The "Settle" is an incandescent electric lamp attached to a float suspended to a glass globe and surrounded with water. Fracture of the glass breaks the connection, and the lamp goes out. The lamp is asserted to be perfectly safe, excepting from wilful injury. It was shown of two sizes, large for main roads, powder magazines, &c., and portable, of the weight and size of an ordinary miner's lamp, with a much brighter light. The experiments were successful in firing the water cartridge without flame when placed amid coal dust and gunpowder, and also in breaking the lamp without exploding the gas with which it was surrounded.

We are informed that the success which has attended Professor Silvanus Thompson's lectures on "Electric Bells" at the Finsbury Technical College, is such that the course will be repeated next autumn. The next course of "special lectures" by Professor Thompson is on "Electro-deposition of Metals"—chiefly of nickel—and begins on November 18th. Laboratory instruction is provided to accompany the lectures. Another special course on "Solders and Soldering" will be begun on the same date by Mr. Millis.

It is stated that a factory for working Ramie fibre—the China grass plant (*Boehmeria nivea*)—has been recently established near Gerona by a French company. The plant was introduced to that part of Spain in 1870, and its cultivation having proved successful, three machines are now at work which decorticate nearly 1,000lb. a day, producing a fibre which is much cheaper, finer, and stronger than either jute or hemp, while the refuse can be used for paper making. So far as jute is concerned the statements may be true; but it is not easy to believe that the thread is finer and stronger than hemp.

While great efforts have been made—not without success—to develop the cultivation of cinchona trees in India and Ceylon, there has been an idea that other plants might be found which would be as useful as remedial agents, and it is now asserted that the leaves of a native Ceylon plant, *Michelia niligerica* possess marked antipyretic properties, a decoction of the plant acting, indeed, more powerfully than cinchona. A peculiar, bitter principle, is said to have been extracted from the leaves. Meantime, experiments have been made as to the effect of manure in increasing the yield of quinine from cinchona bark, and according to the Government quinologist at Madras the question is now settled, for comparative

tests show a gain of from 20 to 50 per cent. in favour of manured trees—the increased yield of the valuable alkaloid more than covering the cost of the manure and its application.

In a pamphlet recently issued by Mr. Marvin, entitled "The Coming Deluge of Petroleum," it is stated that there is an oil well in Baku which delivers 11,000 tons of petroleum per day—that is, from a single orifice, "10in. wide," there spouts more oil than from the whole of the wells of America, Galicia, Roumania, Burmah, &c.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents. The editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, *332, Strand, W.C.*

All Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

**** In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks, a vice from whence great inconveniences derive their original."—*Montaigne's Essays.*

SMALL STARS NEAR VEGA—31 M. ANDROMEDÆ.

[26470.]—WITH reference to the estimated values of the small stars near Vega, quoted by Mr. Sadler in his interesting letter (No. 26,441, page 214), it should be borne in mind that they are essentially atmospheric tests, and that any estimates of magnitude are the merest approximations, in consequence of the blaze of the large star. As a matter of fact, the field was examined on some half-dozen nights without a trace of any other stars except A and B being seen, and some of the smaller ones were only visible with the greatest difficulty by using a high power and small field to exclude the light of Vega as far as possible. The fainter stars were only seen on one night.

Regarding the reported change in 31 M. Andromedæ referred to by Mr. I. W. Ward (letter 26455, p. 217), I find from my notes the Nebula was observed on Sept. 15 and 28 without any change being noticed, again on Oct. 19, when the central part appeared bright, but the air was too thick to render the observation of much value, and again on the 5th inst., after the moon had set, when no trace of any star or bright point (other than the usual nucleus) could be detected, and the central condensation did not seem brighter than usual.

I have several times noted apparent fluctuations in the light of the central portion; but it must always be a matter of grave doubt how far atmospheric conditions are responsible for these. I am not aware what aperture was used in the Continental observations recorded in the *Astronomische Nachrichten*, but there is nothing within the grasp of my 10in. reflector.

Kenneth J. Tarrant.

Letchford House, Pinner, Nov. 6.

A SUGGESTION IN STELLAR CHROMATICS.

[26471.]—SOME little time back Mr. Francis Galton suggested in the pages of a contemporary that Roman mosaic was probably the best material for preserving a scale of colours for use by anthropologists. Since I came across that suggestion it has occurred to me that, on account of its imperishable nature, a scale of colours in mosaic would be admirably adapted for use in ascertaining the colours of stars; for it is almost certain that any colour disc printed upon paper must undergo in the course of time a great change, due not only to the colour fading through the action of light and contact with the atmosphere, but also to the paper itself becoming darker by age.

Take, for example, the plate of colours in Admiral Smyth's "Sidereal Chromatics": the difficulty of distinguishing several of the discs from each other, particularly by artificial light (which the present writer and Mr. McCann called attention to in the *Astro. Register*, Vol. XIX.), is probably due, not so much to the colours not having been selected for viewing by lamp-light, but to the colours, especially the fainter ones, having undergone a change since they were printed.

As those interested in this subject are aware, from my previous communications *re* "star colours," I am not in favour of what I have elsewhere termed "the eye-and-memory method" of ascertaining the colour of a star; but until some instrumental means has been devised that will meet with the approval of the majority of astronomers, it is obviously our duty to perfect the present method as far as possible, and the first step to take is to get a standard series of colours. It being undoubtedly desirable that the subject of star colours should be placed upon a more satisfactory footing than it at present holds, it is a pity some scientific body, such as the British Association, for instance, does not take the matter up. What is wanted is a scale of colours selected with reference to certain portions of the spectrum, the colours, when chosen, to be imitated and preserved in some imperishable material, such as mosaic, and a suitable nomenclature for the same.

B. J. Hopkins.

ORGAN WINDCHESTS.

[26472.]—I AM delighted to find your obliging correspondents, Mr. Audsley and "Uranium," are again writing on this very interesting subject. I would ask the favour of their opinion on the windchests illustrated on pages 414, 525, and 597, Vol. XXXII., ENGLISH MECHANIC, as regards their suitability for chamber-organ purposes. They appear an admirable invention in one or two respects, doing away with the "slider" and its attendant danger of leakage of the wind; and the ventil system for admitting wind to separate registers is introduced in a simple manner. I fear, however, that the touch at the keys would be heavy, and perhaps the pipes would not speak readily.

Mr. Landel should, by all means, have three or four stops entirely of wood in his organ, especially if it is in a dry place. There is a roundness of tone consequent on the employment of wood, and low pressure of wind obtainable by no other means.

Guernsey. **C. H. D.**

GRINDING AND POLISHING GLASS SPECULA.

[26473.]—I HAD hoped before this to have given a description of a following altazimuth stand; but I have been hindered, and as Mr. Wigmore's letter (26005) has been so long unanswered, it now demands priority of attention. I still adhere to what I said in letter 25317—viz., that it would not "be fair to the trade to give in public a description of the work of any living maker without his consent," simply because perfection is not often to be found, and if I were to take the worst specimens of anyone's work, I could speak ill of it. The fact is, each maker excels in certain points, and is liable to a slip as well as anyone else, and of the four English makers now before the public—Mr. With, Mr. Calver, Mr. Linscott, and Mr. Jones—each has produced good specula. I am upon very friendly terms with them all, and wish to remain so. If I can do any of them good, I will. I wish to do neither of them any harm. At the same time I constantly keep in view the duty I have to perform to the large number of users of the telescope, and to the science of astronomy as far as it can be aided by improving the telescope, and I have every reason to believe that I have improved the character of specula even in the trade, and that this improvement will be more felt in years to come than just now. This I have done by calling attention to certain defects and their remedy, publicly and privately, and these are gradually being eliminated, and I hope will ultimately disappear. It would be very ungracious, yea very unfair of me, to blaze abroad defects of makers, when no one professes to be perfect. This might answer a selfish motive in me if I were a public maker, or intended to become one. I desire the position of a helper of all without mentioning names, and that for their sakes and the telescope's, for I believe the reflecting telescope has never had justice done to it yet. There are defects that have never had proper attention, but which I hope one by one to call attention to, which defects have been marring the finer definition of the reflector. I would just observe that these defects do not occur in all specula of any particular maker—each maker can boast of specula that are perfect, at least practically so. While upon this subject I may just state that since my last letter I have had two interviews with Mr. With, and very pleasant times we had together. Talking over the whole range of speculum-making, he very kindly volunteered to describe the whole of his process, telling me to ask any questions I liked as he proceeded, only saying that he could trust me not to make any improper use of the information to his or anyone else's injury who may be concerned. I should, therefore, not think of making public any of his processes, or anything that he told me that specially belonged to his process. Therefore no further questions need be asked me about what I know of Mr. With's process. I hope he will see his way clear, and I think he will ultimately, to write a description of his process for the benefit of all, as full as he gave me verbally. He commenced with the rough grinding, went on to the polishing, then came the interesting part—his mode of figuring, and then his mode of testing. One thing I noticed particularly, and which he pointed out to me towards the last—viz., his thorough knowledge of flexure, and the careful means he adopted to avoid it, only corroborating my testings of his specula that they are singularly free from flexure, and flexure is a terrible enemy to the finer definition. He showed me his stock of specula which he is now selling at about half their original price through Mr. Browning, and which are his latest and best productions.

And now as to the work of these makers. I need not give the figures of the aberration for five or any other number of those that are said to perform well; but state generally that specula that are only three-quarters corrected are said to perform well, and those that are one quarter over-corrected are said to perform well. One person will say under-correction is best, and ask for it in his particular speculum; another thinks over-correction is best, and asks for it in his particular speculum. I often pity the makers. The sensible view of the matter corroborated by my own experiments is that the nearer we get to the parabolic figure, the better for definition; and here Mr. Jones, who makes for Horne, Thornthwaite, and Wood, has adopted a very good plan of supplying a table of the zonal aberrations of each speculum he supplies, and warrants them to be within 1-100in. of the figures, thus the purchaser has some guarantee that he can understand and feel sure about. If this were demanded it would lead to permanent improvement in the figure of all future makers, as they would have to come up to a certain standard before they could get a name. Mr. Jones I know, having had two very interesting interviews with him; he has described to me his process, which is very different to Mr. With's and Mr. Linscott's. I am very careful not to divulge any of the secrets of either to the other makers, but if I can help either in his particular line it is my pleasure to do so. I have tested specula of Mr. Jones's and of Mr. Linscott's that have been exceedingly near to the parabolic curve, quite within the limits of the possible error of testing—i.e., the 1-100in. which in the telescope would be only 1-400 in., which no one could detect. Mr. Wigmore wishes me to give the aberrations of specula that have been considered good. Now, this I need not do, but will illustrate the matter in figures of zonal aberration at centre of curvature of a 12in. speculum whose aberration for the No. 1 zone (outside zone) ought to be, say, ·12. I have found specula whose aberration has been as low as ·08, and all other numbers up to ·16 have been said to be good; but I have detected a difference in the definition of specula that have been one-third under-corrected from one exactly right, as well as in specula that have been one-third over-corrected, but when the departure from the proper aberration is only $\frac{1}{6}$—i.e., taking a 12in. speculum, whose aberration ought to be, say, ·12 as above; if the aberration is ·1 or ·14, then I cannot tell the difference, in the telescope, between it and one that is exactly ·12; so that I call a speculum practically perfect that is not more than $\frac{1}{6}$ wrong. I mean this only to apply to specula whose foci are about nine times their diameter. I hope this will meet Mr. Wigmore's wishes, as it is the result not of five, but of scores of testings and observations.

And now as to Mr. Wigmore's own speculum. It is regular in figure; this is an important achievement, and shows that his polish is all right, and that he only wants to carry the correction a little further, as he has not carried it as near as I should. I always try to get the correction to within $\frac{1}{100}$in. of the required amount. Now, all his polisher wanted was a little more, say, $\frac{1}{50}$in. cut off the outside facets, bringing it to nothing at the centre; then polish again till the polisher gets nearly dry, which would be perhaps twenty or thirty minutes. Then test—the correction would almost be bound to be nearer; if not exactly right, then take a little more off the outside, bringing it to nothing at the centre. I sometimes find that one half-hour's polishing or figuring, as it is called, does not exhaust the amount of correction that the last cutting of the facets will give: this I know when a rapid correction is going on from working to working; in that case I work another half-hour without altering the polisher, and the correction will probably be carried a little further, but not so much as before, showing that the correction for that form of polisher is exhausted, and will allow a little more graduation of the outside of the polisher coming off to nothing at the centre, if the proper correction has not been already reached; by this means we can always come within $\frac{1}{100}$in. of the calculated correction above or below, and this is near enough for all practical purposes. I always, after I have polished enough to get the surface sufficiently bright to test with certainty, begin to graduate my polisher

to the shape that produces the parabola, and thus I utilise the time of polishing in getting the proper shaped polisher, and generally many half hour's polishing before I have got all the emery marks out. I have got the parabola, which I keep pretty near to by testing after each half-hour's polishing, and altering my polisher if needed to bring up to the parabola, or reduce the correction if I have overstepped it, and thus I go on polishing out the emery marks till they are all gone, when I have the parabola to the $\frac{1}{100}$in.

I may give Mr. Wigmore and others the hint that I have been trying successfully a polisher with two square inch facets instead of one square inch facets, and putting them on the tool upon exactly the same principle—viz., the groove nearest the centre $\frac{1}{8}$th of two inches from the centre, i.e., $\frac{1}{4}$in., and the other groove that crosses this and is nearest to the centre I put $\frac{3}{4}$in. from the centre, filling up the polisher from these with the two inch facets. I cast my facets $\frac{3}{8}$in. thick to begin with, and cast upon Mr. Tweedale's plan, which is a great improvement; thus this polisher is easier made, there being only a quarter the number of facets to put on. But I find I have to make two small grooves at right-angles to one another on each facet, dividing each facet into four smaller ones. These grooves are about $\frac{1}{8}$in. wide and $\frac{1}{16}$in. deep; they prevent the suction of such large facets being too great—in fact, I cannot work without these cross grooves. This plan is a great saving of time and trouble. I hope to more fully describe this plan, with details of working, at some future time. I mention it here that all may take the hint at once.

I give below an extract from a letter I received from an amateur in New South Wales. He requested me to order for him a $12\frac{1}{2}$in. speculum from Chance Brothers and Co., thinking the order would receive more attention from me than from an unknown individual. Of course, I got the speculum for him, and got Chance Brothers to pack it and send it off. They say that they shall be happy to supply amateurs in any part of the world, with specula at the same rate and with the same care in packing, as they should for any regular maker, so that to trouble me about this matter is now unnecessary. They have a scale of charges which I consider very reasonable, and any inquiry will receive prompt attention. Their full address is "Chance Brothers and Co., Glass Works, near Birmingham."

I now give the extract that will interest all amateurs at home, knowing as they do that our amateur brothers in New South Wales have to get all their information from the ENGLISH MECHANIC. He says, after he has done with asking me to get a glass disc for him, that "in addition to which it is my great desire to convey to you my humble appreciation of your excellent directions as given from time to time in that most useful journal, the ENGLISH MECHANIC, instructions that have been in Sydney the means of setting several to work in earnest. One friend has completed mirrors up to 19in. diameter, with which aperture I have had some magnificent views of the planets and our great clusters, whilst half-second double stars are beautifully defined. Another amateur has finished four specula, the largest of 10in., which have proved satisfactory. Spurred on by the success of these gentlemen, although then in my teens, I managed to successfully finish a reflector of 7in. aperture, which is so interesting that I am anxious to try a larger size, and with that object in view, would trespass upon your kindness and ask you to procure the disc."

All this is very encouraging to us all, and especially so to me, who feels that if amateurs can make and accurately test by the shadow and zonal test their specula, this will lead to a steady improvement in the trade, and thus the mass of users of the telescope who cannot make their own telescopes, will have at their command, at convenient prices, improved instruments. Now, it is the shadow and zonal tests combined that reveal to us the real nature of the curve. Let every amateur, and all in the trade, too, remember that they must not divorce these two tests. The amateur is apt to think "Oh, if I can but get the zones to answer to the calculated values as described by Mr. Wassell, and thus get the parabola, I shall be all right, and shall be sure to have good definition." Yes, and those in the trade when first adopting the zonal test, are apt to think the same. Now, let me not disparage the zonal test. Anyone using it will be bound to get a near approach to the parabola, nearer than ever he got before, and all the rays will be brought to a focus nearer to one distance from the speculum, at the eyepiece when in the telescope, than before the use of the zonal test. So far, there will be a vast improvement. Now the zonal test helps us no further than this—viz., it most accurately enables us to detect longitudinal aberration. Now, before the adoption of the zonal test, this correction for longitudinal aberration was a matter of guess-work, proved by the fact that mirrors have been turned out as being perfect which were only half-corrected, while others had double the amount of correction they ought to have. Now the zonal test puts a stop to all this by pointing out the error at once. But this longitudinal aberration is not the only error that a speculum is liable to, for the rays from the various parts of a speculum ought, not only to cross in the same plane, but to cross in the same point in that plane. Now, this the zonal test will not tell us anything about. To illustrate what I mean, suppose the rays from a star are all brought to cross at the same distance from the speculum; but the rays from one part of the speculum are crossing on one side of the rays from another part of the speculum, but yet at the same distance from the speculum. Now, further suppose that these various foci from different parts of the speculum cover an area of a circle at the eyepiece of $\frac{1}{10}$in. diameter, now magnify this by the eyepiece, and what kind of an image of a star would the amateur get? Why, like Jupiter in a fog. Of course I know this is an exaggeration; but the principle I wish to explain is there—viz., that we must avoid lateral as well as longitudinal aberration.

Now, the shadow test deals with lateral aberration, and does not touch longitudinal aberration, while the zonal test deals with longitudinal aberration, and does not touch lateral. There are two insidious sources of error causing lateral aberration that require great care to avoid, and most careful and patient testing to detect. One I have already dealt with—viz., flexure. I am sorry to say I have not only detected this in amateur's work, but in good makers' work; some error in supporting while polishing is the cause. Let all look to this. The other cause of lateral aberration is a small waviness in the surface. This is very insidious. I will narrate one of my own experiences in testing to illustrate its insidiousness, and as a warning to testers as well as to workers. I had sent to me a speculum, that its present owner could not get to define well on a star. Its previous owner praised it much—had even written a testimonial that was printed, and upon this testimonial it was bought. I was rather interested to find out how this discrepancy of testimony arose: its present owner so described its performance on a star, that I saw he knew what he was writing about. I tested the speculum the first day it came to me, for I felt deeply interested. I found it about three-quarters- corrected by the zonal test, and there seemed to be no flexure; but much as I was puzzled at finding no more wrong, for I knew that the quarter under-correction would not account for the defects so well described by its owner, I did not there and then condemn its owner's judgment, for I never depend on a testing till after the speculum has been allowed to remain in the same atmosphere for many hours, so I waited till the next day, tested it again, with exactly similar results—i.e., with only about one-quarter-under-correction. I was now really puzzled, and could not get it off my mind all day. I began to think that there was something seriously wrong in its owner's mind, and that perhaps its first owner was right. I tested it again the next day, for I could not get this puzzle off my mind; but with the same result. I may add that I carefully tested it for flexure each day; but could find nothing to account for the defect. A time or two I thought I saw a little indication of flexure; but upon more careful scrutiny found it was only the mind perplexed grasping at a straw that I could not support the charge of flexure upon when more carefully examined. I now thought of writing to its owner, telling him he must have made some mistake, and that the speculum was a pretty good one, and that the only defect I could find was that it was not quite enough corrected, but that this would not account for its defect in the telescope; but I thought I would wait till the next day and think it over again—the fact was, I did not like to give it up. Well, the next day, I felt myself irresistibly drawn down the cellar again; with a kind of forlorn-hope feeling I lit my lamp and put my eye to the shutter, and began to pass it across the shadows with rays at different points, watching the shadows with a feeling of despair, when I thought I saw on one part of the speculum a mottled appearance; this gradually spread all over the surface. Is it possible, I said to myself, that the surface is uneven? I went to the speculum and wiped it carefully to make sure that the appearance was not caused by dew, or a kind of film that comes over glass surfaces that are left exposed to the open air; but still there were the small irregularities. This appearance I was well acquainted with in my early speculum working, but never expected to find it in a speculum of this maker. This blinded my perception before; but now this mottled appearance I could not get rid of, for every time I looked at the speculum, for days after, and until it went out of my possession, there they were easily to be seen, being an illustration of the well-known fact that what will easily escape observation till once seen will then become most easily seen. I was not prepared to find this defect in this maker's work, for I had often spoken of his work as free from this defect; yet here was a slip that accounted for the very defects complained of by its owner. I passed the speculum on to another who is very apt at testing, and told him to look for the mottled appearance, and he saw it at once, corroborating all my description of it. Now, this uneven surface would cause the rays reflected from the sides of the undulations to be scattered over a small area at the eyepiece, instead of being brought to a point. I have dwelt thus much on this experience of mine to impress upon all the importance of keeping in mind every possible error while testing, and testing carefully for each, and taking nothing for granted. Now, at the risk of making this letter too long, I think I ought to mention some of the principal causes of this unevenness of surface, which is so fatal to fine definition, and yet may exist on what is as a whole a parabolic surface, and will therefore pass the zonal testing. The cause of this unevenness of surface is unevenness of cut on the facets of the polisher; in other words, one part cutting more than another, and these, in their passage across the face of the speculum, making a number of irregular grooves, which, being crossed by the revolution of the speculum, and altered in their position by the revolution of the polisher, leave irregular hills and vales. If we apply rouge during the polishing it will increase the cut around the edges of the facets, where it can easily get, leaving the centres but poorly supplied, thus causing irregularity of cut on the face of the polisher, and irregular valleys on the face of the speculum. When the polisher has been used too long the rouge gets irregularly imbedded in the face of the pitch, and irregularity of cut ensues, with the mottled appearance under testing. When the pitch is too thin on the polisher, say from $\frac{1}{16}$in. downwards, the pitch cannot yield regularly, and the irregular resistance causes irregular cut. I find about $\frac{1}{4}$ to $\frac{1}{8}$ thick work very well; the thicker the pitch the more even the surface. I have been trying $\frac{3}{8}$ thick, and it works very well. A polisher that has been laid by for a week or two, and thus got out of shape, if used without allowing time for its forming itself to the shape of the speculum, will, of course, only cut in the high points of the facets, and thus cause the undulating surface, with its mottled appearance under testing. The above are some of the causes which have come under my own notice, and which I have noted, and are sufficient to put us on our guard against every cause of unequal cut in the polisher.

The shadow test when carefully used detects any irregularity in the surface, whether caused by flexure or undulations; therefore the shadow test ought never to be divorced from the zonal test in the examination of a speculum.

I wish to further add that in the future I do not undertake to test specula previous to their being purchased, and only purchased subject to my giving a good report. I will only undertake to test specula that have some peculiarity that cannot otherwise be explained, and the discovery of the cause of which may lead to some useful information or results. I am forced to this restriction because the number of specula sent to me to test has greatly increased and become a burden without leading to results that aid the improvement of the telescope. There comes a period in the history of us all when our labour and time are of more value than to be spent on mere routine work.

H. A. Wassell.

Addenbrook Villa, Love-lane, Stourbridge.

"HAS ENGLAND GONE UP-HILL OR DOWN DURING THE LAST FIFTY YEARS?"

[26474.]—My capitalistic opponents are evidently badly hurt. I have struck home. Only a blow that "made itself felt" could have produced three such ludicrous howls as the letters of "U., Birmingham," "H. G. E.," and "B. R." (26373-4-5, Oct. 15). As for the last-named, mine ancient enemy, he fairly evacuates his position, and leaves me master of the field. He is wise in his generation. Albeit, even his short note, emanating as it does from a member of the upper or the middle class (he does not deny the soft impeachment), could not be entirely free from misrepresentation. I did not say, as he asserts I did, that I believed "increased deposits [in savings banks] indicate greater poverty." What I did say, as anyone may see by referring to my letter, was that "as a rule, the darker, not the brighter, a man's *prospects* are [not his position] the more he saves"—a distinction and a difference.

"U., Birmingham," "rushes in" to the rescue of "B. R." just as the latter throws down his arms and flies. I sympathise with "U., Birmingham," in the unfortunate predicament in which "B. R." leaves him. I am also sorry to disillusionise "U., Birmingham." He evidently takes the flattering unction to his soul that he makes a good point when he says that Socialists, believing it to be "unfair to accept dividends," would "only invest in concerns which would be unable to declare

them." Now, "would 'U.' be surprised to hear" that Socialists, in the case given, regarding *interest* and *plunder* as interchangeable terms, would, voluntarily, *not invest at all?* "How goes the game now?" I am sadly afraid "U." has the laugh against him, which, I need not add, I mournfully deplore. But he has the consolation of knowing he provoked it himself.

I am glad to learn from this correspondent that some of the tramway companies of his town have "lately reduced the hours of working to twelve per diem." So "late," evidently, has this been done, that few outside "U.'s" native place have as yet heard of it. That the reform has been effected at all may be placed to the credit of the wholesome lessons Socialists are teaching the community. From 16 hours to 12 per day is a reduction, certainly; and it shows what even tramway shareholders will sacrifice out of their plundered hoard to stave off for an hour longer the evil "day of reckoning" with the awakened workers. But this reduction, let it be understood, is anything but enough. Another will have to be made—this time to 8 hours or less. And what about wages under this precious Brummagem plan? Are they reduced too? "U." says, "The men receive a fair remuneration." Pray, what is meant by "fair"? "Fair" happens to be a relative term, and a very elastic one into the bargain. It may mean anything between eighteen and eighty shillings per week, just according to the ideas of fairness held by the person using it. "U.'s" idea of fairness and cognate matters may be inferred from his remark concerning the practice of certain other victims of capitalist greed, which practice I described as "pawning their Sunday coats and petticoats on Monday and redeeming them again on Saturday." This "U." is "fair" enough to say is "in many cases caused rather from bad management than extreme poverty." "Bad management"! How can their management be either good or bad when they have (so to speak) nothing to manage? "Bad management," forsooth! One would like to witness the superior management with which "U." would keep himself, a wife, and family, pay rack-rent and frequent doctor's bills, and be out of employment about three months or more of the twelve—all with the wages received by those who are compelled to resort to such practices as the one described, said wages ranging from sixteen to eighteen shillings per week. "Bad management, indeed! When will these impudent capitalistic libellers, whose luxury is purchased at the price of the producers' misery, cease to insult as well as injure? Not, I am more and more afraid every day, until the terrible upheaval of a bloody revolution shall wrest from their grasp their power to do either. They are apparently as incapable of learning from the past as they are of preparing for the future. Like the Church of Rome, they "learn nothing": but, unlike it, they forget everything. They are sowing—what? They are drifting—whither?

"H. G. E." is the next to take up the cudgels on behalf of "B. R." In "replying" to me he talks as capitalists and their apologists usually do—in the words of Artemus Ward, "with an imagination untrammelled by the slightest knowledge of the subject." He confesses his inability to make "head or tail" of the paragraph in my letter on the Savings Bank question. "Open confession is good for the soul." It is also, in this case, good for me, as well as for the soul of the confessary—if he has one. It is always as well to know the sort of opponent with whom you have to deal. It may, e.g., prevent your being guilty of that regrettable blunder crystallised into the saying *re* "throwing pearls." I admit, now, that I have been so guilty. But my guilt, I hope, is venial, for I sinned in ignorance. I was unaware of the retarded mental condition of "H. G. E." I did not know that he was incapable of estimating at its proper value the trite truism expressed in the formula: $2 \times 2 = 4$. I am sorry he is unable to perceive that if the deposits in the Post Office Savings Bank since 1861 have averaged about £2 14s. 8d. each, while in 1885 they only amounted to £2 6s. 5d., the corollary is that a decrease is shown of 8s. 3d. per deposit. I regret he fails to comprehend the statement that the total amount of the deficiency thus shown amounted last year to £2,670,000. I condole with him on his inability to draw from this the deduction that the assertion about deposits increasing in all savings banks is false, and that, on the contrary, they are materially decreasing. I lament these things, I say. At the same time, whether he can grasp them or not, there are the facts.

From bad "H. G. E." goes to worse. He asserts that I "talk of the 'real worker' as if the man who puts on an apron and stands at a bench is the only being who does any work." I would mildly venture to hint, and in the gentlest way imaginable, that this is a deliberate—well, misapprehension. Socialists are for ever iterating and reiterating that they include all who truly labour, no matter how, in the term "workers"; and what, in my letter, I did say, was the "real '*people*,' the workers." Who, however, out of Bedlam, expects fair play from capitalists and their hacks? Certainly not Socialists. We expect misrepresentation, and misrepresentation we get with a vengeance. The only characteristic exceptionable about "H. G. E.'s" experiment at the business is its extraordinary comparative insignificance. I am not surprised that he deliberately misrepresents—I am astounded that he deliberately misrepresents so little. There is, doubtless, every excuse for his leniency, though. This is probably his first try at the game. He is, as yet, merely a tyro at it, and is only just "getting his hand in." Judging from his present effort, however, I anticipate great things from him in this direction. I will even dare to prophesy in the matter. All uninured as he is to the fashionable pastime of baiting Socialists, he has already, in addition to shining in the small performance I have mentioned, unearthed the fact that Socialists, to adopt his own classic phraseology, "want to reverse things, so that they can occupy the places of employers and capitalists; and they are prepared to go any length to achieve the object, even to driving the capital [*sic*] out of the country" (!!) Yes, certainly "H. G. E." has a brilliant future before him. Practice makes perfect. In a very short time, if he continues his present rate of progress, he may reasonably be expected to discover that Socialists also yearn continually day and night to capture the Flying Devil of Fleet-street, and to run off with the Monument!

"H. G. E." next objects to the two examples I brought forward to prove that the condition of the English workers has not been ameliorated all round. He apparently did not trouble to read the letter which I attacked. In that letter the assertion was made that "*all classes* . . . . are better paid for labour, and work shorter hours." "*All* classes," observe! Could any statement contain less ambiguity? And yet I am accused of irrelevancy because I named as examples *two* classes, at random, out of *all!* And those two, moreover, by no means the worst! Why, I might have instanced, among a score of others, the matchbox makers, slaving all day and nearly all night for 2½d. per gross! Perhaps my opponents can discern some improvement, as regards hours and remuneration, in the condition of *this* specimen "class"! Really, there is no pleasing these capitalistic cavillers. They only pretend to show fight at all because they find themselves driven like rats into a corner. The factitious and fatuous objections I have indicated will serve to show the uninitiated and the unsophisticated to what desperate expedients the upholders of the present capitalist want of system have to resort in order to find any answer whatever to the unanswerable arguments Socialists hurl against them.

It is fortunate for "H. G. E." and "B. R." that my space in these columns is not unrestricted. I could go on exposing their fallacies and absurdities almost indefinitely. For the present, one more point must suffice. "H. G. E." heroically undertakes to show "how worthless are my facts." "One example," he bravely prefaces, will be sufficient (*sic*). What is the example? He tells us he finds that "B. R.'s" figures relating to population in 1871 and 1881 "include Ireland." Well? With all due deference to "H. G. E.'s" superior information as to what my letter contained, I was not aware that I disputed the accuracy of this statement. On the contrary, I was under the impression that I assumed the statistics on the subject of population to include all four divisions of the British Isles; and, what is more, I admitted their accuracy. What I objected to, and what neither "B. R." nor "H. G. E." has a word to say in defence of, was the "lumping together" by "B. R." of the figures relating to Ireland with those of England, Scotland, and Wales, and then his crowing over the fact that an increase was still shown. In that increase, I contended, Ireland did not participate. "H. G. E." endorses my contention, and proceeds to prove that not only did Ireland's population not increase during, for instance, 1871-81, but that it really *decreased*. Furthermore, he actually quotes figures, and puts the decrease during that time at "about 240,000"! Where, now, does the point of the "so much for Socialistic facts" remark come in? Out of his own mouth is he judged. Certes, when these capitalists and their hacks do venture into print in support of their preposterous claims, they make our task of refutation *too* easy.

In addition, however, to all this, "H. G. E." wilfully evades the real issue. I referred to the decrease in the population of Ireland "*during the last few years*." "H. G. E." disputes the accuracy of my general estimate, and gives me the figures, not for the "last few years," but for "1871-81": It must be as difficult for "H. G. E." to understand correct English as it is for him to write it. What, pray, have the figures quoted to do with the "last few years"? What have they to do with the point I raised. And how do they injuriously affect my contention? I have to inform "H. G. E.," as he appears ignorant of the fact, that we are living, not in 1881, but in 1886, and that, therefore, except to the fervid imagination possessed by himself, it is somewhat hard to suppose the phrase "last few years" implies the period "1871-81." The terrible years for the Irish people which immediately preceded and followed 1880, and which saw evictions alone at the rate of *one thousand per week*, are the years to which I referred. During the fearful winters and redemptionless summers of the years I name, those two effective clearing agencies, starvation and emigration—euphemisms for the rack-renting landlord and the speculating colonial capitalist—between them managed to slay or deport unnumbered thousands of one of the noblest races that ever inhabited this globe. Unnumbered, did I say? Unnumbered, perhaps, in the cold-blooded official statistics among which "H. G. E." grubs and gropes; but I at least am content to believe that the All-Father who numbers the very hairs of the heads of His children, will not see thus dealt with, impunibly, the lives of the innocent, the helpless, and the wronged. **A Socialist.**

POLARISATION OF LIGHT—BATTERIES—THE OPTICAL LANTERN—SILVERING GLASS.

[26475.]—It is much to be wished that Mr. W. G. Penny would make his exact meaning more clear by some elementary diagrams, without which I cannot be sure that I really understand him. And it is also to be desired that he would make himself absolutely sure of his facts and statements. As it is (and with the saving clause above) it appears to me that he is very seriously wrong in the facts and statements upon which he bases his conclusions. It is at least certain that some of his statements are gravely in error, and he appears also to have overlooked the fact that Professor Stokes and other mathematicians *have* taken into consideration the existence of vibrations in the ether in the longitudinal direction of the ray, as possibly or probably affecting certain phenomena.

There is a cardinal error in the very first paragraph of letter 26466; for the angle of polarisation is *not* that at which the loss of light in either reflection or refraction is "the greatest possible." It is simply the angle at which all the *reflected* light is perfectly polarised, and at which this quantity of reflected polarised light, and of the quantity of transmitted or refracted light *which is polarised*, are equal. The angle at which the "loss of brightness" is greatest is a perpendicular incidence for reflected light, and an incidence grazing the surface for refracted light.

Secondly, in these cases of reflection and refraction, it is a cardinal error to speak at all of brightness being "destroyed" as though it had vanished. It is nothing of the kind. Excepting the very small quantity *absorbed* by the medium—say, glass—or lost by scattered dispersion owing to imperfect polish, no "brightness" is "destroyed" at all. The incident light is simply divided into two portions. What is not reflected is transmitted or refracted, and *vice-versâ*.

So much is certain, and I believe Mr. Penny to be equally wrong in what follows; but not desiring to place any limits to discovery, await a diagram to explain precisely what he means. At present I will only say that, in my opinion, when by *any* possible polarising arrangement light is made incapable of passing the surface of a refracting substance, which really means (in other words) that it is *wholly reflected* therefrom, or wholly *absorbed therein* (as in a tourmaline) it is not "latent," and cannot be restored in any way. I do not possess a pair of prisms cut at the polarising angle; but I suspect Mr. Penny has been misled by some appearance he has not fully traced home to its real cause. Because I am certain of this one point at least: that the brightness he speaks of as "destroyed" is no such thing; it is simply, as regards all polarising arrangements depending on reflection and refraction (the case of a ray stopped by a crystal is somewhat different, but the principle still holds good) *gone somewhere else*. No one speaks or thinks of "non-existence" as he seems to suppose. I have made all the experiments I can think of with three plates of glass, which I suppose him to mean by "mirrors," and am so utterly unable to get any such effects as described that I await further explanation with some curiosity. At the same time, it is well to remark that *prisms* do sometimes produce phenomena apparently anomalous, till they have been properly investigated.

I have read "Cato's" letter on "A good Battery" (26463) with more than interest. Surely he does not need to be told, that if his statements are borne out by facts, there is a moderate fortune for him—sure. The battery he describes at the close—63 volts and 12½ ampères—it is hardly necessary to state, is amply sufficient to run an arc light of over 1,000 candles in an optical lantern. At present this requires 50 to 60 Grove or Bunsen cells at a cost of, say, 30s. per evening of three hours—that is what it really costs in practice. If he can *really* give for the same sum 126 hours, and it is not merely another battery puff, then, unless his battery is fearfully bulky, or expensive, or deleterious, or

dangerous to use, or has some other fatal defect, he has only to get it protected and put on the market, and customers must come in a rush for all sorts of purposes.

While on optical lanterns I may recall a short note in the spring, explaining the difficulty I had found in procuring limes to stand the powerful jets we now have without splitting across. I am glad to find that the well-known "Excelsior" limes sent out this season are from an entirely new source, and so far appear to stand all I have applied to them. I am told the lime is from a foreign quarry; anyway, it is very hard, fine in grain, and is turned beautifully, true as ever, with no signs of splintering out in cavities. As long as this supply may last I would wish for no better, and shall work with much greater comfort this winter.

Can any reader tell me the brightest burner I can get—either oil or gas—within about ⅝in. square as regards flame. I do not expect any *great* light, of course. I hope for perhaps 10 to 20 candles. There is no reason why I should not say that my real object is to get as bright a *simple* light as I can, *the size of a lime-spot* in the lantern, to work out without dazzling the course of the rays in some arrangements I have in hand.

Lastly, can any reader give me and others the formula for silvering glass *with a brush*. I know that small work is done this way—no trough work, but laid on with a brush like paint; and it would be a great convenience to be able to silver a small bit of micro-glass at pleasure. Or can the solution be bought anywhere?

Nov. 8. **Lewis Wright.**

EGYPTOLOGY.

[26476.]—THE point raised by "Memnon" (26418 and previous letters) respects the testimony of the Bible regarding dates, &c. He admits the value of its testimony; but puts it at "rough approximations." On my part, I contend that, while its testimony has some imperfections inseparable from human agency, it is of the very highest kind—not only equal, but greatly superior to all similar testimony which is regarded as sufficient to establish facts of the highest importance.

I adduced evidence sufficient to establish the authenticity of the Pentateuch. "Memnon" has not been quite fair to me here: he says, "The main defence offered by 'Ramases' is that of traditions of the Apostolic age." Now, I have given the earliest Jewish writings back to the days of Moses and earliest Jewish historians, which go back long before the Apostolic age, and are history, not tradition.

In the book of Joshua, for instance, the Law of Moses, the Book of the Law, which had been written and was to be read, is continually spoken of. In the first chapter the very words of Deuteronomy are twice quoted at length by Joshua. There are numerous other connecting links too numerous to mention here. The same holds good of the fragmentary Book of Judges, and of the history of Samuel, of the times and the writings of David and Solomon. And it has been shown that the architecture of Solomon's temple, notwithstanding its splendour and expanded proportions, shows itself, after the image of the tabernacle of the wilderness and Shiloh, to be only a tent no longer portable.

"Memnon" has no counter-testimony, either traditional or historical, to adduce, that Moses did not write the Pentateuch, and so he relies on objections as follows:—

1. Moses's date for the Deluge does not agree with that of Egyptian history. "Memnon" gives a number of authorities for dates, who base their opinions on Manetho and his reference to Menes. Of Manetho I may speak plainly. He pretended to derive his information from certain pillars in the Siraidic land, which had been inscribed in the secret dialect of Thoth before the Flood. Their contents translated into Greek were said to have been laid up in the Egyptian temples by the 2nd Thoth. Now the Greek language was unknown in Egypt at the time alleged. No classical historian condescended to notice this book.

The Christian author from whom we have the little that remains of it introduces Manetho as "a High Priest of the detestable Egyptian mysteries, and as great a liar as Berosus himself." Manetho obviously wrote with a view of astonishing the Greeks by an antiquity exceeding their own, and of which Herodotus, who preceded him, heard nothing from the earlier priests. Touching the dynasty of Menes, we have nothing save in the catalogue of Manetho's Monuments, it has none—its names are found only in the tradition of later days, and the escutcheon containing the name of Menes was the production not of his age, but of that of Ramases. An objection founded on such testimony as this, is worthless, especially as against the honest, straightforward testimony of the Bible.

2. The Scripture referred to by me (Deuteronomy xviii. 11), in reference to the life of the soul beyond death is in no sense doubtful. What could be plainer?

3. The omission of the names of the three Pharaohs is perfectly in harmony with archaic usages of writing. Anyhow, the objection is worth nothing, because it can very well consist with either view, and, therefore, proves or disproves neither.

4. This is a poor objection, and unworthy of "Memnon." The death and burial of a man like Moses would surely be recorded. Such a record would likely be added to his own writings, and before the days of putting a space even between words, it would naturally be joined on to his writings.

5. This objection is of no value, because it may harmonise with either view, and, therefore, proves or disproves neither. Copyists may have added to the margin of MS. a word or a sentence here and there, which afterwards was put into the text. These passages are not numerous. The jarring sects of the Jews, which held different views, forbade such. The one cited by "Memnon" is not one of them; in the original it is, "before the reigning of a king, to the sons of Israel." In the previous chapter a promise is made to Jacob that "kings should come out of his loins."

I am able to refer to Gesenius's words in a friend's Hebrew lexicon; like Memnon, I have no library to refer to, being at the seaside. Gesenius says, "*An age, a generation* of men, in the times of the patriarchs, was reckoned at a hundred years. See Genesis xv. 16, compare verse 13, and Exodus xii. 40. So among the Romans, the word *seculum* originally signified *age* or *generation* of men, and was later transferred." Rightly understood, they do not conflict with the Bible, or invalidate its testimony: to me they vastly support it.

Ramases.

[26477.]—I AM glad "E. L. G." (26446) agrees with me that the Pentateuch is *not* of Moses' age or by his hand. He thinks it is of the time of Saul, and probably by Samuel or his school. I consider that part of it is so; but not nearly all, and that the general editor was Ezra. "E. L. G." says it is a "single work"; but shortly after says it is compiled from older books. That it is a single work is flatly contradicted by itself, as can be easily seen by comparing Exodus vi. 3, where it is explicitly stated that God was not known by the name of Jehovah to Abraham, Isaac, and Jacob, with Genesis xiv. 25, and a multitude of other somewhat similar passages, where we find that word placed in the patriarchs' mouths. To be sure, the translators, with the usual clerical subtlety and daring, render the word Jehovah as "the Lord"; but, as "E. L. G." says about the age of the Pentateuch, "every decently-educated man" knows it is not so.

The ascription of the same story to Abram and Isaac, Gen. xii. and xxvi.; the order in Gen. vi. to take of every living flesh *two* into the ark, with Gen. vii., when all clean beasts are to be taken by *sevens;* the wet or first description of Creation, with the second or dry one; the generations of Adam in Gen. v., where Cain and Abel are omitted, with the previous statements, all bear out the fact that the book is a sort of mosaic, or patchwork, and *not* a single book; especially when one set of these stories are known to be by a writer who always uses the word Jehovah for God, and the other uses the word Elohim.

"E. L. G.'s" remark about Moses' Coptic is funny, as there is no proof he wrote a line for the Jews in that language. If he and the Jews spoke and used Coptic on leaving Egypt, that language would enter deeply into their later language; but notoriously it does not. The few instances that occur are explainable by the intercourse known to have existed in later times, the result of the immediate neighbourhood of the two peoples.

It is well known that the base of the Hebrew is *not* Egyptian; but, as the learned Mr. Sayce says, "The close resemblance between the Phœnico-Hebrew and Assyro-Babylonian languages proves that the speakers of them must have lived together for some time after their separation from the rest of their Semitic kindred." And, again: "The Hebrews themselves, if we may trust the evidence of language, physiognomy, and character, had the same ancestors as the Phœnicians, and at the time of the conquest of Canaan only differed from the people they expelled in being rude nomads instead of cultivated citizens." I am afraid the Coptic books written by Moses for the Jews only exist in the fertile imagination of "E. L. G."

That he is fanciful, arbitrary, and imaginative his letter proves most plainly; but his references to particular subjects are curiously inaccurate. Thus he says the Greek and Samaritan text adds the words, "*and their fathers*, which they had sojourned in Egypt and *Canaan* was 430 years" to Exodus xii. 40, and says the Hebrew Rabbis left them out and otherwise altered the text (the text that "Ramases" would so fully rely on) for some bad purpose. Possibly so; but who is to prove what the original text was? Perhaps the Greeks and Samaritans altered theirs. "E. L. G." has a grand proof that he is right, and refers to the prediction in Genesis xv. 13, which, as far as I can judge, *disproves* his assertions as far as it goes. It says: "And he said unto Abram, know of a surety that thy seed shall be a stranger in a land that is not theirs, and shall serve them, and they will afflict them four hundred years." This certainly does *not* prove they were to spend half the time comfortably in Canaan. Again, Isaac was directly ordered not to go to Egypt (Gen. xxvi.) and everything he could want was promised him. Yet, according to "E. L. G.," he must have been suffering sadly. The reference to Ishmael mocking Isaac is really comical, and the curious assertion that Abraham "set up" Hagar "as a Bedouin princess" is painfully opposed by the text, as is also his statement that the Jews had not (according to the Bible) 600,000 men "able to go forth to war." This is flatly contradicted by the text and by Numbers i. 46, and by Exodus xxxviii. 26, which says that the 603,500 men who were paid for were *above* 20 years of age, and *not* every soul above a month old, as "E. L. G." so fancifully asserts. Again, his reading of Joshua's miracle is plainly opposed to the text, which was always accepted till astronomers proved it to be wrong. In the revised version the translation is not at all like "E. L. G.'s," and we know it would soften it as much as possible.

I never said Manetho's assertions were fully to be relied on. We have no pure copy of his text; but all eminent Egyptologists place the accession of Menes before the date of the Flood, and I think the great antiquity of Egypt is better proved than the historical reliability of the Flood or its date.

Why "E. L. G." approves so much of the Hindoo, Chinese, and Babylonian records, and declines the Egyptian ones, I do not know, especially as the former claims an immense antiquity for that nation, and to them the date of the Flood would be nothing—indeed, they claim too much. I suppose "E. L. G." will fall back on the miserable plea that the Flood is not mythic, and was local. As the Bible says it covered the whole earth, and professes that Noah repeopled the world, I decline to admit any such loophole, or to alter the plain statements simply because they are ascertained to be wrong.

As Osiris plainly is a sun myth, it would be safer for "E. L. G." to assert (though equally wrongly) that Menes was Noah. If "E. L. G." will take up any one or two points I shall be glad to discuss them with him; but his present letter touches on so many points that it is not possible to deal with them all in a letter of reasonable length.

Memnon.

ANALYSIS OF SUGAR—SWEETNESS OF SUGAR OF DIFFERENT KINDS—DETECTION OF GRAPE SUGAR—ANALYSIS OF SILVER ALLOYS.

[26478.]—THE "Analysis of Sugar," so far as required by querist No. 60835, page 227, is not a very difficult matter. Certainly loaf-sugar ought to be wholly soluble in water—at least, when any reasonably small quantity, such as an ounce or two, is dissolved, and the residue should not have an appreciable weight. If any residue is left on dissolving the sample in cold water, "A.W.W." should filter it off, wash it thoroughly with cold water, and dry it at a gentle heat. On then boiling a portion with water, cooling the solution, and testing it with a solution of iodine, a blue coloration will be produced if starch be present. On igniting the remainder of the residue insoluble in water, any insoluble inorganic impurity will remain, and the querist's experience in inorganic analysis will enable him to ascertain its nature. For animal impurities generally it will be sufficient to ignite a weighed quantity of the sugar and weigh the ash. The complete combustion of sugar is difficult, and the ash is often light and easily blown away. Hence it is very desirable before igniting to moisten the powdered sugar slightly with water, and then add a little pure concentrated sulphuric acid. On heating the whole gently the mixture froths and subsequently forms a dry cinder. This is ignited at a dull red heat, and when the carbon is nearly burnt off the residue is again moistened with sulphuric acid and ignited till white. By this treatment the readily volatile, fusible, deliquescent potassium carbonate is converted into the less volatile and fusible potassium sulphate. A deduction of one-tenth is made from the weight obtained, as a correction for the increase due to the use of sulphuric acid.

The querist's statement that the sugar in question is not nearly so sweet as loaf-sugar usually is suggests that the sample is one of starch sugar or glucose. If so, he will find it will give a dark-brown coloration when boiled with a solution of caustic potash or soda. If he dissolves the sample in water, and adds a few drops of solution of naphtha of copper and sufficient caustic potash or soda to produce a clear, deep-blue solution, and then heats the liquid to boiling, little or no

change will result if he be dealing with genuine loaf-sugar; but an abundant yellow or red precipitate will be formed if glucose be present. In the latter case he will probably find the ash, and, perhaps, the residue insoluble in water, to consist chiefly of calcium sulphate. If, by the tests described, "A. W. W." concludes that glucose is present in quantity, while the sugar has the general appearance of ordinary loaf-sugar, I shall be glad if he will send me a specimen.

I may here remark that the statements made respecting the relative sweetness of different samples of sugar are often very misleading. They generally mean that, having tried two or more samples in succession by chewing a lump of each in the mouth, the observer concludes that the latter are the less sweet. But this conclusion may be vitiated by the partial insensibility to a sweet taste caused by the previously-tasted sample. It is similar to the necessity of adding more sugar to a cup of tea drunk after eating marmalade or honey. How often are we told that the sugar used in France is far let sweet than that employed in England; and the statement is generally capped by the assertion that the cause is that the former is made from beetroot and the latter from the sugar cane. This description of their origin is not very exact; but, even assuming it to be true, it is a fact that chemists are not able to recognise any difference between the pure crystallised sugar made from beetroot and that derived from the sugar-cane. In all their properties, both physical and chemical, they are generally regarded as absolutely identical; but occasionally the suggestion is made that a further investigation may establish differences. The sceptics prefer to speak of the two sugars as "beetose" and "cannose." Now, if there really be an essential difference in the sweetening power of the two products, it will go far in the indicated direction. My own impression is that the casual observer is deceived by the fact that the French sugar is commonly very porous, and hence a lump of given size does not weigh so much as an apparently equal one of a denser sugar. Hence the supposed inferior sweetening power. How often we are told that crystal sugar and sugar-candy are less sweet than powdered sugar and loaf-sugar, the fact being that they are all absolutely equal in sweetening power, and are convertible one into the other; but owing to the slow rate of solution of the denser forms they rarely have the opportunity of exercising their full effect on the palate. Crush all to powder, dissolve equal weights of each powder in similar measures of water, and employ equal measures of the solutions to sweeten your tea on consecutive evenings, avoiding a previous use of sweet edibles, and you will have a means of judging fairly of the relative sweetening powers of the specimens. It is an experiment nearly anyone can make, and if extended to glucose, levulose, beet sugar, glycerine, and other sweet bodies, and the results recorded, would be of considerable interest, and would confirm or refute the very questionable statements respecting relative degrees of sweetness which have too long been copied from one textbook to another.

The tests already given for glucose will suffice for the detection of "Grape Sugar" (unanswered query, No. 60278, page 588). The proportion present can be ascertained from the amount of copper reduced from the cupric to the cuprous state by a given weight of the sample. The process is known as Fehling's method, and is described in all books treating of sugar or of organic analysis. There are some other substances which also reduce alkaline cupric solutions, and hence the indication must not be relied on too absolutely.

The method given by the apparatus dealer to "G. E." (see letter 26419, p. 191) for the "Analysis of Silver Alloys" is perfectly good; but the querist does not seem to have sufficient knowledge of chemistry or chemical manipulation to make any analysis by him trustworthy. A little more knowledge would have told him that he ought not to evaporate the nitric acid so completely as to get a blue residue insoluble in water; and if on adding sodium carbonate he got a blue precipitate he should have added nitric acid cautiously, drop by drop, with stirring, till it was redissolved. I did not intend my statement that the "textbooks do not lay sufficient stress on the solubility of silver chloride in saline solutions" to be construed as a verification of the querist's conclusion that "small particles of silver chloride were dissolved by the hot nitrate of soda solution." On the contrary, I believe silver chloride to be absolutely insoluble in aqueous solutions of nitrates only, and in water containing any reasonable proportion of free nitric acid; but to be very sensibly soluble, on the other hand, in aqueous liquids containing metallic chlorides or free hydrochloric acid, even in very moderate quantity, and especially if hot; and to be not absolutely insoluble in pure water.

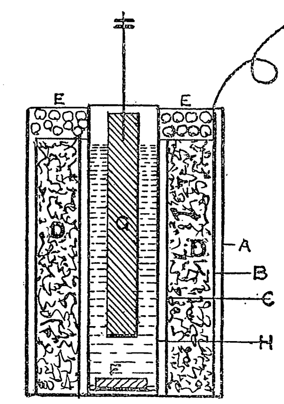
If "G. E." wishes to use the neutral process of determining silver, I should recommend him to put a definite quantity of standard salt solution into a white basin, and add a few drops of a strong solution of neutral potassium chromate. The neutralised solution is then dropped in from a burette, until the red colouration due to the formation of silver chromate ceases to disappear on stirring. If he then makes a precisely similar experiment with a solution of pure silver of the same strength as that of the sample, the relative amounts of the two solutions decolorised by equal measures of the salt solution will give the means of calculating the proportion of silver in the alloy. He can check the result by weighing the chloride of silver precipitated.

I did not intend my reference to the compilation of textbooks on chemistry to apply to Sutton's "Handbook of Volumetric Analysis." That work is decidedly the best on the subject, is in most cases thoroughly reliable, and is written by a practical analyst. If any statement made in it is not borne out by the experience of the querist, in all probability it is because the experience of "G. E." is deficient. Silver chloride should be collected on a paper filter, washed, dried, brushed from the filter into a porcelain crucible, and then heated till just fused. It may be removed from the crucible by means of strong ammonia; but the use of dilute sulphuric acid and a fragment of zinc is in some respects a preferable plan.

Sheffield, Nov. 8th. **Alfred H. Allen.**

THE DANIELL CELL FOR ELECTRIC LIGHTING — THE SCRAP COPPER CELL.

[26479.]—Having been very busy of late, I had quite overlooked "Nemo's" query (60523) *re* above. I should specify six 10-volt 5c.p. Woodhouse and Rawson lamps (I know these to be good from actual use), to be run up to about 7 or 8c.p. each. Although this shortens the life of the lamps, yet this is of secondary importance when such costly fuel as zinc furnishes the electrical energy to light them. These six would light the room very well; four would do it fairly. From experiments with the Daniell for large current, I should recommend "Nemo" to construct his cell according to the inclosed sketch, showing the cell in section.



A is the outer jar of well-glazed earthenware, 12in. high, 8in. in diameter. B, cylinder of very thin sheet copper, with a strip soldered to it for connection. C, another cylinder of sheet copper perforated. The space between B and C is filled with copper scrap. D, cuttings from sheet, &c., any shape, and packed closely to a height of 10in.; upon this is laid a sheet of copper, perforated, to hold the supply of crystals, E, of sulphate of copper, which must be replaced as they dissolve in the solution, which they will do in proportion to the amount of current passing. After the solution is saturated, these crystals do not dissolve when the battery is idle. F is the piece of zinc (unamalgamated) not in contact with G, to reduce any copper which comes through the porous pot H; this may be omitted if only a short run is required.

The solution of sulphate of copper in the outer cell should be about ½in. or so above the crystal shelf.

About fifteen cells would be required to light six lamps. The scrap copper can be bought at the price of old stuff—about 4d. per pound. The copper cylinders made of No. 30 B.W.G. copper sheet; this is ·012in. thick; it is made in sheets 24in. by 48in., weighing about 4lb. per sheet. The glazed outer cell can be dispensed with, and the copper cylinder itself made to take its place, with a bottom soldered in. Canvas porous cells can be used, but not so satisfactorily as the proper porous pots prepared according to my previous instructions—use 75 parts weight of paraffin wax, and 25 parts tallow. If "Nemo" requires any more information he may communicate privately with me—that is, if he wants prompt attention, and he decides to go on with this affair, especially as the dark nights are on us already.

I suppose the "wonderful" lamps are exploded. This is my experience with two—one called a 2½c.p., the other 5c.p. R. *cold*, of one (2½) 4·7 ohms, the other (5) 4·5 ohms. E.M.F. on lamp (on the ticket sent by makers) six volts. The R., hot, would be about one-half, or about 2·5 ohms, requiring, therefore, about 2·4 ampères. With this current they give a good light—probably 5c.p., not more; therefore, three watts per candle-power is the value of their efficiency. They are cheap and good, but certainly not "wonderful."

Middleton, Lancs. **F. L. Striffler.**

CALCIUM PYROBORATE.

[26480.]—I have been in communication with Col. Ross on the subject of Blowpipe Analysis, but he having gone abroad, and a letter I sent him, hoping that it would be forwarded, having been returned to me, I write to the "E.M.," hoping that the penetrative power of "our" paper may bring this to his notice.

This explanation will, I hope, relieve me from the charge of egotism, if I quote from a paper of mine on Calcium Borate which appeared in the *Chemical News* of October 22nd, and refer those interested to the paper itself.

It will there be seen that taking pure caustic lime or its carbonate as a starting point, and treating it with excess of boric oxide in a Fletcher's gas furnace, I obtained a fused glassy mass, which remained perfectly distinct from the surrounding boric oxide, and was of precisely similar appearance to the calcium borate balls obtained before the blowpipe.

Synthesis and analysis of this substance showed its composition to correspond closely with that of the calcium analogue of borax—i.e., CaB_4O_7. This body is fairly well known, and is also found native, hydrated and crystalline, in Peru; but its formation under the conditions described and its characteristic appearance I do not find mentioned. A possibility exists that the compound formed pyrologically may contain a larger proportion of boric oxide, for it is a characteristic of boric oxide to combine with bases in different proportions according to the relative quantities present and the temperature to which it is subjected. This is borne out by the observation that a large excess of boric oxide and prolonged heating had a tendency to form compounds containing less lime than is demanded by the formula CaB_4O_7, and coming nearer to the composition put forward by Col. Ross—viz., CaO 25 per cent. and B_2O_3 75 per cent.

B. B.

ORIGINAL ELECTRIC EXPERIMENTS — A NEW ARRANGEMENT OF ELECTRIC MACHINE.

[26481.]—In following out these experiments, I discovered what appears to me to be a new feature in frictional electrical machines. Thus, if we lay a piece of tinfoil upon a sheet of glass, and apply a rubber underneath the same, then, similarly to the manipulation of an electrophorus, if a finger be applied to the foil whilst the rubber is underneath it, much more electricity will be given off from the aforesaid foil upon the withdrawal of the rubber. This showed me that the ordinary disc electric, as seen in the shops, is wrongly constructed, there being a pair of rubbers opposite to each other at the opposite sides of the diameter of the disc. Now any rubber will only develop electricity proportionately to its area, and, as I have found, it possibly develops more, and that also in a greater state of tension, upon the opposite face of the glass to that upon which the friction is applied. Now, as electricity cannot be accumulated upon any rubber by continued rubbing beyond the quantity normal to its area, it follows that if one rubber be applied opposite to another, the electricity formed upon the opposite face escapes away through each cushion. In accordance with these considerations I have constructed the machine as figured, and it gives off a large quantity of electricity. It occurs to me that I may here state that, upon a careful study of the molecular theory, as explained in "Sigma's" (Mr. Sprague's) book upon electricity, it seems to meet the necessities of the case better than any other of which I am aware.

Fig. 1 is a back elevation; the disc is 26in. diameter, carefully selected, and only $\frac{1}{16}$in. full in thickness. The face was covered entirely with tinfoil pasted on, and to lay this on smoothly I used a rubber of flannel upon a piece of, say 6in. by 2½in., and kept wet whilst gently pressing out the superfluous paste; then, with a sharp-pointed knife and straight-edge, it was divided into 16 sectors divided from each other by ½in. spaces of glass, and when mounted *in situ* we must strike a circle of 5¾in. towards the centre of same, to insulate it from the boss upon the opposite side. This boss is made of two pieces of mahogany with grain reversed, and measures 3¾in. by 1in., and is affixed by means of the cement I have already mentioned in these pages, and could only be removed by smashing all in bits with a hammer. The spindle to which it

FIG. 1

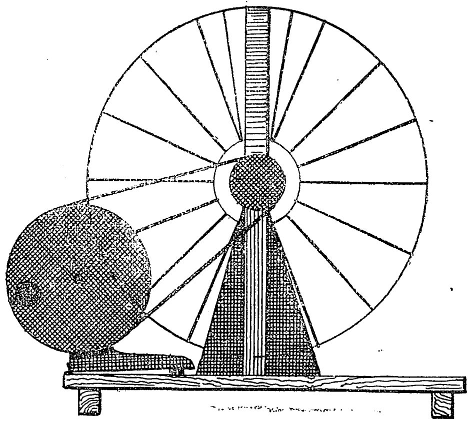


FIG. 2

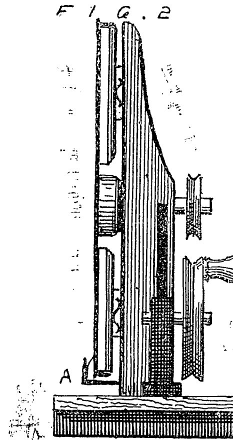

FIG. 3

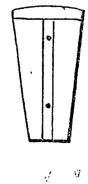

FIG. 4.

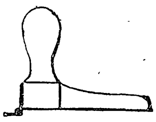


is attached by means of a brass faceplate and four woodscrews is a piece of brass tube ½in. diameter and 5¼in. long; this carries the mahogany driving-pulley, which is 3½in. by ¾in., and tightly fitted on same. This spindle fits accurately into a piece of iron gaspipe 4in. by ⅝in. rymered out and driven moderately tight into the standard at 15in. from the baseboard, which latter measures 29in. by 11in. by 1in., with two stiffening pieces, one under each end. The standard measures, including 1in. for mortice, 29½in. by 4in. by 1¼; it is better to divide the foot into two tenons, so as not to weaken the baseboard too much. In order to stiffen this against the strain of the band, it is well to glue and sprig on the two triangular pieces, as shown, say ½in. back from the edge of standard, and made out of ⅜in. timber. A shows the piece of small tube bent to a right-angle, one end tapped to screw into the standard, and having a couple of inches of the wire off a violin bass string fixed by a little peg, so as to touch each sector as it travels over the rubber. Fig. 3 shows the back of one of these. They are made of pine ¼in. thick, stiffened, as shown, by slips of, say, ¾in. square glued on to keep them flat. A piece of ordinary drugget is cut to same size, and kept in position by a piece of lining paper, which overlaps and is glued for, say, ½in. upon the back, which is in view. The tinfoil ought only to be cut and pasted so as to cover the front face, and not to communicate directly with the wood. Two French wire nails, with the heads cut off, form steady pins when driven into the standard to carry the cushion; and springs to keep them gently pressing the glass may be either of indiarubber, or thin sheet steel, such as that in the dresses of the ladies of the period. The glass can be slightly lubricated with ordinary paraffin oil as required, both to lessen friction, and to counteract the effects of a damp atmosphere. Fig. 4 is the piece of wood which carries the driving-wheel, being fixed to a well-made hinge, as shown, 2½in. long, so as to enable the band to be tightened by means of a wedge, and slackened when not in use. This measures 8½in. by 2in., and with its lever, 8½in. by ½in., and stud to carry driving-wheel, and this with a corresponding V-groove and handle, as well as a band of gut, or leather, or sash-line, completes the machine so far as experimental purposes require; but the framing may be ornamented, if so desired, to suit the requirements of the owner. It will be well to give all exposed glass upon the front face, say, two coats of shellac varnish, also all around the outside diameter and edge of the glass and tinfoil, but, of course, not upon the rubber side of same, nor under the foil sectors. The framing may have two coats of mahogany varnish, or else the shellac. I use a Leyden jar, or a conductor, as required, standing in front of the machine, each being provided with a piece of tubing with a single fine wire, as before mentioned, at each end, and curved so as to all but touch the sectors upon both sides of front face.

Nov. 5th. **A., Liverpool.**

GRAVITY.

[26482.]—THE question raised in this journal a few numbers back, respecting the behaviour of a body falling through a hole through the centre of the earth to the Antipodes branched off into some side issues, but was not satisfactorily answered. What shape the hole must be, or what course the body would take, may be left to be discussed. One correspondent affirmed that it would traverse the distance in about an hour, and would pass and repass the centre until it finally settled there. This is assuming that the rate of fall would increase in the same proportion as it does from above the earth to its surface, up to the centre, and then diminish in the same proportion, until it nearly reached the Antipodes. But that is just what requires proof. Is there any peculiar virtue, so to speak, in the centre? If the attraction which a body exercises is due to the sum of its parts, the matter nearest the falling body must exert the greatest influence, and that furthest from it the least. The centre then would be in the exact middle position, and the nearer the body approached it the less would be its velocity. This is assuming the density of the earth to be the same through its whole mass. Two pieces of cork floating in a glass of water will attract one another. Is the attraction due to the size of each or the weight? A pendulum vibrates at a certain rate on the surface of the earth. Is its rate due to its length or its weight? It is said to vibrate quicker in a deep mine. Is this because its weight is increased? Is its weight increased?

In the experiments that have been made has the question of the density of the surrounding strata been taken into consideration? Have the results always been identical? The theory has been lately advanced that the surface of the earth is solid up to a certain distance, then liquid, and then solid again of a much greater density. Does not this seem to bear its own refutation? If there be no weight at the centre there can be no specific gravity; the words have the same meaning. Is not matter that has the least specific gravity of a gaseous form, at least so far as we know? Would not the natural change be solid to liquid, liquid to gaseous, gaseous to what?—the ether that surrounds the world and fills space—if there be ether.

It has always been a subject of wonder that gravity has not more attracted the attention of science. Its law of attraction has seemed the only point of consideration. What is gravity? What is this wondrous force that molecules so small that human skill has never been able to isolate them, exert over each other? What is centripetal force that is always drawing the earth to the sun, and centrifugal force that is always resisting it? What is attraction of cohesion and attraction of repulsion? Is it chemical affinity, or motion, or supernatural force? Can it be increased and diminished at will? A core of soft iron with a certain current passing round it has its attraction increased, so that it attracts with more power certain substances. Can anything like it be done with other substances? The imagination may wander off into endless speculations as to the results that would follow could we neutralise the force of gravity in bodies, or increase it at will.

Has anything ever been attempted or done with gravity, save ascertaining the fact that it exists everywhere and in everything? **Angulus.**

THERMO-BATTERIES.

[26483.]—IN the *Minutes of Proceedings* of the Institute of Civil Engineers," issued July, 1886, there is an abstract of a paper by Wilhelm Penkert, on the "Transformation of Heat into Electrical Energy, and the cost of the latter in the case of Galvanic and Thermo-Batteries and Dynamo Machines," in which the following table is given as to the cost of 500 Watts per hour by the several methods mentioned:—

	Shillings.
Daniell's element	1·06
Bunsen element	1·51
Thermo-Batteries:—	
Rebeick's star form	5·65
Rebeick's straight form	7·17
Clamond's, heated by gas	16·03
Clamond's, heated by coal	0·42
Dynamo driven by steam	0·10
Dynamo driven by gas	0·25

From this it appears that Clamond's thermo-battery heated by coal is a very efficient and cheap source of electrical energy, and if it can be made cheaply, I should think it would make a good substitute for the dynamo and gas-engine for charging accumulators used in household electric lighting, and the current might also be used direct to drive motors.

In looking through my back numbers, I find that little has been said in "Ours" on the subject of thermo-batteries since 1876, when a letter appeared describing Clamond's battery heated by gas. The E.M.F. of the elements, which are sheet iron for the positive and an alloy of two parts of antimony and one of zinc for the negative metal, is stated to be $\frac{1}{20}$th of a volt with a difference of temperature of 200° Fahr. This, I think, must be a mistake, as, according to Dr. Stone's experiments (ENGLISH MECHANIC, Nov. 26, 1875), the E.M.F. of a pair composed of German silver and the antimony-zinc alloy was only the $\frac{1}{108}$th of a Daniell cell, with a difference of temperature of 80° C., and the iron and antimony-zinc couple has a less E.M.F. than that of the German silver and antimony-zinc couple just mentioned.

From the information that I have been able to get so far, it seems that 155 iron and antimony-zinc pairs would be required to give an E.M.F. of 1 volt, with a difference of temperature of 80° C.; and 44 bismuth and antimony pairs would not give more than 1 volt under the same circumstances, although Fleeming Jenkin (chap. 12, p. 183) speaks of a bismuth antimony pair being prepared "having, say, an E.M.F. of 100,000 micro-volts, or about $\frac{1}{10}$th the E.M.F. of a Daniell cell, while the resistance might be reduced to almost any desired extent by increasing the section of each element."

There must have been many improvements made in thermo-batteries within the last ten yeass, and letters on the subject from your scientific correspondents would, I am sure, be very instructive to many of us. An account of Clamond's improved thermo-battery, or of any new thermo-electric combinations and their comparative powers, would, I am sure, be most interesting.

I believe that it is only a question of time when thermo-batteries will take the place of all galvanic apparatus for the production of powerful currents at a constant potential. **J. G. H. B.**

A NEW (?) ELLIPSOGRAPH.

[26484.]—THAT the arrangement described in the ENGLISH MECHANIC of Oct. 22 produces a correct ellipse may be mathematically proved as follows:—

Referring to the figure already given, and considering each link as a rigid line, let $ad = bc = m$, and $ab = cd = n$. Join bd. Then in the triangles adb, dbc we have $ad = cb$, $ab = dc$, and bd common to both. The triangles are therefore equal, and the angle adb = angle dbc. Hence $ed = eb$, and therefore $ae + eb = ad = m$. The sum of the distance of the point e from two fixed points, a and b, being a constant quantity, it follows that the locus of e is an ellipse of which a and b are the foci. The major axis is m, and the minor axis $\sqrt{m^2 - n^2}$.

Charing, Kent. **J. R. Campbell.**

CHAMBER MUSIC AND MUSICAL INSTRUMENTS.

[26485.]—YOUR correspondent, "Musik Freund," will find a useful series of four papers on "How to Play Beethoven's Sonata's," by Lady Benedict, in the *Girl's Own Paper*, Vol. III.

After reading the fifth part of Mr. Audsley's notes on the chamber organ, it must be, I think, clear to all your musical readers that the chamber organ of the future will hold a very different position to that which it has held hitherto, and I, for one, am delighted that it should be so. Simply as a means of producing music, pipe against reed, argument on their respective merits is impossible, and were it even possible, would be ridiculous. It is simply for its marvellous power and beauty of expression and admirable adaptability in so many ways for home music in comparatively small and unpretentious homes that I place the Mustel organ so high, although, indeed, it is in place amid the highest art surroundings, and would be a worthy companion for such an instrument as Mr. Audsley describes. Gladly do I accept his invitation, conveyed through these columns, to see his organ, and I thank Mr. Editor for opening up to me such a vista of delight. I shall be glad to oblige our friend "Unanium" by giving to your readers the result of my visit, if you, Mr. Editor, care that I should do so. I hope that before many days are over Mr. Audsley will see my Mustel. I will ask him to give in your columns what he thinks concerning it. The views thereon of such an authority upon chamber music would, I think, be very acceptable to your readers, and must carry with them very great weight.

Country Solicitor.

MIDLAND EXPRESSES AND GRADIENTS.

[26486.]—SOME interesting accounts were given lately by "P." and "Kappa" of five runs with the Midland expresses. They have expressed surprise at the high speed of down trains between Radlett and St. Alban's, as the gradient is stated, in Mr. Foxwell's book, to be 1 in 176 up "past St.

Alban's." I think there is a slight misunderstanding here. I cannot lay my hands at this moment on the Midland section map, but, speaking from memory, I believe the ascent of 1 in 176 does not begin until about the 18th milepost, whence it passes St. Alban's to about the 23 m.p. It is succeeded by a fall of 1 in 200 for nearly three miles from Elstree summit, and it is down this bank that that high speed is generated which is gradually reduced while ascending the subsequent 1 in 176. A glance at the speed table given by your correspondents will show this very plainly, as after the 18th mile there is a prompt diminution of velocity.

I frequently timed the special at 65 miles an hour for two or three miles after Radlett, with down trains of twelve to fifteen coaches; and on one occasion, with No. 1567 and seven coaches, a speed of 70 miles was attained on the 16th mile.

"Kappa" quotes a good run with the 3.40 p.m. down train (engines 1477 and 1741, and 21 coaches); but, good as it was, there was nothing exceptional for that line. I have been in the 3.40 with 15 coaches and only one engine—No. 1478, the sister engine to the one which acted pilot in "Kappa's" trip—and the run from St. Pancras to Bedford (49¾ miles) was done in exactly one hour, the following length to Leicester occupying 63 minutes. The last three miles of the Sharnbrook bank were run up without a pilot, in five minutes, and the 17 miles from Leagrave to Bedford, stopping at the latter place, were descended in 16½ minutes, the highest speed being 73 miles an hour.

"Kappa" asks, "Is 75 miles an hour often done down the bank of 1 in 90 between Park Forest and Merfle, and if not, why not?" In my experience it is not often done, because of the curves, junctions, and necessity for being always prepared to slacken. When the trains are in good time, which I found to be generally the case, there is no need to run fast down-hill, and they go down at a steady pace of 50 or 55 miles an hour. When late I have known speeds of very nearly 75 miles an hour run down that branch; but this is quite exceptional.

Much has been said lately about the Midland, Leeds, and Scotch expresses losing time. I am able to say, from large experience, that time is very seldom, if ever, lost in the running, unless through slackening for signals. On the contrary, my experience has rather been that of your correspondents "P." and E. A. Speed, with Nos. 1337 and 1,741. I have known the 12.20 down make up nine minutes between Kentish Town and Nottingham. The conditional stop at Chesterfield often causes loss of time with the up trains, as they cannot run from Sheffield to Nottingham in 52 minutes, and stop at Chesterfield out of it.

The 1740 class engines have come out since I left England last year. Have they 19in. or 18in. cylinders? Both have been attributed to them in these columns. Also, what is their heating surface as compared with classes 1327, 1562, and 1667?

Charles Rous-Marten.

Wellington, N.Z., Sept. 22nd.

CARBONATE OF MANGANESE.

[26487.]—In reference to the paragraph in yours Nov. 5th, page 212, the discovery of this ore in North Wales is not of recent date. I have farmed large quantities of this same mineral from the same neighbourhood for fully ten years past, and am prepared to supply almost any quantity.

Geo. G. Blackwell.

BODY FALLING FROM A TRAIN IN MOTION.

[26488.]—Laying aside the resistance of the air (see letter 26448), the falling body will describe a parabola relatively to a fixed surface, or a straight vertical line relatively to a vertical plane carried by the train. Mr. Potts is confusing the fixed with the movable planes. **Glatton.**

ADJUSTABLE SPANNER.

[26489.]—Is this not an unnecessary complication of a well-known form of spanner—Bauer's patent? **H. S.**

An Ice Cavern.—It is reported from Vienna that a great ice cavern has been discovered on the southern slope of the Dachstein, or Schneeberg, the very conspicuous lofty mountain in Lower Austria which is visible from the ramparts of the capital. The general direction of the cavern runs from south to north, and it has been explored for a distance of 600 mètres, a sharp precipice seemingly 14 mètres deep having stopped for the time further progress. The cavern is from 5 to 6 mètres broad, and very lofty, giving the impression that the ice is enormously thick. The explorers are of opinion that a subterranean lake will be found in the cavern.

REPLIES TO QUERIES.

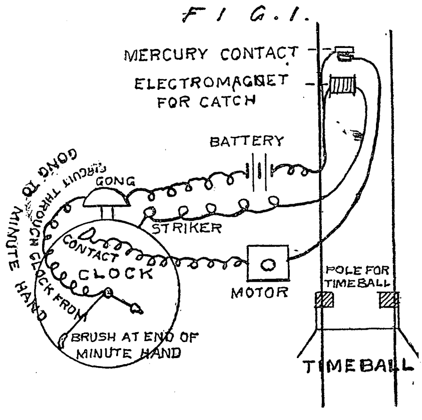
*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[60137.]—**Marking Ink.**—To Mr. Saml. Ray.—I have lately tried the marking ink for which you gave a recipe in the "E.M." of 20th August last, and found it too light in colour, and so thin that it ran when used on long-cloth. I therefore doubled the quantity of gelatine, bichromate of potash, and nigrosine, adding only very little water; but the same defects—want of blackness and too great liquidity—prevent me from using the ink. Perhaps Mr. Ray can kindly tell me how to correct these. I find that the nigrosine—i.e., aniline black obtained from an unexceptionable source—is not a good black, being too brown. Chloride of lime (so-called) removes the ink.—L.

[60275.]—**New Banjo.**—The great difficulty in making a brass Dobson banjo is this: you cannot heave down the vellum without having to remove the pan (and in your case the staff), which would be very inconvenient when about to perform. If you turn the bolts upside down, it means a very thick flush hoop, independent of the unpleasantness in having the ends of the bolts digging into your wrist while playing, and when made it would be very heavy. My advice is: If you must have a Dobson, make it of wood; if a metal one, make a modern silver one. It will cost less, have a better tone, look better, and be saleable.—Sam Koe.

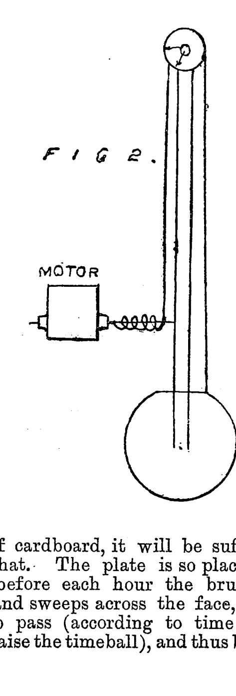
[60316.]—**Electric Time Ball.**—To "Original Querist" and "Watchmaker."—The accompanying sketch gives circuits, further developed.

FIG. 1.



On second thoughts I have dispensed with relay. The gong is connected electrically either through framework of clock or by a special wire to the minute hand, which carries a little brush at the point composed of a few short pieces of fine platinum wire, like the connections of incandescent lamps are made of. The contact piece to which one battery wire is attached is also a little platinum plate, mounted on a small block of wood or vulcanite to insulate it from clock face. If the

FIG. 2.



latter is of cardboard, it will be sufficiently insulated by that. The plate is so placed that a few minutes before each hour the brush at end of minute hand sweeps across the face, taking, say, a minute to pass (according to time required by motor to raise the timeball), and thus by completing the motor circuit, for a time raises the ball. The time ball having risen breaks the circuit by the mercury contact; the slot in the brass guide sliding on the pole; being long enough to allow the ball to continue rising for half an inch or so after the catch has fallen into the slot, so as not to require too precise an adjustment of the mercury contact. Then when the hour strikes the clapper or hammer of the clock (which must be insulated from the clock, as by a wooden stem, to the metal head of which another battery line is attached, as by means of a very small slack coil of the battery wire, so as not to interfere with the striking movement), closes the other circuit through the electro-magnet at the top of the pole, which works the catch as explained in my two previous replies, and the ball sinks. The gong is connected, as shown, to the battery, and the minute hand by wires soldered to it. The actual mechanism of raising the ball is shown in Fig. 2, being a cord passing through a small pulley in the head of the pole, and carried (if necessary, through one or two small pulleys) to the shaft of the motor armature, which should be made specially long for this purpose, so as to project, say, 4in. beyond the standard, on the side remote from the commutator. All pulleys beyond the one at the head of the pole should, however, be dispensed with if possible, as they put a greatly increased load on the motor. If you are resident in London, and intend putting up one of these timeballs, I should be pleased, if you care to advertise your address, to help you personally in the construction of the apparatus, as I am interested in the matter myself. I should use No. 16 for the wires, well covered for the out-of-doors portions.—E. Conry.

[60334.]—**Falling Bodies.**—The violin string, as cited by "Dubliniensis," illustrates well that a force directed to a centre, and varying directly as the simple distance therefrom, makes a body revolve always in an equal period, whatever the ellipticity or whatever the size of the orbit. In the case of a non-resisting interior of a homogeneous earth, this period would be the same as that of a satellite revolving just above the surface—namely, somewhat under 84 minutes. How I came to make it two hours I cannot tell. It must be to a month of 27·32 days, as the square root of cube of earth's radius to the square root of cube of moon's mean distance, or as $1 : \sqrt{60{\cdot}27^3}$. Whether the motion were round a circle, or to and fro in a straight line, and the path 25,000 miles, or 25in., the period would be the same. "Puck" was able to fly almost exactly twice as fast as a gravitating satellite.—E. L. G.

[60334.]—**Falling Bodies.**—Although "Vulcan" has dismissed my reply to a late question, while coolly declaring himself incapable of discussing it, and though the question that he now puts directly to me is accompanied by a sneer, I will answer it for the sake of some other readers. He asks my authority for saying that every (central) ellipse, described under the action of a given central force varying directly as the distance, will be described in the same time; and he considers that this statement is fit for a work on astrology. This very familiar principle is not a matter for authority any more than a proposition in Euclid is so; but if we must treat it as such, let us refer to one out of the host of authorities on this point —viz., Newton's "Principia," Book I. Prop. X. Cor. 2. There is, however, no astrology in that work. As one reader, at least, "M. York," prefers "Vulcan's" acknowledgedly uninformed opinion to my at least professed mathematical calculation, both of us writing anonymously, I beg leave to mention that the mathematical formula I have given for the axis minor, of which there has been so much to say, follows at once and most easily from the first of the pair of equations marked (5) in p. 160 of Williamson and Tarleton's "Dynamics"; and anyone can make out for himself whether my arithmetical calculation from said formula is correct or not. I repeat that if the earth were spherical and homogeneous, and if a stone could be dropped from the Equator and fall freely through the body of the earth, it would describe, in about 80 minutes, an ellipse whose centre would be at the centre of the earth, whose axis major would be the diameter of the earth, and whose axis minor would be about 520 miles; the stone would miss the centre of the earth by about 260 miles. The earth, however, increases in density in descending, so that the central part must be something about 10, water at the surface being 1. This would prevent the orbit of the stone being an ellipse, and would make the stone pass much nearer to the centre of the earth, probably as near as about 170 miles. It is impossible to calculate this, since the law of the increase of density is not known. Laplace's proposed law of this is believed by Thomson and Tait to be not very wide of the mark; but that is all that can be said of it. There is much of "Vulcan's" last communication that I do not understand; it seems to me to be ironical. I happen to know all about Airy's pendulum experiments in Harton Coal Pit, near South Shields, having read

the original account in *Phil. Trans.* 1856, p. 341; but as "Vulcan" only laughs at anything I say, I will pass it by now. He considers that the pressure at the centre of the earth must be "slight"; in this he differs from the mathematicians. Taking the mean density of the earth at Cornu's figure—viz., 5·56, which is unquestionably the nearest to the truth, and must be exceedingly close to it; it requires only the simplest integration to see that the pressure at the centre of the earth would be, for a homogeneous earth, just about 11,000 tons to the square inch; the actual pressure may be safely estimated, as it is by some, at about 17,000 tons per sq. in.—DUBLINIENSIS.

[60428.]—**Silvering Glass.**—Does it matter if I use finish in the place of alcohol stated in Mr. Brashear's letter, Vol. XXXI. p. 27? Also, is the process good when glass is laid and solutions poured on? Thanking you for the reference, will it be troubling you too much to ask you to state the Rochelle salts process.—G. H. H.

[60455.]—**Chemical.**—I am exceedingly obliged to "Nun. Dor." for noticing my query, and with the following explanations hope it will no longer remain a puzzle to him or any other kind friend who can assist. The mark is to be raised—i.e., in relief—so as to be felt, the pencil to be used dry. I do not require the marks to stand pressure.—W. R. L. R. N.

[60506.]—**L.T. and S.E. Side Tank Engines.**—I believe these engines weigh about 40 to 42 tons.—SCALES.

[60516.]—**Railway Locomotive Returns.**—I think this querist can obtain what he wants in the Continuous Brake Return for June, 1886. It is sold by the Queen's printers.—SELF HELP.

[60524.]—**Hide and Feather Press for China.**—Any of our hydraulic engineers can supply a suitable press.—NUN. DOR.

[60534.]—**Dynamo.**—The best thing "Anxious" can do is to call in an "electrical engineer," who, if he cannot put matters right, will be able at least to put the query in some more definite shape than it appears at present.—C. KERR.

[60538.]—**Formula for Train Speed and Brake.**—In Molesworth's Pocket-book "Goods Fireman" will find some formula which will enable him to calculate what he wants. If he will refer to your back volumes, I think he will find some tables about the action of brakes.—J. P. C.

[60540.]—**Tricycling Matters.**—I agree with "Gamma Sigma" that spade handles are preferable to the cross handle in steering in many ways. There is need for improvement in them, however. For instance, the small chain wheels attached by means of a sunk "feather" to the steering rod, have a tendency to work loose, giving a certain amount of play where there ought to be none at all. I am referring to the new Rudge Rotary tandems. If these small chain wheels could be rigidly fixed to the steering handles, the steering of these tricycles would be excellent, as they are fitted with stuffing boxes; but, with my machine, after a few hundred miles the feather which keys the chain-wheel has worked quite loose. As regards gear, I should much like to know the general opinion held by riders, and gained by experience as to the best-sized driving wheel to be geared to. My machine was furnished with a 48in. wheel geared to 52in. This was very well for ease and speed on the level and downhill, and my wife and I could, by much exertion, climb up most hills we came across. But after a long day with a stiff wind, a moderate hill became a teaser, and I altered the gearing wheels, and my machine is now geared level—viz., to 48in. My opinion, however, is that this is too high. Many journeys are full of steep hills, and to me there is no pleasure in dismounting and pushing, and I think this should only be necessary under exceptional circumstances. I may add that it is not the "personal equation" of the partner in my journeys that is in fault, for that would, in truth, tell the other way.—JOHN BELL.

[60542.]—**Photography.**—What advantage does the querist expect to gain by the use of citrate of silver? Or, to put it in another way, where did he find any mention of its use in photography?—E. G. M.

[60546.]—**Phantasmagoria.**—The oleographs must be transferred to glass for use in the lantern, unless the querist intends to use the reflecting lantern.—E. K.

[60547.]—**Letters on Glass.**—Why not silver first and paint afterwards? The question is rather an incomprehensible one.—J. T. M.

[60555.]—**Sardines.**—It would be altogether unprofitable to guess how the modern sardines are put up; but the true sardine (*Clupea sardina*) is a small fish found in the Mediterranean off the coast of Provence and along the shores of Italy. The fish are washed in sea-water, sprinkled with salt, and hung up in the sun to dry, as may be readily guessed from the fact that the eggs of flies can often be found in them. The fish are then boiled in oil, the high temperature thoroughly cooking them, and are then packed in tin boxes, which are filled with olive oil (should be), and immersed in a bath of brine which is hot enough to drive out the air from the tin, which is then soldered up hermetically. Thyme, bay, tarragon, and other herbs are used to flavour; but the majority of sardines which reach this country come from the Bay of Biscay, and are simply small fish.—SAML. RAY.

[60591.]—**Tempering Springs.**—I am sorry if my fun has given poor "F. G. F." pain. He is quite right as to my knowing nothing of getting the temper of springs with a stick. The plan of using the end of a hammer handle to see if the plate is hot enough to work is, of course, familiar to me; its object is simply to avoid working the steel at a temperature at which it would be injured in quality, and has nothing to do with tempering *per se.*—SPRINGEE.

[60622.]—**Astronomical.**—"D. D., Youghal," cannot have given very much attention to his planisphere, if fancying that with your eye placed "at the South Pole" of a transparent globe, any circle thereon will appear "an oval or ellipse." Your eye must be away from its surface, either within or outside the globe, to see either the horizon or any other circle projected as an oval. With your eye in the surface, every circle thereon that appears not as a straight line becomes a circular one; and the kind of planisphere thus formed (called stereographic) may doubtless solve many problems, and be as useful as he says. But none with elliptic lines will do so.—E. L. G.

[60623.]—**Dynamo.**—TO S. AND E., COVENTRY.—Thanks for your kind information on this head. Could you also inform me (1) if there is any scale by which one can ascertain, on procuring the gauge of wire on the armature of an absolutely strange dynamo, how much current that armature will bear without burning, so that a man having to use a dynamo about the capacity of which he has no statistics, can judge how far he may venture to decrease the external resistance by adding more lamps in parallel, without risking burning the armature, in case the machine should be capable of producing more current than the armature coils will actually bear, as I understand is the case with some good dynamos? I have been told by friends of machines having been burnt by switching on too many lamps at once, and I wish to obtain such information or scale as will enable me to avoid this contingency while working a strange machine up to the maximum capacity short of this. (2) Can you recommend me to any book in which I can find clear directions and tables for calculating the gauge and amount of wire necessary to produce required currents and electromotive forces with various speeds? I am working through Prof. Thompson's "Dynamo-Electric Machinery" in the hopes of finding the information I want; but it seems to my limited faculties terribly complicated and intricate; and as for the long articles with algebraical formulæ published at times in the electrical journals, I cannot make head or tail of them, though tolerably versed in algebra and arithmetic. It seems to me that every formula cited depends on two or three other formulæ or unknown quantities, the means of obtaining which are not shown. I am much interested in electrical science, and having the necessary leisure and means should like to feel myself able to construct a machine to a required power, or at all events make the necessary calculations for the purpose.—TORBAY.

[60638.]—**Mechanics—Compound Wheel and Axle.**—"Novice" is not quite correct in the ratio of the velocity of the handle to that of the weight raised. Circumference of largest axle = 18·8496in. (as he states); circumference of smallest axle = 12·5664in.; difference, 6·2832in. As the rope forms a loop it will be double, therefore height-weight raised in 1 revolution $= \frac{6 \cdot 2832\text{in.}}{2} = 3 \cdot 1416\text{in.}$; circumference or distance through which the handle will travel in 1 revolution = 124·5664in. Ratio of velocity $= \frac{124 \cdot 5664\text{in.}}{3 \cdot 1416} = 40$. Therefore, ratio of velocity of handle to weight raised is as 40 to 1. The power or advantage gained will be, as he states, as 40 to 1—that is to say, 1lb. applied at handle will raise 40lb. by the rope—neglecting friction. This could be obtained by using radii in each case, not circumferences. Ratio of handle to weight $= 20 \div \frac{3-2}{2} = 20 \times \frac{2}{1} = 40$, or 40 to 1.—DUD DUDLEY.

[60690.]—**Wood Carving.**—TO "W. A. S. T."—The meaning that I attach to the term "common ornaments" in this case is, ornaments which are employed to relieve the heaviness of a piece of work, but do not contain any considerable amount of artistic value. Are there not peculiar shaped chisels for marking out the form of the carving? If so, please give their names, as I have to pencil it at present, and when I begin to remove the superfluous wood I lose the marks.—G. H. H.

[60700.]—**To Draughtsmen, &c.**—Take a piece of tinned iron or slate. Draw a circle (as large as convenient) carefully with fine point compasses. Draw a diameter, and starting from diameter, step out circle into as many divisions as you have time and patience for, or use two circles, one inside the other, one for even, the other for uneven divisions, then join the first of each division with the centre, marking what part of a circle each line represents, and you have an apparatus for all time. To find, say, the eleventh of a given circle (smaller than your diagram), describe this circle from the centre of diagram and touching the diameter and line marked 11, and you have your eleventh between these points. Should like to know how you managed with trig. hitherto.—HENDON.

[60700.]—**To Draughtsmen, &c.**—The sector that seems unaccountably so gone out of use, that I have not seen one in any of the instrument shops for years, is merely a single-jointed, broad, folding rule, with the two limbs exactly alike, each having a scale of equal parts and some other scales, all on lines radiating from the centre of the joint. The other scales are usually one of chords to every degree up to 60° or 90°, and one of tangents up to 45°. But very large and good ones, of ivory, or even metal, I think, were made for navigators, with some other lines. The fault of any such tool, with no means of fixing the opening, must always be like that of unstrutted compasses, that the joint is either too easy to be trustworthy, or too stiff to admit of accurate adjusting. There should always be struts adjustable with a screw. The sketch I gave of angle-divider like lazy-tongs was by memory from a patent specification, about three years old. I see how it might be greatly improved, but need not say, as "Workman" only speaks of dividing circles, not angles. But though the former is a far more likely operation to need than the latter, I greatly doubt the remunerativeness of any patent invention for it, however perfect.—E. L. G.

[60700.]—**To Draughtsmen, &c.**—May I be allowed a word in extension of my reply on p. 182, which seems to be not exactly acceptable to "Workman"? It is an old workshop motto that the practical man will do his job while the scheme-a-jack is fiddling with his protractors, &c. Now, first, as to dividing straight lines: Most odd numbers come reasonably near to some number compounded of powers of three and two, and a line can be always roughly divided into these fractions by the eye alone. Thus, given a line to divide into, say, 13 parts, down goes one finger in the middle, and another at half again; this quarter can now be divided by eye into three, giving 12ths of the whole. Now set the dividers at about $\frac{1}{13}$th less than that length, and take 13 steps along the line. Say we do not reach the end by $\frac{1}{2}$in.; open the dividers (at a close guess) $\frac{1}{13}$th that quantity. We shall probably, on re-stepping, find we are "out" by a quantity so small as to require only the minutest touch either way to correct $\frac{1}{13}$th of the error, and give a practically perfect setting. To divide a circle into 19ths (say): if we can get at the radius—i.e., put one leg of dividers into centre, and one on circumference, we can now put both legs on circumference, and get $\frac{1}{6}$th of same. Divide this by eye into 3, and we get 18ths. Now set dividers about $\frac{1}{19}$th less than this; and after stepping round, alter same, not more than $\frac{1}{19}$th of the error: when we are within the slightest touch of the truth. When we have to take more than two steppings before the final correct one, it shows that we have failed to bear in mind that we have only to correct a fraction of the accumulated error dependent on the number of steps taken. And this final tentative process is not eliminated, even though we are able to

> "Declare by lines and tangents straight,
> If bread or butter wanted weight:
> Or wisely tell what hour o' th' day
> The clock did strike, by algebray!"

If the centre of the circle be not accessible, we may caliper the diameter, and halve it by laying off equal distances from both ends, and dividing by eye any small space left in the middle; or if the outside (of a column) is all we have to work upon, we may wrap a piece of paper round it, then divide that at the bench. Even when a small portion only of a circle is available we may lay it out on the board by taking two straight-edges, secured at a suitable angle, and marking where these touch the circle (tangentially). Lay down on the board, and trace perpendiculars from the marked points. These will be radii of the circle, and will cross at the centre, from which the circle can now be struck. There is a simple instrument for enlarging drawings, &c., dependent on the even stretching of an indiarubber cord. Possibly a graduated band might be available for rough dividing purposes by stretching as required. In conclusion, it has been the painful experience of many who, like the writer, once thought themselves very clever, to find that a practical man will do his

work while the theorist is thinking about it, and he remembers, with a sigh, how Mark Twain took a Latinist up the Riffelberg, and yet boiled his barometers for altitude — and for soup! (An allegory.)—NEPHESH.

[60726.]—**Engine Flywheel.**—Many thanks to "T. C., Bristol," for his kind reply. I was thinking of purchasing a 6 or 7-horse second-hand vertical boiler, as the one I have is too small, and working it to say 50lb. pressure, do you think that would do? The pipe that supplies the steam to the engine is $1\frac{3}{8}$in. in diameter. I shall be glad of any information on the subject.—STEAM-ENGINE.

[60728.]—**Steel and Iron Tubes.**—I am much obliged for the reply given to above query by "Engineering, Manchester"; but he does not say if the formula he gives is a safe working pressure for "riveted" tubes, or whether any allowance is to be made afterwards for rivets. Perhaps he will kindly enlighten me.—PERPLEXED.

[60741.]—**Mensuration.**—Turn empty vessel on its side and hold a board against open end so as to half-close it. Fill with sand or grain to the level of the board, and set the vessel upright again. Mark where the sand then stands as "half full," or weigh the water nearly to fill vessel, and pour in half the quantity. Mark as before.—GLATTON.

[60744.]—**Question in Dynamics.**—According to "M.I.C.E., Bath," the monkey raises *m*, and *m* raises the monkey. Will he explain how the monkey can ascend while the rope, which it must continue to grasp, is descending? Surely, when "M.I.C.E." uses the word "bounds," he does not imagine the monkey springing up through the air. Such springs could only be given, if at all, by using the rope to "take off" from—i.e., by increasing the downward pull on it, which, as I said last week, would set the system in motion in rising and the monkey falling. So far as first starting the motion goes, the case is precisely the same as that of a man standing on one scale of a balance and trying to pull himself up by his arms to the end of the beam above him: the more vigorously he tries to raise himself the faster will his end of the beam go down; the beam will right itself when the man simply lets his dead weight hang from it, but the motion of the rope once started must continue and be uniform, there being no force available to stop it. Any fresh effort, if it were possible, on the monkey's part would accelerate it. If, instead of pulling at the beam with our arms, we raised our body by pushing against the scale with our legs, the result would be the same; we should practically increase our weight for the moment and give the scale a downward motion. The experiment may be tried on the new weighing machine at any railway station. Bend your knees before you drop your penny through the slit, and when the index is stationary at your true weight, raise your body by straightening them.—W. A. S.

[60744.] — **Question in Dynamics.** — If "W. A. S." will read again my answer on this question, perhaps he may be induced to reconsider his opinion somewhat. I do not see myself that there is so very much difference between our answers, save as to whether the motion would be accelerating or regular. Mine was that "in practice the jerking of the string would probably add to his weight a slight momentum sufficient to start the other mass, when slow motion would result, accelerating gradually through momentum"—i.e., the weight would go up and the monkey down. His answer is, "on the least contraction of the monkey's muscles in the effort to rise, up goes *m* and down goes the monkey as far as the rope will allow." The problem is not of much importance, as weightless strings and disregard of friction do not come within the range of practical mechanics; but as regards the motion "accelerating through momentum," I reason thusly. We are told by the original query to "disregard friction." Presuming this to include friction of air as well as of pulley (as it seems to me from the tenor of the original question we are intended to do), there would be nothing to stop the weight from rising till the pulley was reached, if the weight had been set in motion by a single impulse, for the force of gravity on the weight would equal the ditto on the monkey (producing the normal equilibrium); and this having been disturbed by the first bound of the monkey, motion would ensue, and would continue (there being no counteracting force, as weight of string and friction are to be disregarded); that is to say, there would ensue motion of mass and monkey respectively upwards and downwards, and both at a regular speed. But our quadruped continues his aspiring course ("begins to run up the string"), and every successive bound of his upward progress adds a fresh impulse to that which has already set the weight in motion; consequently, the latter travels upwards faster and faster, or, in other words, accelerating motion is produced. Even if the resistance of the air were not disregarded, the continual impulse of the monkey's successive bounds would probably more than counterbalance the slight resistance of this, and if so, the surplus force of this continual impulse, however small, would suffice to produce accelerating motion. What does "M. I. C. E." say? He has worked out the matter much further than either of us. I do not quite see what "W. A. S." means by there being a trap in "Humbugged's" query. It seems to me straightforward enough; but if "W. A. S." is right, then "Humbugged" is a very wicked man to set traps at all. There are quite stumbling-blocks enough in this sad world without his adding to them.—E. CONRY.

[60753.]—**Light.**—TO W. G. PENNY.—I am sorry Mr. W. G. Penny has misunderstood my meaning, for I don't *really* think that to say a ray falls obliquely on a surface is to imply that the surface is flat. But what I intended to imply was, that the retina is curved so that the rays *shall be* more nearly perpendicular to it, when one does look to the side of a star; and, secondly, that the vision is formed by a cone of rays of which only *one* is perpendicular. And, lastly, that the looking to the side of a star does not alter the angle of the ray as regards the retina sufficiently to account for the improved vision, in my opinion. Hence my query.—M., York.

[60762.]—**Flywheel.**—If the piston speed is the same, the length of the stroke will not alter the power of any engine. The exact power of your engine depends on the piston speed per minute and the mean pressure in the cylinder; but $6\frac{1}{2}$in. cylinder will give about 4-horse nominal. You can drive direct from flywheel; but as the width of face is only 4in., you cannot use the fast-and-loose pulleys which are on saw spindle so as to stop saw without stopping the engine every time you require to sharpen or change a saw, which will be very often if you are cutting anything over a 6in. batten with such a small engine. The distance between flywheel and saw pulley should not be less than 10ft., or as much more as possible. But I should strongly recommend you to put a small countershaft between engine and saw, so that you can get about 1,100 revs. per minute, and also you can then get a wide pulley to drive your fast-and-loose pulleys on saw spindle, as it is not safe to run a saw-bench without it is possible for the sawyer to stop his saw without having to leave the bench, as a new saw would be completely spoilt if it got hot in the middle of a long cut before the man could get to the engine to stop it, as he could not leave the log without lifting it off the bench or running it back, both of which take time, and in the mean time the saw would have got so hot the temper would have been spoilt, which means throwing away the saw, as a burnt saw is not like one simply sprung, which hammering will put to rights. —MACHINIST.

[60765.] — **Area of Sewer.** — None of the answers to this query are correct, as no allowance is made for the increased velocity of flow in the larger sewers. "Student" does not state the rate of fall; but, for illustration, let us suppose it to be 1 in 500, and that the larger sewers are to be laid at the same fall. The velocity in the 2ft. 0in. sewer running full would be 189ft. per minute. In a 2ft. 6in. sewer it would be 213ft., and in a 3ft. 0in. one 234ft. Therefore, if "Student's" 2ft. sewer carries the sewage of 5,500 persons, a 2ft. 7in. sewer would do for 10,000, and a 3in. 0ft. one for 15,000. I can hardly understand though, if the fall is anything like what I suggest, how so large a sewer as 2in. 0ft. can be necessary for 5,500 persons.—W. W.

[60765.]—**Area of Sewer.**—Let it be *granted* that a sewer 2ft. in diameter *is* sufficient to remove the sewage from a population of 5,500 (and, as a matter of fact, is large enough to discharge 1,205 gallons per minute, or 1,735,200 gallons per day of 24 hours r unning half-full, sufficient for a population of 34,704, allowing 50 gallons per head, at the very low gradient of 1 in 1,056). It is asked, 'What size sewer would be required for a population of, say, 10,000 or 15,000. (In finding the size of a sewer, it is necessary that the amount to be discharged should be first obtained; then the gradient should be fixed so as to enable the sewer to be self-cleansing—that is, the velocity should not be less than 3ft. per second. It will be seen that even a sewer 2ft. in diameter is much too large for even a population of 34,704.) The following formula, which was adopted by the late Mr. Beardmore, will be found very useful in arriving at the velocity—

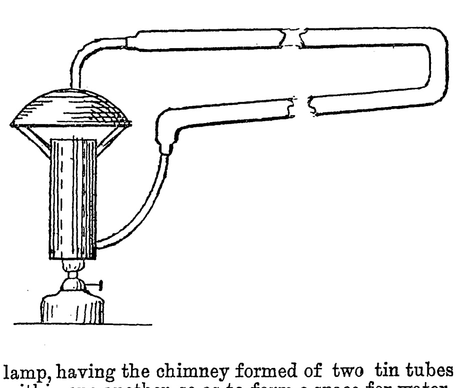
$$V = 55\sqrt{R \times 2H.}$$

R = hydraulic mean depth in feet.
= (in circular pipes) $\frac{1}{4}$ of diameter.
H = fall in feet per mile.
V = velocity in feet per minute.

—FRANK G. COLES, Southampton.

[60776.]—**Boiler.**—Your boiler is very small to drive a 6-horse engine with any amount of success, as you require about 6ft., or better still 8ft., of grate surface, and about 80 sq. ft. of flue surface, which you cannot get in such a boiler without you build side flues. If you do succeed in getting it in your boiler, the only one that will be satisfied will be your coal merchant, as the old dish-end boiler is at the best very wasteful, and when too small for its work, will burn any amount of coal.—MACHINIST.

[60774.] — **Heating Conservatory.** — I send the sketch requested. It consists of a paraffin



lamp, having the chimney formed of two tin tubes within one another, so as to form a space for water. This space is connected to a dome-shaped top, having a flat bottom, the connection being two small tubes. The flow is from top of this, and return to bottom of stem of T.—T. C., Bristol.

[60784.]—**Locomotives.**—I send the following details, which I think will be found accurate:—The Liverpool had cylinders 18in. diameter by 24in. stroke; 292 tubes $2\frac{3}{16}$in. external diameter and 8 tubes $1\frac{3}{4}$in. diameter, all 12ft. 6in. long. Heating surface of tubes 2,136 square feet; of firebox 154 square feet; total, 2,290 square feet. Grate area $21\frac{1}{2}$ square feet; 1 pair driving-wheels 8ft. diameter; 3 pairs carrying-wheels 4ft. diameter; wheel base 18ft. 6in.; length of frames 27ft. Weight of engine, in working order, on four leading wheels 17 tons, intermediate wheels 6 tons, driving-wheels (behind firebox) 12 tons; total, 35 tons. Weight of tender 21 tons. This engine conveyed express trains between London and Wolverton for some time, and in one case took forty carriages within time; but its weight and length proved too great for the permanent way, and it was withdrawn. The principal features in the design of the "Folkstone" were described as consisting in the boiler resting upon three points; one on the centre of a cross-spring, which bears upon the axle-boxes of the driving-wheels, and one on each side in front, on compensating springs, each of which bears upon the two axle-boxes of the supporting wheels. The other principal features consist in communicating the power from the inside cylinders to a crank-axle attached to the frame, and thence by means of coupling rods to the driving-wheels behind the firebox, the rods being arranged to act as "counterweights." The boiler was 4ft. 1in. diameter, 10ft. 8in. long, 184 tubes 2in. outside diameter, 11ft. long, cylinders 15in. diameter, 22in. stroke; driving-wheels 6ft., and carrying wheels 3ft. 6in. diameter, wheel base 16ft.; length over all 24ft. The whistles of the new Caledonian engines are organ whistles. I regret that I can give no information about the North British Railway.—A. W. B.

[60784.]—**Locomotives.**—I am sorry to say I cannot answer the first part of your query, as I have never been down there. The following description of the Liverpool is to be found in D. K. Clark's "Locomotive Engine":—Cylinders, 18in. by 24in.; 292 tubes, $2\frac{3}{16}$in. external diameter, and 8 of $1\frac{3}{4}$in., 12ft. 6in. long; surface of firebox 154·434ft., of grate $21\frac{1}{2}$ft., of tubes 2136·117ft.; total heating surface 2·290ft.; two driving wheels, 8ft. diam.; six carrying wheels, 4ft. diam.; length between centres of extreme wheels, 18ft. 6in.; total length of engine, 27ft.; weight of engine, charged, 35 tons, or 12 tons on driving wheels, 17 tons on four leading wheels, and 6 tons on the two intermediate wheels; weight of tender, 21 tons; total weight, 56 tons. This engine conveyed the express trains between London and Wolverton for some time, and in one case took 40 carriages within time, thus exceeding the combined duty of three ordinary engines. Its excessive weight and length, however, quickly threatened the stability of the permanent way, and induced its retirement from active duty, without impugning its title to be regarded as the "most powerful locomotive in the world." The Folkstone was one of eight engines built on the same plan by Messrs. R. Stephenson and Co. for the S.E.R. The principal features in the arrangement of these engines were described as consisting "in the boiler resting upon three points, one on the centre of a cross spring, which bears upon the axle boxes of the driving wheels at the back of the firebox, and one on each side in the front, on compensating springs, each of which springs bears upon the two axle-boxes of the small supporting wheels. The distribution of weight is for the purpose of preventing oscillation, and at the same time to insure, under all circumstances,

a uniform weight upon each wheel, producing a greater amount of adhesion upon the driving wheels with a given weight than with ordinary engines. The other principal feature consists in communicating the power from the inside cylinders to a cranked axle attached to the frame, the same as in ordinary engines, and thence by means of coupling rods to the driving wheels behind the firebox, the rods being arranged to act as counter weights to the inside connecting-rods, &c., the proper balancing of which is of much importance. In the Folkstone the boiler is 4ft. 1in. diameter, and 10ft. 8in. long; two driving wheels, 6ft. in diam.; and four bearing wheels, 3ft. 6in. diam. The cylinders were 15in. by 22in.; 184 tubes, 2in. external diam., and 11ft. long; extreme length of engine frame, 24ft.; between extreme wheel centres, 16ft.—A. T., Queen's College, Cambridge.

[60799.]—**Screw-Cutting.**—The figures given by "T. C., Bristol," and "Dynamite," are incorrect. The height of a Whitworth thread is ·64 the pitch, therefore, the hole in nut must be smaller than the tap by 1·28 the pitch, not 1⅝ p. A reliable rule for finding screwing size of a nut is to take 1·28in. as a constant, and divide by the pitch to be screwed, subtracting product from diam. of tap. This would make screwing size of 1¼in. Whitworth 1·068in. or 1$\frac{1}{16}$in. full. I gave this rule on Aug. 20-27, pp. 561, 583, and it is easily proved correct. Perhaps the readiest means of finding sizes required by the querist is to take them from a steel rule marked for the purpose, one of which I have. —H. O., Glasgow.

[60801.]—**Mechanical.**—I thank Mr. S. Bottone for answering above query. Will he still further favour me by stating how I may know the resistance of plating bath, &c.?—T. L. H.

[60804.]—**Burgin Armatures.**—The heating is due to heating of the cores, or to an injuriously large current. This excess of current may be due to a partial short-circuit in the machine or leads. Perhaps the machine is running too fast. If the brushes are in wrong positions the E.M.F. and current will be diminished. The heating cannot be due to this cause. In a series machine, if the current through the armature is greater than that through the lamps, it is certain that there is a short circuit somewhere.—G. Bowron.

[60804.]—**Burgin Armatures.**—We have seen a machine called the Franklin (which is a Burgin not made by Crompton and Co.) go on as you describe. The fault, primarily, was excess of current due to bad regulation of the arc lamps; but when the insulation once becomes defective the coils may give way at any minute. You are probably overworking the machine. Take one lamp off and drive slower.—C. D. Barker and Co.

[60805.] — **Accumulators.**— The E.M.F. of each cell rises to 2½ volts when gas is given off. The E.M.F. of 26 cells is therefore 65 volts. The E.M.F. of the dynamo will not be much above this. As the current is proportionate to the difference of these electro-motive forces, it will be much smaller. The power required to drive a dynamo is proportionate to the strength of the magnetic field due to the field-magnets, multiplied by the current in the armature. When the cells are fully charged there is a slight rise in the strength of the field-magnets; but the current in the armature is much smaller than before. The load is, therefore, less.—G. Bowron.

[60806.]—**Storage Battery.**—If I remember rightly, last winter a number of E.P.S. accumulators were fully charged in London, then emptied of the acid and sent to Edinburgh. They were there refilled, and the charge was used to light a large hall one night for a meeting at which Mr. Gladstone delivered a speech. You would want eighteen or twenty accumulators for the arc, and they should have a capacity of at least 30 ampère-hours. A considerable time might elapse between charging and using the current, if the cells were well insulated and the acid left in. Without the acid I cannot say how long, never having tried it. —W. A. W.

[60806.]—**Storage Battery.**—The E.P.S. Co.'s (of Millwall) portable cells will do all you require, and as they are completely closed in at the top like wooden boxes, you could take them from London to Edinburgh, or further, fully charged, taking the precaution of bringing a couple of cells more than the number you actually require to use, in case of one or two short-circuiting themselves and running out (electrically) on the journey. They are rather apt to do this when carried about, especially if jolted, as by trains shunting, and they are very dear in price; but for portability and power within a small space they are the best as yet in the market, and the E.P.S. Co. claim for them a higher percentage of efficiency (i.e., of charge returned in proportion to charge put in) than any other. The sawdust or paper-pulp cells are safe, and do not readily short-circuit, but their percentage of efficiency is very low, owing to their high internal resistance, caused by there being between the plates only about one-tenth or less of the battery acid that there is in even a non-portable cell with felt insulation, to say nothing of cells with "grid" and indiarubber button insulators. If, however, you wish to construct a set of these dry or semi-dry cells for the arc-lamp you mention, I can send you details of construction if you will give address, but it would take up too much space for the columns of "Ours." If you make the cells well and keep them dry and well insulated, you can leave them charged for weeks without any material loss. Accumulators have been thus left for nine months without perceptible loss; but all depends on make and circumstances.—E. Conry.

[60809.]—**Electricity Accumulator.**—Electricity can undoubtedly be stored so as to be commercially practicable, and is so stored every day; but your proposal, taking the minimum even, would be commercially quite impracticable, owing to the enormous cost. To give you an idea, a set were recently made for lighting a station; size of each about 1 yard square by 2ft. deep, containing some 30 plates apiece. It was anticipated that they would give 1,000 ampère hours each. As a matter of fact, they did not; but even had they done so, you would require about 400 such cells, at a cost of about £30 apiece. 10H.P. for 100 hours = 746,000 watts, and even if you had 50 cells in series—i.e., 100 volts (and that is a large number to have in series, owing to practical difficulties that occur with the connections)—you would then require 7,460 ampère hours, which would necessitate eight rows of such cells as those above—i.e., 400 cells—costing £12,000! For very large and long-continued currents like the one you mention, accumulators are quite impracticable, and if you wanted to get 10H.P. available for mechanical purposes, you would have to add on to the above figures 20 per cent. for loss through your motor. The size of accumulator I have quoted may seem large; but in actual practice it is certainly no larger than would be required for a yield of 1,000 ampère hours. There are no doubt cells in the market that profess a greater capacity for the same size; but they simply won't do it.—E. Conry.

[60813.]—**Narrow-Gauge Railways.**—If the chairs and fastenings are in proportion to the rails and sleepers, a speed of 40 miles per hour might be attained with safety.—Libra.

[60815.]—**The Sun's Radiation.**—The thermometer you speak of is a vacuum solar radiation thermometer, and consists essentially of two parts. First, a blackened bulb thermometer; and, secondly, an hermetically sealed and exhausted glass tube, in which the above thermometer is fixed before exhaustion. The difference between an air thermometer and the one in vacuo is the maximum solar radiation you have exemplified from the tables issued at the Meteorological Office. You suppose that if "the sun shines for any lengthened time, the modicum of air confined in the glass containing the vacuum thermometer becomes more heated, and so gives a higher record, &c." Now, this is entirely wrong, and in fact ridiculous, because how can you have "confined air" and an absolute vacuum in the same glass tube? Perhaps you are not acquainted with the fact that terrestrial radiation has an immense amount of influence upon an ordinary blackened bulb thermometer; but when isolated in an exhausted tube from this terrene radiation, the difference between its registration and an air thermometer in the shade at the same moment of time gives the absolute maximum of solar radiance, existing at that specific time. The bulb is blackened because in this condition it is capable of absorbing all the sun's rays. You can prove this by sprinkling some lampblack upon snow when the sun is shining, and watching it sink in whilst the white snow remains *in situ*. The use of the solar radiation thermometer may be employed where large crops and fruit trees are dealt with, to study the amplitude of radiant heat expended in fructifying and bringing organic life to luxuriance and maturity.—A. Treyer Evans, Newport, Monmouthshire.

[60816.]—**Gas-Engine.**—"Engine Driver" does not say who is the maker of his engine. If a Tangye, the explosion is due to too much gas, which causes the mixture to continue burning till the fresh charge is drawn in, which is fired by the still burning gases. If an Otto, it may be caused in two ways: 1st. The charge fails to light, and is exhausted down the exhaust pipe; the next charge explodes, and is exhausted on the top of the unexploded charge, which fills the exhaust pipe; the consequence is, that the charge in the pipe is fired too. 2nd. The cylinder becomes coated with a deposit of carbon, which gets red hot, and fires the gases before the proper time, some firing down the exhaust. As far as I know, there is no danger whatever. "Engine Driver's" explosions are probably due to the latter cause, as the cylinder had to be cleaned out. Could he not get some one to show him how to clean the cylinder?—then he could do it himself. About once in three months is the proper time, or oftener if necessary. I think "Invicta," in Vol. XL., mentioned some way he cured these explosions: would he let us have it, as it would be a boon, for I must say the explosions are rather startling, especially to the uninitiated?—A. Ricardo.

[60820.]—**Chamber Organ.**—I would advise "Taube" to have the following list of stops, as they would form a very complete little organ:—

Great Organ.

Compass C C to A in alt. = 58 notes.

1. Open diapason .... 8ft.
2. Stopped diapason .... 8ft. tone.
3. Flute harmonic .... 4ft.
4. Vox angelica .... 8ft.
5. Clarionet .... 8ft.

Swell Organ.

6. Lieblich gedact .... 8ft. tone.
7. Salcional .... 8ft.
8. Voix celeste .... 8ft.
9. Flute .... 4ft.
10. Oboe .... 8ft.

Pedal Organ.

11. Bourdon .... 16ft.
12. Violoncello .... 8ft.

Couplers.

Swell to great.
Great to pedal.
Swell to pedal.
Octave on great—upwards.
Octave swell to great—downwards.

3 composition pedals to each organ.
Great ventil. Choir ventil.

The materials I should advise you to make the pipes of are as follows:—Nos. 1, 3, 4, of plain metal; Nos. 5 and 10, of spotted metal; Nos. 7 and 8, of tin; No. 2, of oak, with clarabel treble; No. 6, of white wood, selected, and spotted metal treble, from middle C; No. 9, with circular mouths, the blocks, lips, and caps of pear tree, or triangular pipes with inverted mouths; No. 11, of yellow pine; No. 12, if of metal, zinc in low octave, and plain metal upwards, or if of wood, red wood bodies, box wood lips and caps. The vox angelica and clarionet are inclosed in a separate swell box, and form a small choir organ. The vox angelica is carried down from tenor C, with a small stopped wood bass, so is the salcional in the swell organ. Do not borrow basses if possible. The oboe should go through; the clarionet may stop at tenor C. As to cost, you may calculate the whole complete, bought of a builder, at £20 per stop, roughly speaking. As to space it would take up, that depends upon the situation the organ is to be put in. The metal pipes would cost about £30, and the keys £6. This is for the best material and workmanship, not the rubbish amateurs generally get. As to scales, the great op. diapason may be 2½ at tenor C; vox angelica, 1¾in.; salcional, 2in.; vox celeste, 1¾in.; violoncello, 2¼ at 4ft. C.; st. diap., 3½ at C C; gedact, 3in.; bourdon, 7in. at C C C. You will see I do not agree with Mr. Audsley in two matters—viz., the stop nomenclature and having a voix celeste. I consider for a chamber organ a voix celeste very desirable and very useful. The swells should have vertical shutters. If you advertise your address, I will tell you where you may get your pipes as they should be.—Uranium.

[60821.]—**Battery Work.**—To S. Bottone.—Aqua regia or nitro-hydrochloric acid for gilt, and pure nitric acid for silvered articles. Dynamo is much the best for the work. See my advertisements in "Sale Column." Refer to Sprague's work for recipes for plating solutions.—S. Bottone.

[60821.]—**Battery Work.**—To strip gold from a gold-gilt article, and to recover the gold, put the article in strong nitric acid mixed with a little common salt till the gold is removed. The moment the gold is stripped remove the article, then evaporate the solution to dryness, and melt the residuum with potash or soda. The quality is improved by melting three or four times, adding a little nitric each time. Roll out to the required thickness for anode. To strip and recover the silver from plated articles, get an enamelled pot and put strong sulphuric acid and a little nitrate of potash (saltpetre) into it. Place the pot on the fire and boil, then immerse the articles in the solution till the silver is stripped. Add nitrate of potash till the silver is quite off. Then dilute the solution very much with cold water, and place a sheet of zinc in it. This will throw down the silver in a metallic state. When it is all thrown down, pour off the liquid and wash the silver three or four times, then melt and roll out for anode. It will be seen that great care is required in stripping gold or silver, because if the article is kept in the solutions a moment after the gold or silver is stripped, the solutions become deteriorated with the base metal below; but of course this can easily be rectified by refining in the ordinary way if a chemically pure anode of gold or silver is wanted. The question as to whether a dynamo or a battery is best for plating cannot be definitely answered. It really

depends on circumstances. Operations on a large scale are mostly performed with the dynamo; but the battery does equally well if powerful enough for the work on hand.—BOBADIL.

[60823.]—**Electric Star Lamp.**—To MR. BOTTONE.—A small hand dynamo shunt-wound would be best for your purpose. Four 4c.p. lamps in series would have about the same resistance as one 16c.p. lamp; and if thus arranged, could be worked off the same lead. The others had better be used separately.—S. BOTTONE.

[60824.]—**Dynamo.**—To MR. BOTTONE.—To heighten the E.M.F., wind the entire machine with finer wire. To lower the ampères, insert the resistance in the circuit.—S. BOTTONE.

[60826.]—**Small Dynamo.**—To MR. BOTTONE.—Put about 1lb. No. 20 on the armature, 1lb. No. 16 on fields for the series, and 8lb. No. 22 for the shunt circuit. Drive at about 1,800 revs. per minute.—S. BOTTONE.

[60827.]—**Photography.**—No doubt any of the zincographic processes could be utilised for the republication of a book, but the cost would be much more than that of ordinary type reprinting.—B.SC., Plymouth.

[60827.]—**Photography.**—It would be very difficult, and perhaps almost impossible, to reproduce the diagrams you speak of by means of a photo-mechanical printing process, because a clear negative has first to be produced, which would be very difficult from an old diagram. You do not expect to reproduce the text as well? The negatives of the illustrations might be of some guidance to a wood-engraver, who could transfer them to wood blocks, which would serve him as a faithful representation.—A. TREYER EVANS, Newport, Monmouthshire.

[60828.]—**Knife Board.**—Both kamptulicon and linoleum are stuck to the boards by means of ordinary glue, and weighted down.—T. C., Bristol.

[60829.] — **Electric Star Lamps.** — "Stage Fairy" may use for her lamps a small portable battery of eight cells—price £2—which will run 5-candle-power and 2½-candle-power lamps very well. A flexible wire is not easily detected running from the battery to the fairy's batôn, and the lamp in her hair may be lighted by her standing on two small copper discs in connection with the battery.—BATTERY.

[60829.]—**Electric Star Lamps.**—A hand-dynamo should suit your purpose; a 20c.p. dynamo would weigh from 10lb. to 15lb. complete. The 16c.p. lamp should be of low resistance. I should recommend a Bernstein 20c.p. lamp requiring 7 volts 10 ampères, and four 4c.p. lamps of 8 volts 1½ ampère, each to be worked in parallel; the fairy lamps, if requiring 8 volts, can be worked with the 4c.p. lamps. If the voltage is less, a suitable resistance should be attached to the holders of the fairy lamps. The lamps can be arranged to work in series with a suitable dynamo, but an accident to one lamp would put them all out. The voltages and currents are given as examples, though I think they are the most suitable unless the leads are of great length.—G. BOWRON.

[60830.]—**Jaw Chucks.**—I think "A. L. K." will find all the information he requires in the articles on "Amateur Workshop" in the same number in which his query appears.—T. C., Bristol.

[60831.] — **Photography.** — The Dallmeyer R.R. and the Ross R.S. lenses are practically the same in angle, focus, and price; the Dallmeyer wide angle rectilinear takes in a larger field than the Ross portable symmetrical. Of the lenses mentioned I would recommend "Hazir Im" to buy the Ross R.S. and the Dallmeyer W.A.R. I do not think that anyone has as yet succeeded in making the gelatine emulsion, travelling about with it and coating the plates as required—the difficulties are too great; but for this style of thing why not use the old wet collodion process?—it is far superior in these circumstances. I will refer you to a book which you can purchase in Turkey, Egypt, or Russia, in the French language—Dr. Monckhoven's "Manual of Photography." You can also purchase his dry plates in most European countries. I bought and used them in Africa, and found them very good.—B.SC., Plymouth.

[60832.]—**Diatoms.**—In separating them from the mud on the slide, do not use the microscope, but a magnifying glass, a watchmaker's eyeglass, or the microscope condenser will do. The usual way to separate diatoms from the surrounding mud is to shake up well in water and pour off. The diatoms and the mud are of different sp. g., and can be thus separated.—B.SC., Plymouth.

[60832.]—**Diatoms.** — Diatoms are selected, transferred, and arranged by means of a single bristle, which must be fine, and taper suddenly at the end to a very fine point. There is no need whatever for two hairs or a split bristle, which, to my mind, would simply be barbarous tools to work with; moreover, I do not believe anyone ever did work successfully with such tools, although recommended in the early days of "selected" diatoms in textbooks on mounting, but probably at that time only the largest and coarsest diatoms were ever taken in hand. If "No Sig." will advertise his address, I shall be happy to forward him a suitable bristle, and to reply to other questions he may put on this subject.—DIATOM MOUNTER.

[60833.]—**Micro. Objectives.**—You can tell the angular aperture and also the magnifying power by using a ruled micrometer slide (sold by Watson, Holborn).—B.SC., Plymouth.

[60833.]—**Micro. Objective.**—To test the aperture of an objective, take a semicircular piece of wood perfectly flat, say, 24in. by 12in., and mark it in degrees as if making a protractor. Make a sort of carriage to carry the tube of a microscope detached from its stand, and put a wire through one end and into the board at the centre of the flat side, so that the carriage will move round the semicircle. Place a candle a few feet away on a level with the tube in a line with the degree marked 90, and swivel the carriage to first one side and then the other until the flame only shows a small crescent, and add together the angles through which it has been moved. "No Name" should get Mr. James Swift's little book, which will show him this and other tests of the quality of objectives. It was recently advertised in the MECHANIC, price 1s.—R. GILL.

[60834.]—**Noise in Boiler.**—I should think that the rising-pipe projects inside top of boiler, and so allows room for formation of steam. The pipe should be flush inside.—T. C., Bristol.

[60834.]—**Noise in Boiler.**—Perhaps you have fixed the flow pipe on the return pipe of the boiler, or the flow pipe projects through the top of the boiler and causes the steam to accumulate, which would account for the noise. Give more particulars. Did you fix it yourself, or a plumber?—W. W. E.

[60834.]—**Noise in Boiler.**—No doubt it is one of two things—either the flow-pipe (that is, the ascending pipe) is screwed too far through the top of the boiler instead of being quite flush, or the horizontal pipes fall from instead of to the boiler. If this is looked to, I have no doubt it will go right. —F. G. F.

[60834.]—**Noise in Boiler.**—This is due to the temperature of the boiling water rising a few degrees above the boiling point, and every time steam is formed it escapes with a sudden jerk like a slight explosion, and the temperature falling to 212° F., again rising and falling at each bump. Strew the bottom of the boiler with clean iron borings, which will break up that sudden rush of steam and make it keep at a constant temperature of 212° F. Failing this, repeat Faraday's experiment, only on a larger scale; fill the boiler with water, pour over the surface of it a layer of turpentine, so as to cut the atmosphere off; make up your fire, leave your house, and return in an hour's time after the water has "once boiled."—A. TREYER EVANS, Newport, Monmouthshire.

[60836.] — **Electric Light.** — Four portable household cells—price £4 4s.—would light "A. B.'s" room, 12ft. square, for some 20 hours with three low-resistance 8-volt 5-candle-power lamps. Six cells would run lamps of high resistance for a much longer period.—BATTERY.

[60836.]—**Electric Light.**—This applies to query 60848. A room 12ft. square would be well lit by two gas jets of 6 to 8c.p.; three 5c.p. lamps would be ample. I should myself prefer one 10c.p. incandescent lamp with flexible connections, which would allow the lamp to be fixed where I was working, or I should use two lamps with switches, only one being burned at one time. A 20-candle power dynamo would require from 2¾lb. to 4lb. of wire, according to the design; a ¼ H.P. engine will be large enough.—G. BOWRON.

[60836 & 60848.]—**Electric Light.**—To MR. BOTTONE.—To light a room 12ft. by 12ft., four 10c.p. or eight 5c.p. lamps would be ample. A dynamo, such as described in my book, but with a laminated armature 5in. by 2in., and fields 5in. wide, 7in. high, and ⅜in. thick, the armature wound with about ⅜lb. No. 20, the fields with 10lb. No. 16 (if in series) or about 6lb. of No. 22 if shunt wound, would do the work effectually. It would take about a ¼H.P. to drive it, at 2,500 revolutions.—S. BOTTONE.

[60837.]—**Steam.**—As regards model boilers, more depends on the method of heating than on actual cubical contents of boiler; but if it is, say, five times the length and five times the diameter of cylinder, it may be large enough. The rule you allude to is applicable to compound engines, in which case the low-pressure cylinder must be taken. But you hardly need telling that nominal horse-power is a mere trade term.—T. C., Bristol.

[60837.]—**Boilers for Model Steam-Engines.** —I have not had much to do with these; but the following extracts from back volumes may serve your purpose:—

Let D = diameter of cylinder in inches
L = stroke in inches
x = proportion of stroke passed by the piston before steam is cut off
n = number of cylinders to be fed by boiler
C = a constant = 15

Then, heating surface in square inches—

$$= D^2 \times L \times x \times n \times C$$

The thickness of a copper boiler should not be less than 20 B.W.G. or ·035in. If working pressure is 20lb., thickness of copper = $\cdot035 + [\cdot01\,(B - 3\tfrac{1}{2})]$ where B = diameter of boiler in inches. Or, simply $\frac{B}{100}$, remembering not to make it less than ·035. For any other pressure, subject to the same limit make thickness

$$= \frac{\text{Pressure} \times \text{diameter in inches}}{2000}$$

Of course, the converse is: Working pressure of a well-brazed copper boiler

$$= \frac{2000 \times \text{thickness}}{\text{diameter}} \text{ both in inches}$$

Always test to fully double the working pressure by pumping in cold water. The mode of staying the ends, &c., will depend upon the general design of boiler. The above rules only apply to the best brazed work. "Nominal" H.P. is now practically meaningless.—GLATTON.

[60838.]—**Mechanics.**—The whole apparatus is equivalent to a handle 20in. long, and an axle of 2in. diameter—that is, as 20 to 1; but as a loose pulley is used, this doubles the power, and gives 40 to 1, as you suppose.—T. C., Bristol.

[60838.]—**Mechanics.**—Each revolution of axle shortens loop of string by 6in., and therefore each side of loop by 3in. only. Weight would therefore rise only 3in., while power travelled though 125. Ratio of P to W = 1 : 40. Loop of string, of course, passes through pulley attached to weight. —E. F. S.

[60839.]—**Mounting Plates of Wimshurst Machine.**—To "SODIUM." — I have a pair of discs of 3ft. diameter, and only ⅛in. thick, and, after much consideration, adopted the following plan, which is eminently successful. The boss is composed of two pieces of mahogany, grain reversed, glued and screwed, 5in. × 1¼in. I first attach a disc of fine canvas or Drogheda linen, same size as boss, to the glass by means of the cement I have several times described in these pages, and next day I apply the same to the boss and the coarse linen. Support the glass carefully under the centre upon a flat table, upon a piece of drugget; place boss central by means of a lath and pencil mark, and place a heavy weight on same. If in warm room it will be firm next morning. I use a spindle of ⅝in. iron gaspipe, running in brass bearings, and find that, as the glass seems always to have been cooled unequally, and is under a strain or strains, it is much better, if possible, to avoid making any hole in same. I omitted to state that on spindle is a cast-iron faceplate, 4¼ diam., plate ¼ when turned up, and, with neck, measures 1¼ on the spindle, on which it is tightly shrunk, and end of spindle slightly riveted. In this are four wood screws so as to adjust the plates, which are never quite flat, which I do by means of a soft leather washer.—A., Liverpool.

[60839.]—**Mounting Plates of the Wimshurst Machine.**—"Sodium" will find the chief objection to mounting plates by simply cementing the glass without a hole flatly upon the end of the boss, is, that when so mounted they must be suspended at the extremity of the spindle, hence the driving band, and many other causes, set up vibration. A lesser difficulty will be found in getting the two plates to run parallel to each other; besides these mechanical difficulties, there always is the danger of the cement yielding while the plates are rotating, and thus allowing the plate to fly loose. Cementing a disc of hard fibre to the glass and afterwards securing this disc to the wooden boss with screws, certainly seems the best and the safest method. Breaking the glass, by screwing up roughly, only indicates the absence of a proper sense of touch in the final adjustment of the screws: practice will correct this. I certainly use the method frequently, and, — whether by good fortune or by good management I don't know, but the fact stands, that I never get breakage or failure. Another method which I submit to "Sodium," is to cut the hole in the glass rather larger than the diameter of the boss, then turn up a large diameter of bobbin of two thicknesses of hard fibre, cement the glass into the recess formed in the bobbin: he then will have the glasses with fibre centres, and he can attach them to the bosses without fear of breakage.—J. W.

[60841.]—**Porous Pots.**—Porous pots of high resistance are used for telegraphic work where long runs are required without attention. Their only advantage is that diffusion takes place less

rapidly than with the softer pots. If materials of uniform quality are used, the size of a cell has no effect on its E.M.F. If the cells in the table are round, the figures may be correct. If they are flat, the resistance of the larger sizes would be less in proportion.—G. Bowron.

[60842.]—**Flat Music.**—Hire a barrel organ for a month. When the piano begins, begin with your organ, always taking care to keep your time slower or faster than the piano. Persevere in this plan until the pianos come to terms. This will be less expensive and more effective than mechanical means.—Hendon.

[60844.]—**Steam.** — If you want to heat the whole mill at one time simply carry a 2in. pipe to top of mill, and then continue round the mill with 3in. pipes, having a fall to take condensed water down another 2in. pipe direct to boiler. Have a back-pressure valve in this where it enters boiler, and a small pet cock at highest part of pipe. Steam-pressure would be practically the same at top of pipes as in boiler, and the additional weight of condensed water is sufficient to open return-valve. Of course, boiler must be lowest point. It must be a very small engine to work with 356ft. of 2in. pipe; the condensation must be enormous. If all shut-off and pipes lagged, the pressure at end and in boiler should be the same.—T. C., Bristol.

[60846.]—**Electro-Deposition.**—The usual way of connecting vats to machine is to have thick copper rods from machine running the whole length of vats, connecting the rod for anode direct by a binding screw and copper band. The rod for cathode is connected to a resistance board, and from thence to vat; by this means you may regulate the current according to work under operation.—T. L. H.

[60847.]—**Faulty Coil.**—The absence of any increase of spark on connecting the condenser suggests that the fault lies in the connection of this apparatus—not an uncommon defect in early coil making. A spark of ¼in. from about ¼lb. of 36 s.c secondary is not, I should say, a bad result.—B. Harcourt.

[60853.]—**Artificial Teeth.**—The principal or main basis of the body of artificial teeth is felspar and rock crystal; but each manufacturer has his own special composition, shapes, and colours. E. W. Gough wants to know how he can fix them on gold plates. E. W. Gough had best put himself under training by serving an apprenticeship in the regular way, and in due course he will learn that, and other things dental besides.—Dens.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

Electrolytic Separation of Metals.—From solutions containing salts of various metals the metals may be completely and successively separated in a state of purity by using currents of different strengths. The current first applied must be only sufficient to throw down the most readily precipitable metal, but not the next following. The more of this first metal is deposited the feebler becomes the current, and finally a galvanometer introduced into the circuit is no longer affected; a sign that now none of the metal precipitable by the existing electromotive power is present, but only such saline solutions as do not conduct the feeble current, and consequently are not decomposed. If the negative electrode is charged and the electromotive power increased a second metal can be precipitated.—*M. Kilian.*

Propionic Acid.—Propionic acid occurs in considerable proportions in the tars resulting from the destructive distillation of resin at the temperature of bright redness. Propionic acid boils at 141·5° to 142°. Its sp. gr. at 0° = 1·0089; at + 18° = 0·9904. It remains liquid if cooled to − 50°. It dissolves in all proportions in water, alcohol, ether, benzol, and petroleum essences.—*Ad. Renard.*

QUERIES.

[60854.]—**F.C.S., F.I.C.**—Would any reader kindly say whether the Fellowship of Society of Chemistry and Institute of Chemistry can be obtained by one who is not acquainted with a Fellow? If so, by what means?—E. F. S.

[60855.]—**Pulleys.**—I should feel obliged if some of our readers could give me sizes of pulleys required for driving planing machine by flywheel 4ft. diam., weighing 3cwt. Also sizes of corner pinions for driving flywheel on anti-friction bearings.—Amateur.

[60856.]—**Battery.**—To Mr. Bottone.—I have made a small pocket coil for shocking. The core is a bundle of soft iron wires, 3in. long, 5-16in. diam., wound with about an ounce of No. 36 silk-covered wire as primary, with no secondary at all. Now I should esteem it a great favour if Mr. Bottone would give me dimensions and a few hints as to construction of a pocket battery suitable for working the above. Chloride of silver cell is too expensive. I tried it with a Leclanché cell with porous pot 6in. high; the effect was very slight. I then coupled this in series with a plate of copper about 2in. square and one of zinc about 2½in. square, dipped in a pot containing hydrochloric acid and water, and the coil worked famously. I should also be glad to know if copper can be used instead of carbon (which is very hard to cut) in a sulphate of mercury cell. —Rouge Gorge.

[60857.] — **Electro-Plating and Coppering.**—Will some experienced fellow-reader help me with the following difficulties? (1) How to doctor a silver solution that has lately deposited a coating (especially on g.s.) that is very liable to strip with burnishing? It deposits freely and a good colour. (2) How to prepare carbons so that the copper will adhere firmly? I find that sometimes it holds like "grim death," and at others I can almost wipe it off. (3) How, with a certainty, to get a bright deposit of copper from an alkaline solution of copper on steel goods?—In a Fix.

[60858.]—**Income Tax.**—I lent a person £100 at 5 per cent. on a deed of mortgage on his house. The person, on paying me the interest on the last occasion, produced the receipt of his last payment of Income Tax on this house, and demanded payment of the same from me, saying that it was my place to pay the Income Tax on the property for which I held the deeds. As I do not pay Income Tax, not having the necessary income, I denied my liability. Is there any new law which compels a mortgagee to pay the Income Tax on the mortgaged property?—C. J. W.

[60859.]—**Weight of Modern Steam Ships.**—Perhaps some of the readers of "ours" can tell us what is about the percentage of dead weight, meaning thereby the weight of hull and machinery, to the total displacement, in the large modern iron and steel steamships. — St. Aubyns.

[60860.]—**Turbines.**—In Cullen's "Turbines," published by Spon, I find the following anomalies in the formulæ: On p. 32, Q is the quantity of water in cubic feet per second, H height of fall in feet, P H.P. of the water at 75 per cent. $= \frac{Q\,H}{700}$; but on the opposite page it is distinctly stated that "the cubic feet of water per min., multiplied by the height of fall, and divided by 700, will show by the quotient the power of the wheel." Again, on page 33, in a note, $A = \frac{Q \times 60}{2\cdot08}$ for falls under 38ft., notwithstanding in the example worked out for a 9ft. fall, the formula used is $\frac{Q \times 60}{\sqrt{H} \times 2\cdot08}$. In one place r is given as $D \times 3\cdot6$; in another $d \times 3\cdot6$. Will any gentleman who has had occasion to consult the work for practical use tell me if he has noticed these and any others, and what course he has adopted in connection with them? My copy is dated 1871. I have written to the publishers, who have in turn communicated with the author; but have received no reply.—W. J. Taylor.

[60861.]—**Wind-wheels.**—A paper appeared within the last three years giving a description of modern American practice in the design of wind-wheels and windmills. I saw it in one of the English technical journals; but have not succeeded in finding it again. Can any reader kindly give me the necessary reference?—Q.

[60862.]—**Parallel Motion.**—I have the care of a Cornish pumping engine; cylinder, 84in. by 120in., with motion working very badly, vibrating towards centre of beam at each stroke. Will some kind engineer say if the following lengths of motion are correct? From centre gudgeon to piston links, 16ft. 6in.; centre gudgeon to motion links, 9ft. 2in.; from motion links to piston links, 7ft. 6in.; radius rods, 11ft. 2in.; parallel rods, 7ft. 6in.; links, 5ft.; brasses in good condition.—C. Ensor.

[60863.]—**Legal.**—Thirteen years ago, I bought three cottages with gardens, which are parted from another by a hedge. I have the plan on some old deeds, which shows the hedge belongs to me. My tenants have been accustomed to cut it. The adjoining garden has been sold, and the purchaser has dissuaded my tenants from cutting it, saying it belongs to him. I don't much care about the ownership; but he wants the hedge to grow up to hide the view of my cottages, which will shade the sun from my gardens. Will some kind friend say if I can cut it?—C. Ensor.

[60864.]—**Gas Products.**—In a small private gas-works here, am often troubled with an accumulation of tar, soot, &c., in the standpipes between the retorts and hydraulic main. The material used is Scotch Cannel coal. Shall be obliged by reply stating cause and remedy.—Robert Penny.

[60865.]—**Mathematical.**—Will some kind reader explain what is meant by a value passing through $\frac{1}{0}$, from $-\infty$ to $+\infty$, or from $+\infty$ to $-\infty$, and illustrate by a simple example?—H. B.

[60866.]—**Equatorial Pedestal.**—I am constructing a 4½in. Newtonian reflector, which I wish to mount equatorially. I have completed tube, both axes, bearings, &c.; but do not know what to use for a pedestal. Would it be best to make it of wood, or to use an iron drainpipe, the R.A. axis being 10in. long? I see Webb advises an iron pipe for an altazimuth stand; but I do not know how I could adapt it to an equatorial. Also I should be glad to know what weight I should make the counterpoise, the Dec. axis projecting about 10in., and the telescope, with mirror, &c., weighing 28lb. Will some fellow-reader kindly help me over these difficulties?—S.

[60867.]—**Photographic.** — What is best way to remove stains of developer from fingers, which seem to me worse than the old nitrate of silver stains to accomplish? —W. K.

[60868.]—**Numbering Stamps.**—I have one with revolving brass wheels, also ink; but the latter has got wrong (?) by age. It is not apparently sufficiently fluid, nor does it dry quickly enough. Can I add anything to that in the bottle to make it do so, and, if so, what, and how much?—W. K.

[60869.]—**Twin Screw and Paddle Engines.**—Will any correspondent be kind enough to give me information as to the advantages of twin screw and paddle engines (disconnecting and otherwise) over the ordinary kind?—Twin Screw.

[60870.]—**Horse Hair.**—I have a quantity of horse-tail hair. Would any reader kindly inform me how to make rope hair of it?—W. F.

[60871.]—**Coir Yarn.**—I would feel greatly obliged to any reader who would inform me how to bleach coir yarn or coco fibre?—W. F.

[60872.]—**Wooden Chucks.** — Will "O. J. L.," or some other reader please tell me which way the grain of the wood should run in making each ordinary wood chuck in box, beech, oak, and ash? Which is the best wood to turn some speed pulleys out of for a 3in. lathe? Should the gut band fit all three speeds?—W. M.

[60873.]—**Business done in the Dark.** — Will some kind reader inform us if it is legal to bar reporters during our local board sittings, and does not the arrangement come under Sir Benjamin Hall's Act? If so, where could the Act be obtained, and the price? I may say we have petitioned the board with a great number of signatures, praying for the admission of a reporter, which was refused.—Daylight.

[60874.]—**Dynamo.** — I have two bobbins, each of which is wound with ½lb. of No. 20 wire, 2in. by 1¾in., with ½in. cores. Can they be made into a small dynamo to light a 2½c.p. lamp? If so, please give dimensions of cores, armature, wire, &c., and the power required to drive: I was thinking of using cores of Gramme form, also armature of U-shaped pieces of sheet copper, arranged in a circle on spindle, insulated and channel wound with iron wire, and the legs afterwards connected with copper strips, the whole forming a ring armature. If this form is suitable, please give hints on construction and mounting. If preferable, I can have the cores forged.—T. S.

[60875.]—**Small Medical Coil.**—To Mr. Bottone. —I have made a small medical coil with a brass flange on the outside over the iron core to keep it in the centre. Does that make any difference to the vibrating of the spring, as mine will only work for a few seconds? When the tube is out, with two bichromate cells I get very little shock.—Fixture.

[60876.]—**Bottling Cement.**—Would some correspondent kindly give the recipe for a bottling or capping cement, which is composed of gelatine, glycerine, &c.? It is said to be very tight and very clean in use. I believe it was in your very useful paper where I saw it a long time ago; but I can't find it in any of the back numbers in my possession. Mine are not bound, so it is easy to miss it.—Ajax.

[60877.]—**Finishing Cast Steel in the Lathe.** —Would some correspondent kindly explain the proper way to finish best cast steel in the lathe? I have asked several turners, and got different answers from some of them. One said it ought to be finished dry, because soap-water and oil, by putting a skin on, quickly rubbed cutting edge off tool. Another said it should be done with soap-water, and the other preferred oil. Who is right?—Apprentice Turner.

[60878.]—**S.E.R. Locos.**—Would some railway contributor kindly send sketch and dimensions of No. 247, built by Atlas Works Co., and also No. 205?—H. I. W.

[60879.]—**Test for Field Glasses.**—Is it a good test for field-glass to see the blue companion to bright star in centre of Pleiades?—W. T.

[60880.]—**Boiler Supply.**—Can any of our readers say if there is any objection to the following plan to supply kitchen boiler with water? I propose to connect supply-pipe from main direct to underside of boiler (wrought-iron one), and then connect a pipe to top of boiler and lead it to scullery immediately behind. I would have a tap on supply pipe, so that I could shut off if necessary.—Dick.

[60881.]—**Pitch-Pine Stopping.**—Can anyone give information how to make a good stopping for above?—G. H. H.

[60882.]—**Model Gas Engine.**—I want to make a very small gas-engine, as my tools will not allow me to go in for large work. What are the dimensions of the very smallest gas-engine I may expect to work, providing it should be well made?—Watchmaker.

[60883.]—**Building Amateur Workshop.**—Will someone kindly advise on this subject? I am thinking of buying a second-hand iron building large enough to take two or three lathes, gas-engine, bench, &c. Would like it of oblong form. Presume it must be lined with wood inside. What distance should the wood be from the iron, and what filling should be used? Should I be likely to suffer more from rust than in the house? What would be the probable size required, and the cost? Would the floor be strong enough to take a 2-man engine without vibration, or should I have to cut away same and fill in with concrete? What height should the floor be off the ground, and must it stand on a brick foundation?—Amateur Tinker.

[60884.]—**Textbook of Mechanics.**—Can any of our readers recommend me some practical handbook, giving explanations of the functions of the more ordinary machines of an engineer's workshop, as lathes, planing machines, shaping-machines, &c. I have the appliances of a workshop at command, but feel the difficulty that

besets most amateurs—the want of that experience in the handling of these appliances, which his professional training gives to the regular engineer. I understand, of course, that skill of hand cannot be given by any book; but I should like to obtain, if possible, some work written for the guidance of workmen, and detailing the various combinations and characteristics of the machines—what they will do and what particular risks to beware of in handling them, so as to minimise as much as possible the necessity of having to do a piece of work more than once through inadvertently spoiling it.—An Amateur.

[60885.]—**Scissors Grinding.**—I have a 5in. emery wheel in hand lathe, and should like to grind the family scissors. Will someone kindly give me directions how to proceed?—Country.

[60886.]—**American Lever Timepieces.**—When the balance staff has dug enough in the bottom of the holes in which they run (made in steel screws hardened) to bind, how do you get the shape of the sinks back to the right angle?—Country.

[60887.]—**Enamel.**— I have a quantity of tinplate reflectors or shades for lamps, and I wish to enamel the same with white enamel. Will someone kindly give me a good recipe?—Pro Bono Publico.

[60888.]—**Achromatic Lantern Objective.**—I should be glad if some kind correspondent would furnish me with particulars for making the above to work at three different distances. With the shapes, diams., foci, positions, and distances in the tubes, and kind of glass used. I am quite able to fit up the tubes and rack and pinion work; but I cannot find in any of the back numbers sufficient information to work upon.—H. G. R.

[60889.]—**A Good Battery.**—Will Mr. "Cato" kindly oblige with details of the battery of which he wrote in last week's English Mechanic, Nov. 5th?—Peregrinus.

[60890.]—**Master Keys.**—Will some of "ours" explain the principle of these as applied to lever locks (an illustration will oblige)? Also the derivation of the word padlock?—H. H.

[60891.]—**To Mr. Bottone or Others.**—Could you tell me, if possible, what the battery boxes (of the G.P.O.) are insulated with inside?—Young Electrician.

[60892.]—**Annuity and Estate.**—Will some kind friend give me the present value of an annuity £115 with 32 years to run? Also the value of a freehold estate whose annual rental is £65, with working of the same?—W. R. L. R. N.

[60893.]—**Cement.**—A pot, or earthenware pipe (trap of w.c.) fits into end of thin sheet-copper pipe about 5in. diam. Will some reader please say what cement is used to make joint water-tight?—H. H.

[60894.]—**Varnish Brush.**—Will any reader inform me how to clean camel-hair brushes after using them in hard drying spirit model varnish? Have tried turpentine, but it does not answer.—H. H.

[60895.]—**To Mr. Bottone.**—I am making a Gramme dynamo, as described by you on p. 590, Vol. XLI. Armature is a malleable casting. Pole-pieces are ordinary cast iron, and F.M.'s made from 1½in. round annealed iron, screwed into pole pieces. Armature is wound with nearly 3lb. No. 18 d.c.c. wire in eight sections, three layers each, as two sections was under 2lb. of wire as stated. You gave 6lb. of No. 16 for F.M.'s. Is this for arc or incandescent? I want to light as many 20c.p. lamps as possible. Please say the quantity and size of wire required if shunt would be better. I want to run it as a motor occasionally.—W. P. W.

[60896.]—**To Mr. Bottone.**—I am making a coil with regulator to both circuits, as described by you in "Ours" lately; but can only get about ½lb. of primary on. I have wound it very evenly and tightly, and in four layers. Is this enough? Would the spark be improved by adding a condenser, with a switch to disconnect same when being used for shocks? If so, please say how many sheets and size.—W. P. W.

[60897.]—**Fire Engine Boiler — Shand and Mason's Patent Inclined Water-tube Boiler.**—Can any of our numerous readers kindly give me a description (with small sketch) of the above—the number of tubes and how fastened in the material used for the fire-box? and kindly state how the joints of the shell are made steam tight. I am given to understand the outer shell is movable and bolted on. Is sheet asbestos used for the joint?—H. R. W.

[60898.]—**5in. Gregorian.**—I have been making a 5in. Gregorian telescope, and now that I have put the mirrors in their places, I cannot get an image through the eyepiece, although when eyepiece is removed a very well-defined image can be seen in front of the small mirror. The mirrors are respectively 31in. and 5in. focus, and I have put them 36in. apart, and can move them from this 2½in. either nearer or further, but with no better result. Will someone tell me where I am wrong, or suggest?—Perplexed.

[60899.]—**To Chemists.**—Will any reader of "ours" please give the equations which go on in the reactions between (1) nitric acid and iron, (2) iron sulphate and potassium bichromate?—Joel, Ebbw Vale.

[60900.]—**Highland Ry. Loco.**—Perhaps someone will be able to send a sketch and dimensions of this engine, which was exhibited at Edinburgh Exhibition. It would be interesting to have a drawing of it, as sketches of the other engines exhibited there have been already given.—Amateur.

[60901.]—**Gas-Engine.**—How does the ignition take place in Dorrington's Amateurs and Little Compact gas-engines? Is the slide in the former worked in the same way, or by an eccentric? Will they both work with benzoline gas and Fletcher's generator?—E. R. Dale.

[60902.]—**Gas Furnaces.**—Having been rather successful with iron and brass founding, with the blowing machine illustrated in Vol. II. *Journal* of the A.M.S.; but now, not having access to the furnace, I use a generator 14in. by 9in. by 9in., a Fletcher furnace 5in. by 5in., and foot-blower about 10in. by 8in. It is very hard work. I have broken two cast-iron treadles. I also find the wire rusts, and then the net, and breaks, and the rubber bursts, and it is with great difficulty I can cast at all. Is my blower too small? I want to melt iron, &c., as I make chucks for lathes, &c.—E. R. D.

[60903.]—**Motions of Earth and Moon.**—In Encyc. Brit. (Astronomy, p. 797, first sentence), I find the following: "The earth in reality revolves in the course of a lunar month, around the common c.g. of her own globe and the moon's." It is further stated that the diam. of this orbit for the earth is 6,000 miles. Are these statements correct?—J. C. O.

[60904.]—**Lilium Auratum.**—Can any reader tell me whether it injures the bulb to allow, say, one pod of seed to ripen on a stem which was strong enough to carry 12 large flowers, or whether it is better to cut off the seed vessels as soon as the blooms fade?—Hortus.

[60905.]—**Induction Coil.**—Will anyone say, in making a coil to give 1in. spark, if it is any advantage to use a dividing disc? If so, what should be (1) the diam. of a core 7in. long, (2) the insulation between layers, (3) the size of condenser, and (4) the battery power employed?—Scottie.

[60906.]—**Lens.**—Will some reader kindly advise me in the choice of a lens suitable for taking animals (dogs, &c.) in the open air with instantaneous shutter? Would such as Wray's 5 by 4 of 5¼ back focus, which works with $\frac{F}{5\cdot65}$ stop, be suitable, or would it be necessary to work too close to the object in order to get it large enough on the plate, as I want to get a moderate-sized dog large enough on 5 by 4 plate at 8ft. or 10ft. distance?—Enquirer.

[60907.]—**Incubator.**—In Vol. XXXIX., No. 1009, letter 45063, Gerard Smith gives drawing of incubator. Would he kindly give distance between bottom of tank A and perforated bottom of wood L, and oblige?—T. P.

[60908.]—**Boiler.**—Will some of your kind readers of the "E. M." give me some information on the above? I am about to try to make a model engine boiler, horizontal (slide valve cylinder for same), 6in. diam. by 16in. long, with internal fire-box, if possible. I want to know how I must proceed to make the above. Would cylinder tin or sheet copper be best, and riveted or soldered be strongest for it? Also, what amount tubes, and size, would it require if necessary? Also, as to mode of fire-hole, and what would be the amount of steam this would work with safety? Also, size of cylinder most suitable. A reply or any other information on above would greatly oblige.—A New Beginner.

[60909.]—**Mangle Rollers.**—I have a wringing machine, of which the above are working loose on the shafts continually. I have tried various things to fasten them, but have so far failed to do so. I should be glad of advice from some reader of the "E. M." to give me some remedy for above. Is there not a cement that I could run in the centre hole of rollers? By so doing would greatly oblige.—A New Subscriber.

[60910.]—**Screw-Cutting.**—In an article on "Screw-Cutting Apparatus," in No. 1097, "O. J. L." promised your readers to give a description of an "entirely novel contrivance for tracing screws," and of which he hoped very shortly to send a fully-illustrated description, already written, but delayed at the maker's request while erecting some necessary machinery for its manufacture. I, and doubtless others of your readers, have been anxiously looking for the description in question. When may we expect to see it?—E. T. B.

[60911.]—**Steam-Engine.**—Could any of our friends kindly give me a little information? I want to cut off steam sooner in the stroke of engine. Is it possible to be done by shifting the eccentric on the shaft? I shall be thankful for full particulars through the Mechanic.—Slides.

[60912.]—**Dividing Brasses.**—Would someone kindly give the construction for finding the correct angle at which to divide the brasses of a horizontal engine, so as to get the division at right angles to the wear?—Brazen.

[60913.]—**Cheap Dynamo.**—Would Mr. Bottone or some other kind reader tell me the way to make a good, cheap dynamo, one that would light five 20c.p. lamps, and the best way to drive it? Would an electro-motor do?—C. Gunn.

[60914.]—**Writing Ink.**—Would some one advise what chemicals to use to prevent ordinary writing ink from turning brown or rusty? Why are roasted galls used by the trade for the manufacture of copying ink? I have heard they contain more tannin after roasting, and consequently make a stronger ink. If this is so, does this also apply to myrabolams?—O. J. K.

[60915.]—**Tannin.**—How can I tell when I have a 5 per cent. solution of tannin? What is the simplest method of estimating the amount of tannin in different materials?—O. J. K.

[60916.]—**Daniell's Battery.**—I am making some Daniell's cells, size of boxes inside 8½in. by 6in. square, porous pots 2½in. by 9in., corrugated copper in outer cell, and rod of zinc in porous pot, with the ordinary solutions. I want to know roughly, as I do not understand electrical measurement, how many of these I should require to light two 5c.p. lamps. Also, are the red porous pots the best for this kind of battery?—T. C. S.

[60917.]—**To Mr. Wimshurst.**—I am thinking of making one of your eight-plate influence machines. If you will answer me the following questions I should be greatly obliged. Should the dust-proof case have glass or wooden top? What is the right thickness for the discs—will 15oz. do? Will mahogany handles do in place of vulcanite for the terminals? Will thick brass wire heavily covered with shellac do instead of guttapercha for the collecting combs?—J. R.

[60918.]—**Screw Cutting.**—Will any brother reader please assist me in the following:—I have a 4½in. centre screw-cutting lathe, with four threads per inch, leading screw when cutting screws of odd pitch, such as 5, 7, 9, and so on. I cannot make the saddle gear with the leading screw to bring the tools right for the second cut. If any one will explain this it will greatly oblige.—One in a Fix.

CHESS.

All Communications for this department must be addressed to J. Pierce, Langley House, Dorking.

PROBLEM MXVII.—By E. N. Frankenstein.

NOTICES TO CORRESPONDENTS.

Correct solutions to 1,015, by F. Kraser (a splendid problem) and J. Mackenzie; to 1,016, by Black Pawn, J. Mackenzie; to 1,014, by A. Bolus.

A. Dean.—We trust that our reply to your letter was found satisfactory.

A. Bolus.—Many thanks for the two problems.

We are open to receive names of competitors for two Solution Tourneys to be started shortly on similar lines to the last, as they were so successful. Tourney A will consist of 8 three-movers and 6 two-movers, and Tourney B of 12 two-movers. The prizes in A (provided there are at least 12 entries) will be 1, £1; 2, "English Chess Problems" (unbound); 3, Taylor's "Elementary Chess Problems" (out of print); 4, Rowland's "Chess Fruits." In B (if 12 entries, at least), 1, "English Chess Problems" (unbound); 2, Miles's "Chess Problems, 1885"; 3, Collins' "Problems"; 4, Gossip's "Chess Openings." The entrance fee in each Tourney will be sixpence, as before, to go towards defraying the cost of the prizes.

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve Months, Post Free to any part of the United Kingdom. For the United States, 13s., or 3 dol. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office Order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. James W. Queen and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the English Mechanic, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII. XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX., XL., XLI., XLII., and XLIII., bound in cloth, 7s. each. Post free, 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post free from the office (except index numbers, which are 3d. each, or post free, 3½d.).

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI., and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

J. THEOBALD & COMPANY'S SPECIALITIES.

THE SKATING SEASON.

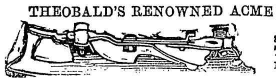
VERY PARTICULAR ANNOUNCEMENTS.
EVERY LOVER OF SKATING SHOULD READ THIS.

Last February we ordered 8,000 pairs of Skates, having previously cleared out all our old stock, so that every Skate we have got in the place is perfectly new. Many shops only buy once in four or five years, and bring out, season after season, rusty skates. The more Skates we can buy the cheaper we can get them, consequently the cheaper we can sell them, and yet there are thousands of persons who will never order Skates till skating really commences, then they are in such a hurry they cannot wait to send to London for them, but rush into the nearest shop, get inferior old Skates, and pay twice or three times as much for them. We want to reach this class of people; we want, if possible, to obtain their custom, and we have therefore hit upon a very novel plan, never before tried with Skates, which we hope will induce them to order directly they read this announcement. With every pair of Skates we intend to give a Free Gift. We make no charge whatever for the Gifts. It is simply done as an experiment on our part to see if it results in our selling sufficient extra Skates to pay for so doing. 500 pairs of Acme Pattern Skates are done up at one time in separate parcels—assorted sizes—and with each pair of Skates is packed up a free gift. The parcels are then securely tied up and the size and kind written outside each parcel. Then, as the orders come for them, they are simply addressed and despatched, no one being able to tell what Prize is in any parcel, so that the distribution is perfectly fair, and every one has an equal chance of getting the very best prizes.

The 500 Prizes put in every 500 parcels are as follows:—5 Silver Watches, 25 Real 9-Carat Gold Rings, 50 Sterling-Silver Scarf Pins, 25 Sterling Silver Brooches, 50 Leatherette Writing Cases, 20 Gold Pencil Cases, 50 Packets of Christmas Cards, each Packet containing 50 Cards, 100 Volumes of Books, 100 Fancy Scarf Pins, 25 Handsome Bracelets, 50 Pairs of Folding Scissors.

As soon as one lot is sold another 500 is done up, and so on.

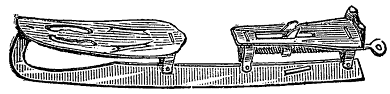
THEOBALD'S RENOWNED ACME PATTERN SKATES.



These are so well-known as to need no description. They are of best Bessemer steel throughout, and are simply secured to the feet by means of nuts and screws. Once the Skate is properly adjusted to the boot, it can be put on or taken off instantly by merely pressing a small lever. With key complete, price 5s. per pair, post free; or beautifully Nickel Silvered, 10s. per pair.

To save any error, please be careful to cut out Coupon and send it with the order.

ACME SKATE COUPON.
Entitles holder to ACME PATTERN SKATES at above prices, including Free Gifts, if ordered within 14 days of the date of this paper.
(Signed) J. THEOBALD & COMPANY.



THE KENSINGTON NEW STEEL SKATES.

These Skates we specially introduce to do away entirely with the old-fashioned wooden Skates, which are now so seldom seen, and which we have given up keeping entirely. The Kensington Steel Skates are now introduced for the first time, and we advise every one who wants a cheap, good Skate, to send for them. They are of steel throughout; strong, well made, with no nut or screw; but by means of turning a little handle at the back, a strong claw, working on a long screw, grips the heel firmly, while a short strap goes across the front of the boot. Price 3s. 6d. per pair, post free. These are NOT supplied nickel plated, but are only made in the one quality. With these Skates Gifts are also given the same as with the Acme Pattern, with the exception that owing to their being a much less price, we are not giving any Watches, and only 20 instead of 25 Gold Rings, the 10 prizes thus short being made up with extra books.

Customers must say exactly what length in inches they require the Skates to be, whether 7½, 8, 8½, 9, 9½, 10, 10½, 11, 11½, or 12 inches long.

All Skates are sent off by Parcels Post per return.

Secure these Skates at these wonderfully low prices, with Gifts free, while they can be had. You stand a good chance of getting a good pair of Skates and a Silver Watch for 5s.

Initials engraved on any Skates at 1s. 3d. per pair extra. Not more than two Initials on each Skate, and this makes one day's delay.

Skates can always be had at above prices while our Stock lasts, but the gifts will only be given to those who order within 14 days of the date of this magazine.

KENSINGTON SKATE COUPON.
Entitles holder to KENSINGTON SKATES at above prices, including Free Gifts, if ordered within 14 days of the date of this paper.

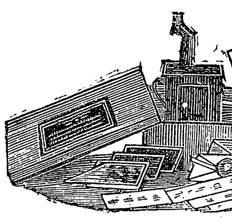
OUR CELEBRATED BIJOU MAGIC

LANTERNS AND SLIDES.



Some people having tried in a feeble way to imitate these Lantern sets, which we have sold in such immense quantities for years past, by copying our description, we have this season altered our Slides, and given such quantities and value for money as defies all competition. We manufacture both Lanterns and Slides, other houses do neither, and therefore cannot possibly sell so cheaply.

Nothing is so amusing, entertaining, and instructive for the long winter evenings as a Magic Lantern, so long as Lantern and Slides are of good quality and show well. This we guarantee in every set we sell. Compare our sets with those of any other house.

Our No. 1 Set contains a best quality English-made Magic Lantern, fitted with best condenser and focussing Lens, best Mineral Oil Lamp, with rackwork adjustment, glass chimney, metal chimney, brass nozzle, with improved ventilation to lantern, slide holder, and silvered reflector, and the following large assortment of slides: 36 comic figures, 3 complete nursery tales, comprising 36 pictures (no other house in the world gives more than 1 nursery tale, as these are most expensive, costing 2s. each), 2 Chinese firework slides, 2 comic moving slides, 2 movable lever slides, 2 moving panorama slides, and 1 revolving slide—man swallowing rats, making 81 pictures in all, and candidly worth a guinea. The complete set, in box complete, 10s. 6d. This set shows pictures 3 feet in diameter.

No. 2 Set, a similar assortment, but both Lantern and Slides larger size, 14s. 6d. Shows 4 feet diameter.

No. 3 ditto, but much larger, a very excellent set for a present, specially recommended, price 21s. Shows 5 feet diameter picture.

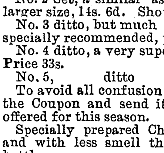
No. 4 ditto, a very superb set, showing pictures 6 feet in diameter. Price 33s.

No. 5, ditto ditto 7 feet, 50s.

To avoid all confusion we earnestly beg every person to cut out the Coupon and send it with their order, as these are special sets offered for this season.

Specially prepared Chemical Oil, showing much more brightly and with less smell than ordinary oil, 9d., 1s. 6d., and 2s. 6d. per bottle.

ENGLISH MECHANIC COUPON.
Entitles holder to SPECIAL SETS OF BIJOU LANTERNS AND SLIDES at above prices.
(Signed) J. THEOBALD and COMPANY.



MAGIC LANTERN

SLIDES for full size Lanterns, all splendidly coloured, 3¼in. square, 12s. per set, any of the following subjects:—Dick Whittington, Elephant's Revenge, John Gilpin, Blue Beard, Tiger and Tub, Cinderella, Crusoe, Gulliver, Views of London, Continental Views, Palestine Views, Life of Christ, Pilgrim's Progress, Overland Route, Arctic Expedition, Life of Joseph, &c., &c.

GRAND PRIZE STATIONERY

PACKETS.
EXTRAORDINARY ANNOUNCEMENTS.

Owing to the immense number of letters we have received every day since last Spring, when we advertised these packets for the last time, asking if they can still be had, we have determined to offer them again for a few weeks this Autumn. Each prize Stationery Packet consists of: A beautiful elegant Crocodile leatherette writing case fitted with compartments for note paper, envelopes, post cards, stamps, &c., also 24 sheets of good superfine note paper, and 24 Court envelopes, elastic band, a pen and penholder, a 4s. copyright song, a beautiful fancy ivorine opera glass for the watch chain, containing a wonderful little magnifying glass and photograph, a good pocket handkerchief, and a packet of 100 puzzles. We offer this entire lot, the most wonderful value for money ever given, for 2s., post free 2s. 3d.

In addition to the above, without any charge whatever, we shall put a free present in every packet. We make up 500 packets at a time, and in every 500 packets we are putting 30 volumes of books, 10 telescopes, 10 microscope, 50 real sterling silver scarf pins, 50 beautiful fancy scarf pins, 10 real gold finger rings, 10 real sterling silver brooches, 20 musical instruments, 10 gold pencils, 20 pairs folding scissors, 20 pocket knives, and the remainder of the prizes consisting of silver watches, paper knives, musical boxes, bracelets, pipes, toys, &c. Thus it will be at once seen that besides getting full value for money, every person obtains a free prize oftentimes of 10 times the value of their money. Please send orders at once, 1 packet for 2s. 3d., carriage free, 2 packets, 4s. 3d., or 3 for 6s.

Money instantly returned if the packets are not according to description. We have numerous letters from persons acknowledging receiving watches, rings, &c., in their packets, and these letters can be seen at our offices. This is a perfectly genuine announcement, as we have been established in Kensington over 50 years, and sold more than 20,000 of these packets last spring.

The coupon below must be cut out and sent with order.

ENGLISH MECHANIC COUPON.
Entitles holder to PRIZE STATIONERY PACKETS at above prices.
(Signed) J. THEOBALD & COMPANY.

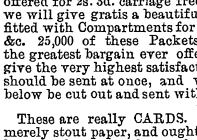
THE GREATEST VALUE EVER

OFFERED BY ANY HOUSE IN THE WORLD.

Kindly study thoughtfully what we guarantee every packet to contain. This packet is the outcome of several gigantic failures of manufacturers, otherwise it would be impossible to sell it at the price. Every packet contains 24 ordinary size Christmas and New Year's Cards with appropriate Mottoes, Flowers, Birds, &c.; 6 magnificent Gold Cards with figures of Children, Animals, &c., in beautiful colours, with Christmas and New Year's Greetings; 6 long Cards of Children dressed for Christmas Parties, with Holly, Flowers, and Greetings; 12 superlative Cards in Gold and Silver Bronze, with embossed Flowers and centre oval of Texts or appropriate Poetry for the Season in gold and colours—each of the 12 cards measures 8in. by 5½in., and are alone worth the value charged for the entire Packet; a set of 6 beautiful stamped out perforated Easel Frames, in splendid colours, with oval mirror containing words—"A Joyful Christmas," "A Happy Christmas," "A Merry Christmas," "A Happy New Year," "Home Sweet Home," and "God Bless our Home,"—and surrounded by an outer framework of trailing Flowers, the prettiest and most unique things ever made; a set of six Cards illustrating different phases in the life of a City Arab, in beautiful colours, and each bearing a Christmas greeting. These studies are taken from real life. In addition to all the above, one 2d. Card, four Cards at 3d. each, and four Cards at 4d. each. All these Cards of New Designs, most chaste and beautiful Flowers, Leaves, &c., in 10 to 20 different colours, with Christmas and New Year's Greetings and Verses, &c., of the richest possible manufacture, making in all a total of 69 Cards. Equal in value to what would cost, in an ordinary shop, about 10s. 6d. The entire lot offered for 2s. 3d. carriage free. To every purchaser of two Packets we will give gratis a beautiful Crocodile Leatherette Writing case, fitted with Compartments for Note Paper, Envelopes, Cards, Stamps, &c. 25,000 of these Packets now ready to be sent off. This is the greatest bargain ever offered to the public, and cannot fail to give the very highest satisfaction. To avoid disappointment orders should be sent at once, and we urgently request that the Coupon below be cut out and sent with all orders.

These are really CARDS. Many of the Packets advertised are merely stout paper, and ought not to be called cards at all. Also, beware of persons who send out cards which they have bought up, for next to nothing, from makers who cannot sell them because they are several years old. Our Packets contain the Newest Designs for this Season, and of the Best Quality.

ENGLISH MECHANIC COUPON.
Entitles holder to CHRISTMAS BOX PACKET OF CHRISTMAS CARDS at above price.
(Signed) J. THEOBALD and COMPANY.



THE FLYING

DUTCHMAN STEAM LOCOMOTIVE. This is the cheapest real steam working Locomotive ever brought out, and is invented and manufactured solely by us. Large metal boiler with four wheels, oscillating cylinder, steam tap, safety valve, steam pipe and furnace complete. Warranted to work. Carriage free, 3s. 3d.

THE SCRIPTURE OPERA GLASS.

A wonderful tiny Ivorine Opera Glass, for hanging on to the watch chain. On looking through it can be read distinctly, by aid of a microscope placed therein, The Lord's Prayer or the Ten Commandments, though neither is larger than a pin's head. Post free, 6d. each. One of the marvels of science.

THE ACTRESS OPERA GLASS. A

wonderful tiny Ivorine Opera Glass for hanging on to the watch chain. On looking through it can be seen distinctly, by aid of a microscope placed therein, the Portrait of an Actress in costume, though no larger than a pin's head. Post free, 6d. each. One of the marvels of science.

GRAND ILLUSTRATED WINTER CATALOGUE, over 500 Illustrations, 60 Pages, post free, one stamp. Novelties of every description, Conjuring Tricks, Chemicals, Clockwork and Christmas Toys, Cards, Games, &c., &c. Special Illustrated Catalogue of Magic Lanterns and Slides, 3d. Special Illustrated Catalogue of Model Steam Engines and Parts of Engines, 3d.

J. THEOBALD & COMPANY,

WHOLESALE MANUFACTURERS (ESTABLISHED OVER 50 YEARS),

6 & 7, Bath Place, Kensington High Street, Kensington, London, W.

ANSWERS TO CORRESPONDENTS.

⁂ *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

⁂ Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, Nov. 10, and unacknowledged elsewhere :—

F. A. COBBUD.—W. Kelly.—Rev. C. H. Cope.—E. Weston.—C. Ashford.—Cuttriss and Co.—E. S. Hindley.—A., Liverpool.—A Fellow of the Royal Astronomical Society.—B.—Midnight Oil.—O. J. L.—Mac.—David.—G. R. H.—Beginner.—San Koe.—Rara Avis.—Amateur.—C. H. C.—Ernesto.—Septo.—H. J. Cress.—Pump.

P. M. (Can you not make a sketch for yourself and see the position it must be in?)—G. P. BEST. (All the information in connection with the City and Guilds Institute is given in the "Programme," which can be obtained from the Director, Sir P. Magnus, Gresham College, E.C.; but as you are so near, why not call at the Finsbury College?)—C. P. HALE. (Hamilton's.)—CHARLTON HALE. (See any textbook of mensuration.)—E. M. G. (We do not think there is any full account anywhere; but Ure's Dictionary has an article on the subject, and so has Payen's "Industrial Chemistry.")—JUGGINS. (A description will be found in No. 1,071, p. 102. 2. Any of the publishers of educational works has one or more in his list. 3. Ditto. See catalogues of publishers.)—A. J. P. (A series of articles on electrical motors and their construction appeared in Nos. 1026, 1027, 1029, 1041; but see the indices of the last six volumes.)—A. B. (No "notice" at all. It must be paid befor the expiration of the fourth year from the date of the patent, as fully explained in the "Rules.")—FAIR PLAY. (The police have no right to enter a house and search without a warrant, unless they have seen a thief, &c., entering it.)—CHATTERIS. (The instructions have been given over and over again. The steel is made red-hot—it is well to look at it in the dark—and is then immersed in water, salt and water, or oil, according to the quality of the metal and the nature of the temper required. It is then brightened in order that the colour of the temper may be seen, and is placed on a piece of red-hot iron. At first it becomes a pale straw yellow, and gradually darker until purple appears, and then blue. A brownish yellow is suitable for chipping chisels, mill picks, &c., the blues for spring steel. When the required colour is seen the steel is cooled off at once in water. In the case of chisels, &c., the smith tempers at once—that is, he heats the steel well, dips the end in water, and watches for the colour to appear from the heat in the shank; then cools.)—ARCHBALD. (*Engineering*, Feb. 5, 1886.)—A LEARNER. (Ahn's or Hamilton's. Any bookseller.) — POOR CLOCKEY. (Neat's-foot oil, purified by means of shavings of lead, and placing in the light. That is, put some bright shavings of lead into the glass bottle containing the oil, and stand it in the sun. This may be mixed with sperm, olive, or a little mineral oil; but when purified, which may be known by its ceasing to precipitate, it should be covered up from the light. If wanted very pure, it should be washed with alcohol, then with water, and finally be filtered through animal charcoal.)—BOOTMAKER. (Logwood and bichromate of potash. See "Scientific News," p. 212, and the indices of back volumes.)—DYER. (You want a coil or a very large battery, and there must be some means of completing the circuit in the shape of a metal plate to stand on.)—BEDFORDIAN. (The storm-glass has been frequently described. It is a thin glass tube 12in. by ¾in. in diameter, about ee-fourths filled with a liquid composed of camphor 2 drachms, nitre 1½ drachm, sal-ammoniac 1 drachm, proof spirit 2¼ fl. oz. Close with a brass cap, having a fine hole in it. It will not be of much use when you have made it.)—PITCH BOILER. (We think not; but there are articles in the cyclopædias.)—YOUNG EINGINIVER. (Why not put on a larger one, or procure one from the makers?) AN AMATEUR. (Terracotta is literally "earth baked"—that is, kiln-baked clay.)—SUBSCRIBER. (Out of print, but the makers supply a description.)—WANDSWORTH CHIP. (Nothing to be alarmed at; but take a walk after supper if the dreaming prevents refreshing sleep.)—ELECTICITY V. (No premium at all, we should think, with your qualifications. You should advertise for a situation, saying that you have served an apprenticeship to a mechanical engineer, and are well up in magnetism and electricity.)—NELLIE. (If it is mange, rub in a mixture of black sulphur, lard, and a very little lime. Carbolic soap would be a good thing to wash the dog with, and might avoid the necessity for using the sulphur dressing.)—STEPHEN. (The receipts in question are no doubt as useful as the preparations themselves.)—F. WRAY. (The only way is to make it red-hot in the furnace, and then cool as slowly as possible—*e.g.*, by covering up the fire and allowing it to die out.)—J. C. O. (On the contrary, we did not answer in the way you say, nor was the present the question put. See p. 297, No. 1028. The centre of gravity of the earth and moon is usually taken as 2898·5 miles from the centre of the earth, and the moon revolves round that point once a month. As you now ask a definite question—whether a certain statement is correct—we insert the query.)—DEAN AND CHAPTER. (We think you will find an answer in this week's Replies.)—TOP DRESSING. (Procure some of the manuals by R. S. Burn, published by Crosby Lockwood and Co., Stationers' Hall-court, E.C.; Denton's "Agricultural Drainage," published by E. and F. N. Spon, 125, Strand, W.C.; and Tanner's "Elementary Lessons," Macmillan and Co., Bedford-street, Covent-garden, W.C.)—BRIXTON. (Plaster of Paris, Keen's cement, or fresh-burnt lime mixed with white of egg. See No. 1060, p. 442, and the indices.)—STUD. (They cannot be recast, but the soft vulcanised rubber can be mixed with fresh rubber and sulphur, and re-vulcanised.)—A. E. C. (Apply to the secretary or manager of the company. We know of no examination.)—A. H. M. (You cannot appoint a "qualified substitute" and leave without the sanction of the managers.) JOHN MERRY. (It is impossible to say whether any book will be of service to a given reader without knowing something of that reader's capacity. 2. Simply an effervescing drink resembling "sherbet," except that the tartaric acid and carbonate of soda are kept separately in solution. It certainly will injure a "weak stomach.")—SCIENENTIA. (We are not aware that there is any periodical published dealing with such matters, but there are several scientific journals and magazines which deal with various branches of natural history.)—READER OF "E.M." (We know nothing of it, and cannot understand your description. Why waste your time over it?)—G. A. W. (Apply to Messrs. Shepherd, Rothwell, and Hough, Oldham, for a list of their machines.) — GLAM. (Fine emery might answer; but why will not ordinary fine sand do?)—D. D. (See pp. 52, 533, Vol. XLII., for instance, and the indices of the back volumes.)—DELTA. (See p. 50, Vol. XXXVIII. Don't buy a second-hand microscope unless you have the opinion of an expert or can test it yourself. See indices of back volumes.)—ANNOYED. (How will it answer when your dearest friend knocks at the door? However, you will find sufficient information repeated many times over in back volumes. If one wire is connected to the handle and the other to the knocker, anyone holding both at same time will complete the circuit.)—R. H. W. (As good a preservative as anything is made by boiling 1½lb. of whiting and 1lb. of soft soap in about a pint of water, stirring in 2oz. of dried and finely-powdered chloride of lime. That mixture is rubbed into the skin, and the feathers are dressed with an alcoholic solution of corrosive sublimate, which is too strong if it leaves a whiteness on a black feather when dry.)—E. F. FLEET. (A number has been sent you containing directions for making a Wimshurst machine, and if you refer to back volumes, or to the little book mentioned on p. 193 ante, you will have all the details needed. If you wish to understand all about "Electricity" you should procure Sprague's work on the subject, which is published by E. and F. N. Spon. There is no "practical" book in the sense you appear to mean.)

⁂ It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions and in cases where the amount sent exceeds One Shilling, the Publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O.'s.

The address is included as part of the advertisement, and charged for.

Advertisements *must* reach the office by 1 p.m. on Wednesday, to insure insertion in the following Friday's number.

OUR EXCHANGE COLUMN.

The charge for Exchange Notices is 3d. for the first 24 words, and 3d. for every succeeding 8 words.

Good Value Offered (cash or instruments) for all kinds of sound or repairable Scientific Appliances.—CAPLATZI, Science Depot, Chenies-street, near British Museum. Established 1862.

Wanted, **Photo Apparatus**, wet or dry, cameras, sundries, &c., in exchange for Microscopic or Magic Lantern Slides.—Apply, PIGGOTT, Chemist, Huddersfield.

Commercial Self-inking **Printing Press**, new specimen of work sent with woodcut of machine, cost 50s. Exchange good Set of Drawing E. Instruments, about same value.—C. CAMPBELL, 483, Springburn-road, Glasgow.

"**English Mechanic**," 500 numbers, from 593 to 1093, with indices, clean and perfect. What offers in exchange?—STUBBIN, Buckshorn Oak, Alton.

Will exchange 30-c.p. **Dynamo**, Jones' laminated armature, Thirlmere water motor, 3 pulleys, flywheel, for good lathe or set of leads for light.—151, High-street, Chatham.

Lathe, 5in. centres, all iron, good condition, compound slide rest, overhead gear; offers to £6, part cash preferred; particulars, stamp.—17, Newland-street, Kettering.

"**Knight's Mechanical Dictionary**," first 18 parts, quite new, cost 2s. each. Will exchange for Engineering Books, cash, or offers.—T. BATCHEN, Inness-street, Inverness.

What offers for good **Steam Gauge**, 60lb. pressure, no use to me; cost £3 when new. Would take good Watch or anything useful.—C. HOLDER, 59, Ablow-street, Wolverhampton.

Homœopathic Medicines.—Popular Books on the Science exchanged for Medical Coils by the Medico-Botanical Gardens and Free Dispensary Company, Lydney.

"**English Mechanics**," Dec. 1881 to Aug. 1886; Lancaster Photo Lens, stops, instantaneous shutter, Eclipse. Exchange Electrical, or old large Camera.—FELL, Market Rasen.

Wanted 6in. **Gap Lathe**, with back-gear, centring, and other chucks, surface-plate, and tools; also bicycle rim bender. Offers.—W. B., Spencer-place, Blackheath.

Will exchange 9 Patent **Pens** that will write numbers of letters without taking from paper, and sold at 2s. each, for Opera Glass or Telescope.—R. SAUNDERS, Willenhall.

English Concertina, 48 keys, in mahogany box, by Dawkins, cost 4 guineas; offers to value 25s.—BLANCHARD. No cards.

Diamond Drills for china, glass, stone, &c., the same as used by china riveters. Offers. Stamp reply.—C. BLANCHARD, 29, Earl-street, Lisson-grove, London.

15 **Carbon Plates**, 8 by 2½; 7 Zinc, 6 by 2½, binding screws on all; small motor; 5 c.p. lamp; 2½in. electric bell; 6-cell Bichromate, 2C., 1Z., with lifting arrangement; 20 round, 16 flat porous pots; about dozen binding screws; "Sprague's Electricity." Wanted, mahogany bagatelle table, music type, or offers.—G. R. KING, Newport, I.W.

Six ton **Weighing Machine**, in good condition, lever 4ft. long. Part cash and exchange.—F. GRIFFITHS, Heath Town, Wolverhampton.

Photographic.—Contents of amateur studio, nautical sextant, magneto-electric machine, orguinette, double breechloader, bicycle, grandfather's clock, powerful Singer sewing machine. Offers requested.—A. GARRETT, Towcester.

Wanted Second-hand **Poppett Head** for lathe, 5in. or 5½in. centre. Exchange 4in. Poppett.—NEISH, Burghead, Elgin, N.B.

"**English Mechanic**," Vols. XXXVII. and XXXVIII., for Microscopic Slides, stained or injected.—JONES, Duke-street, Settle.

Vertical Engine, 4in., price £3 10s., or would exchange for old brass, copper, or anything useful.—J. L. GREENWOOD, 7, Dutton-street, Cheetham, Manchester.

Photographic.—Half-plate or larger lens wanted; will give 12in. plate electric machine, or small electro-motor, suitable for driving sewing machine.—B. D., 40, Sandbourne-road, Brockley, S.E.

Eight Iron Lalande **Copper Oxide Cells**, complete, 16 by 8 by 4, with three five-candle-power lamps, and 20lb. of copper oxide. Exchange for Photograph Apparatus.—F. HUDSON, Battle, Sussex.

Wanted, two **Bichromate Batteries**, glass bottles shape, complete, in exchange for new nickel-plated Bull-Dog Revolver, very handsome.—B. TAYLOR, Milbourne-street, Blackpool.

Tricycle, for Piano, double driver, front steerer, hill-climbing gear, buffer saddle, cradle spring, cost £25, lamp complete.—W. W. EVERS, Wath, Rotherham.

Wanted **Double Magnet Battery**, with multiplying wheel, all complete. Exchange "Cassell's Technical Educator," 26 6d. parts, complete, unbound; 24 6d. parts "Popular Educator," unbound, latest edition.—W. BEVINGTON, Alder-lane, Hindley-green, near Wigan.

Wanted, good powerful **Shocking Coil**, suitable for parties or bazaar. Will give good value in other Electrical Apparatus.—T. MORRELL, 54, High-street, Brierley-hill, Staffs.

Model Engine, horizontal 1in. bore, 1½in. stroke; wanted one smaller. Magic Lantern, with 12 framed slides, showing picture about 3½ feet.—Below.

Model Schooner, 30in. long, wanted cutter about 18 inches, or offers for above.—MEIKLE, 100, West Bow, Edinburgh.

Tricycle, Coventry lever, double steering, two track, adjustable pedals, cushioned seat, good condition, newly painted, Offers.—FORD, 75, St. Paul's-road, Camden, N.W.

"**Scientific American**," in weekly numbers, for years 1882-3-4, four numbers missing. What offers?—F. WEBBER, Curzon-street, Nottingham.

4 Horse-power Horizontal **Steam Engine**, in good condition, with governors all complete, part cash and useful exchange.—F. GRIFFITHS, Wednesfield Heath.

Tricycle, nearly new, part exchange; also 50in. bicycle, nearly new, Bown's ball bearings, cowhorn bars.—F. GRIFFITHS, Wednesfield Heath.

Wanted S. Bottone's new book "**The Dynamo**," in exchange for "Shelley's Workshop Appliances," quite new.—Address, JOHN RIGG, 26, East Hope-street, Glasgow.

Wire, Bell, and Mercury, for Back Numbers "E.M." or Books.—To correspondents who wrote to WALTERS, 25, St. Paul's-place, Canonbury, about this. See advt. Exchange, Oct. 29th. Letters accidentally miscarried. Please write again.

Whole-plate Folding Mahogany **Camera**, rising front, two dark slides, single and double, Terebour's Cabinet Lens, Tripod, Background on roller, printing frames, ¼ to whole plate, Glass Bath, and dippers, in case, Cabinet of Chemicals, two large Porcelain Dishes, Mounts, and Graduated Measures. Cost £20. Exchange for Tricycle, or £5 and Electrical offers.—T. A. CARTER, Electrician, Uttoxeter.

Electric Machine, 12in. cylinder, mahogany stand, almost new, packed, £1, or offers.—M., 99, High-street, Gosport.

Thirty back numbers "**English Mechanic.**" Exchange for others I have not got.—M., as above.

6 "**Illustrated London News**" volumes, well bound, and perfectly clean, carriage paid. Useful exchange.—HARRY B. SAUNDERS, Baker, Stoneham-street, Coggeshall, Essex.

Water Motor, half horse-power. Exchange for 20 candle-power Dynamo.—9, Queen Anne-street, Stoke-on-Trent.

Back-geared **Lathe**, 6in., 5ft. bed, 7 speed wheel (gut), Boiler, 2ft. high, with fittings. 12in. Slide-rest. Offers.—Letters, W. SMITH, Bilston-road, Wolverhampton.

Wanted, good **Carpenter's Tools** or Microscope in exchange for 21 2s. numbers "Cassell's Illustrated Travels," nearly new.—S. MASON, 68, Vauxhall-road, Gloucester.

Wanted, Astronomical **Telescope**, good maker and condition, 3 inches or upwards. Exchange Humber Tricycle, Hearson's Incubator, Books, Aurephone.—T., 15, Upper Leeson-street, Dublin.

Electric Bell, 4in., 3-cell battery in box, indicator 6 holes, 6 china pushes, 1 barrel push, all new. What offers?—M., 11, Victor-road, Holloway, London.

Bicycle, 52in., good, no rubbish; exchange for Lathe or Engine, or useful Tools.—GLOVER, 12, High-street, Derby.

Will give in exchange 60 complete numbers of "ENGLISH MECHANIC" for Pigeons, or what offers?—G. T. JAMESON, 24, Gwynne-road, High-street, Battersea.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
FRIDAY, NOVEMBER 19, 1886.

NOTES ON THE CHAMBER ORGAN.—VIII.

By George Ashdown Audsley, F.R.I.B.A.

In the present article I bring my Notes to a conclusion for the present, and, while penning my last remarks, I cannot help expressing a sincere hope that what I have said on the subject under consideration may be the means of inaugurating a more satisfactory system of Chamber Organ building than that which has hitherto obtained. My special thanks are due to the Editor of the English Mechanic for the prominent position he has accorded to these articles in the pages of his valuable journal, and to the many readers who, both publicly and privately, have expressed their kind approbation of my humble attempts to advance the art of Chamber Organ building.

The Touch of the Organ.

The touch of the Chamber Organ is a matter worthy of most careful consideration; for on it depends, to no small degree, many refined effects and certain minute shades of expression. Extreme lightness of touch is desirable in the manual keys, combined with perfect taughtness of all the attendant mechanism or action, and, accordingly, instantaneous speech and faultless repetition in the pipe work. The action must be so accurately adjusted that the pipes speak properly when any key is depressed the thickness of its ivory. The touch should never be heavier than that usual in a grand pianoforte; indeed, for more than one good reason, the pianoforte touch should be imitated as closely as possible in the uncoupled claviers. In most cases the Chamber Organ will be played by persons accustomed also to the pianoforte, hence the desirability of having the touch of both instruments similar. A light touch is readily secured by the adoption of either the pneumatic tubular or the electric actions; but, for general purposes, I recommend neither of these for such an organ as has been contemplated in the foregoing articles. Putting aside their cost and other considerations, not necessary to be mentioned here, there is an objection to anything of so *absolute* a nature. I mean by the term *absolute* these peculiarities—the *full opening* of the wind-chest pallets, let the keys be depressed by the fingers in any manner whatever; and the necessity of depressing the keys to their full depth, or nearly their full depth, before any result is obtained. In the case of the electric action, the instant the contact is made by the key the pallet flies open to its *full extent.* It is impossible, in either the pneumatic or electric actions to arrest the pallets at any intermediate point: they must either be *closed* or *fully open.* A lingering, loving pressure of the keys has no modifying effect on the sounds produced when the electric or pneumatic systems are employed; and yet this lingering toying with the keys of an organ, if the organ is properly constructed, has a power which few, perhaps, have realised at its full value. I have known organists—musicians I was going to say—who disputed the possibility of modifying tone by the manipulation of the organ keys, and who almost laughed at the mention of a refinement they could neither produce nor realise. As I have already said, both the electric and pneumatic actions are so *absolute* as to render such a refinement impossible; and in almost all the organs constructed on the ordinary system the key actions are too coarsely made and adjusted to admit of anything beyond a uniform style of manipulation.

I have given some attention to this, as to other matters connected with the organ, and the result of my experience is that for the Chamber Organ nothing is so suitable as a perfectly-constructed lever, tracker, and roller action. When such an action is made by a master hand, of the finest materials, and lightly and accurately regulated throughout, it leaves absolutely nothing to be desired. To prevent loss of power, undue friction, and any objectionable springing or stretching, let the action be as short and direct as ingenuity can devise. The more perfectly the pallet is under the control of, and partakes of, the motion of the key, just as if they were glued together, the better the result aimed at will be. When the entire action is thus responsive, the organist has a new power in the points of his fingers, and it will not be long before he finds it out. I am free to admit that I am now speaking of refinements of touch beyond the ken of organists who derive their ideas from their acquaintance with ordinary organs, and especially those with pneumatic or electric actions; but I believe, so far at least as the Chamber Organ is concerned, nothing can be looked upon as too great a refinement, or as unworthy of the most deliberate attention. It is only in the multiplication of such refinements that a great result is achieved. It is not in great details that a violin by Straduarius differs from one by any ordinary maker.

It will be gathered from the above remarks that I favour the attached claviers, with which the advantageous short and direct action is alone possible; and that I do not, as a general rule, advocate the detached console in connection with the Chamber Organ. With reference to church and concert-room instruments, the case is widely different; refinements of touch, so valuable in a delicately-voiced Chamber Organ, would be altogether useless in large and loudly-voiced instruments in spacious buildings, and under varied acoustic conditions.

The Breath of the Organ.

The bellows have not inaptly been designated the "lungs of the organ"; and, accordingly, the wind which inflates them and gives life to the entire instrument may be spoken of as the breath of the organ. As in the human frame, so in the organ, capacious lungs and an ample supply of air are necessary to its proper functions. An organ can be asthmatical as well as weak humanity; and when so afflicted neither can do its work properly. Deficiency of wind is a complaint only too prevalent in instruments built in other localities besides the private drawing-room or music-room; but in Chamber Organs the disease is more likely to obtain, simply because there is, as a general rule, scant space wherein spacious lungs may be accommodated. It must be realised once for all, that it is in vain beautifully-voiced stops are planted on the wind-chests, that delicate mechanism is provided, and that swell-boxes are multiplied so as to secure satisfactory powers of expression, if the lungs are insufficient to pour throughout all the departments of the instrument an adequate supply of the breath which is the life thereof. There must be no misunderstanding about this matter—no compromise attempted: the bellows must be large enough, and so constructed as to meet the greatest demand that can possibly be made, and have wind to spare for as much again. Such being the case, it is obviously desirable to locate the supply bellows in some suitable apartment underneath or adjoining the organ, where there will be ample space for the bellows and whatever motor may be adopted for working the feeders. In the case of large church and concert-room instruments, the supply bellows are frequently located at a considerable distance from the organs; the wind being conveyed through long pipes, or trunks, to the reservoirs adjoing the wind-chests. Such an arrangement, however, is not to be recommended for a Chamber Organ; for it is important, if not imperative, that the wind furnished by the bellows be of the same temperature as the air of the room in which the organ stands. This fact must on no account be overlooked, for an instrument so delicately-voiced on so light a pressure is easily put out of tune by local currents of either cold or warm air, and especially by the wind passing through the metal pipes. Wherever the supply bellows are placed, arrangements must be made to convey wind from the organ-room to their feeders. This is best done by enclosing the bellows in a special chamber or box of wood, connected by an opening or trunk with the space immediately under or adjoining the organ. In the case of my own organ, the entire bellows—feeders, receiver, and pedal and manual reservoirs—are placed in a room directly under the organ, inclosed with tight woodwork, and supplied with air, from the music-room, through perforations in the floor. No better arrangement than this can be devised, allowing that the bellows-room is perfectly dry; but an adjoining room, on the same level as the organ, will answer equally well. It is, however, as a general rule, more difficult to secure such a room than one underneath the organ.

It is desirable to place the reservoir for the supply of the manual departments within the organ, as near as possible to the wind-chest, conveying the wind to it from the main receiver by a spacious wind-trunk, furnished, where it joins the reservoir, with a properly constructed valve or ventil. The reservoir for the wind of the pedal department may be at any reasonable distance, for there is not so great a risk of unsteadiness of wind in connection with the pedal pipes. It is highly desirable in all Chamber Organs to separate, as much as possible, the manual from the pedal wind, and this is most conveniently done by having separate reservoirs, supplied from a general supply bellows consisting of feeders and a receiver. The reservoirs must be weighted to give the required pressure of wind; while the general receiver must be weighted a little in excess, so as to keep both the reservoirs full at all times. Whatever the size and internal capacity of the receiver and reservoirs may be, it must be borne in mind that the continuous supply of wind depends entirely on *the capacity and satisfactory operation of the feeders.* There seems to be some uncertainty in relation to this fact, and our greatest writer on the organ has fallen into a strange blunder anent it. Let it be realised, once for all, that the feeders supply the wind; and that the receivers and reservoirs merely receive and store a very limited quantity for the purpose of imparting the required pressure or force to it—they are practically regulators of the wind, and it appears to me that they should be designated by the term, *regulators*, rather than by the name I have previously used, and by which they are commonly known. To speak of the different forms of feeders, and the construction of the most approved shapes of bellows, would be out of place in the present Notes; my readers must, therefore, be content with the above general hints regarding the lungs of the organ. Perhaps on some future occasion, should the Editor of this journal deem it expedient, I may be tempted to treat the Art of Organ Building in a thoroughly practical manner for the benefit of amateur builders and others interested in the subject.

Blowing Apparatus.

The present Notes would be obviously incomplete without some allusion being made to the appliances required for working the feeders, or what is commonly known as

"blowing the organ." For a Chamber Organ it is almost imperative that the operation of blowing be done without noise and out of sight, for nothing is more objectionable than the sight of an individual toiling away at the bellows handle—up and down eternally. Does not the handle seem to say:

"Men may come and men may go,
But I go on for ever"?

The necessity of doing this work noiselessly and out of sight is another strong argument for the location of the supply bellows in some neighbouring apartment. Blowing is both a monotonous and fatiguing operation, and when it has to be done by manual labour, let some contrivance be adopted to render it as easy as possible. The simple lever or handle should always be avoided when the feeders are detached from the organ proper. In the case of small instruments, which contain the supply bellows, the handle is generally the only means of blowing available, and it has then to be put up with as an unavoidable nuisance. When the supply bellows are situated in another room, the feeders, if they are of the ordinary form, should be three in number, and worked with a three-throw crank-shaft, supported on friction wheels, and having a flywheel and handle complete. By this arrangement the labour is reduced to a minimum, and great steadiness of blowing is secured. I commend this system to all who cannot afford, or cannot avail themselves of either a hydraulic or gas motor. When the bellows are encased, as above recommended, the ends only of the crank-shaft should appear outside—one end having the handle, and the other the flywheel. A wind indicator should, of course, be fixed close to the handle. The best form is that known as the "Eclipse Wind Indicator," invented and supplied by a firm in Boston, U.S.A. It is a most beautiful and ingenious little contrivance, mounted in a circular nickel-plated case, glazed. The indicating portion is formed of two discs of card—one white and the other black—so arranged, that in revolving the white one gradually covers or uncovers the black. When the bellows are empty the disc is entirely black, when it is full the disc is entirely white. Mr. Roosvelt usually places one of these indicators immediately over the manual claviers, in full view of the performer; so that he may at all times know the amount of wind in the receiver, and the manner in which the supply is being kept up. I believe I was the first to introduce the "Eclipse Wind Indicator" into this country; but it is but very little known in Europe at the present time.

I now come to the consideration of the motors or engines most suitable for blowing purposes, in connection with Chamber Organs. The only available and suitable powers are water and gas. The former, when it can be readily procured of sufficient pressure—say, from thiry to sixty pounds to the square inch—will always be preferred; but, as in my own case, when the supply is intermittent, gas becomes a valuable power. As very satisfactory gas engines of low powers are now made, and can be procured at moderate prices, no Chamber Organ of any pretensions need depend on the miserable hand blowing for its breath of life.

Water Motors.

For Chamber Organs, which require to be blown with the greatest possible steadiness, and without noise, the motor known as "Duncan's Patent Water Meter" is unquestionably the best yet introduced. As a proof of the absolutely perfect action of this motor, I may just mention the fact that a friend of mine placed one in his drawing-room, adjoining the organ, and merely covered with a glass case, without the slightest noise, vibration, or any other inconvenience arising from it. My own organ was, for a period of nine years, blown by a "Duncan," and it left nothing to be desired. This motor has two cylinders, with pistons and slide-valves, after the fashion of the steam-engine. The connecting rods to the blowing action extend directly from the piston rods. Sometimes only one piston-rod is connected with the feeders, but this is not to be recommended. When both are made use of, four feeders should be provided, worked, in pairs, by rocking beams connected with the piston rods in any convenient manner. By this arrangement the feeders are balanced and less power is expended. Full-drop feeders are to be preferred where practicable, so as to economise the consumption of water, and, accordingly, decrease the speed of the engine. For organs requiring a large supply of wind, double-action vertical feeders should be adopted, connected, in as direct a manner as possible, to the piston-rods. Of course, in the case of this, as in all other water motors used for organ blowing, the supply of water is regulated by a valve commanded by the rise and fall of the receiver of the bellows. Full particulars respecting this valuable motor may be obtained from Messrs. G. Forrester and Co., engineers, Vauxhall Foundry, Liverpool.

Of the single cylinder water motors, all of which are, more or less, jerky and noisy in their actions, I need say nothing here. I have done my duty in drawing attention to the most perfect motor in existence, to my knowledge, and so close my remarks.

Gas Engines.

It would be impossible, even if desirable, for me to consider the merits and demerits of the several gas engines in the market in a brief article like the present; but, as I am confining my remarks to matters relating to the Chamber Organ, the question of gas engines for blowing purposes narrows itself in a very satisfactory manner. For all organs which require a low power—say, from 2 to 4-man—I am firmly convinced the engine known as the "Bisschop" is the best. It is very simple in construction, and, accordingly, requires little attention to keep it in working order; it is vertical and compact in form, and, therefore, occupies a very small amount of floor space; it consumes very little gas; and it can be started with the greatest ease by anyone, after the first direction is given. It does not require to work at a high speed, and admits of control to a considerable extent without coming to a standstill; it requires no expensive fittings, water-tanks, or any special provision to be made for its reception; it is as noiseless in operation as one can ever expect a gas engine to be; and, lastly, it is the cheapest gas engine in the market. After a careful examination of the merits and demerits of all the engines known to me, I have decided in favour of the "Bisschop" for my own organ. Need I say more by way of recommendation? Particulars respecting the "Bisschop" gas engine may be obtained from Messrs. J. E. H. Andrews and Co., 80, Queen Victoria-street, London.

The chief difficulty in connection with the gas engine, in organ blowing, lies in the fact that it cannot be controlled like a water motor; that is, it cannot be made to work automatically—fast or slow, exactly in accordance with the demand on the wind.

Two methods may be followed with the "Bisschop." Fast and loose pulleys may be fitted on the crank-shaft of the bellows, and the belt moved from one to the other by a fork controlled by the rising and falling of the receiver; or a blowing-off arrangement may be adopted in combination with an appliance for reducing or increasing the speed of the engine within the imposed limits. The latter is the method I have adopted. When either of these methods are followed, it is advisable, if not imperative, to have reservoirs in addition to the receiver, so as to effectually prevent unsteadiness in the wind delivered to the pipes. The common objection to the blow-off system is the noise made by the escaping wind; but this can be entirely removed by covering the blow-off valves with a box or frame, over which is stretched a piece of thin flannel. The wind passes freely through this material without any hissing sound.

These remarks conclude my "Notes on the Chamber Organ." Hasty and imperfect as the Notes unquestionably are, I am gratified to learn that they have not been without interest to many readers of the English Mechanic.

DR. PAQUELIN'S AUTOMATIC BLOWPIPE.

An improved apparatus for generating and burning imflammable vapours has been recently patented in this country on behalf of Dr. Claude A. Paquelin, of 12, Place Vendôme, Paris. The invention relates to a sort of automatic blowpipe apparatus for the production of high temperatures; but it may be employed in its simple form for heating kettles, cauteries, soldering, branding, and goffering irons, and the like; and it may be combined with other parts so as to form a single apparatus or instrument of which it constitutes the heater. The heat developed by the apparatus may also be utilised for producing light by rendering a refractory material incandescent. In order that the invention may be more readily understood we have illustrated an example thereof in the accompanying drawings, and will proceed to describe it with reference thereto. Fig. 1 is a vertical section, and Fig. 2 a similar section taken on line 1—q of Fig. 1 of a lamp constructed according to this invention. The apparatus essentially comprises—1st, a closed vessel for the inflammable liquid traversed by a tube open at bottom, which is preferably central but may be at one side, the tube being surrounded by a wick or other porous substance which is immersed in the liquid contained in the vessel; 2nd, a jet nozzle within the tube in communication with the space for inflammable vapours generated in the vessel; 3rd, a chimney forming an extension of the tube wherein the gaseous mixture produced by the commingling of the jet of inflammable vapour with an induced current of air is burnt, and from which the burning mixture issues with force. The invention is based on the combination of these several parts, whatever may be the additions made for the purpose of adapting them to the various uses for which they are applicable. This combination permits of obtaining a large surface for heating the combustible liquid, of utilising the conductivity of the metal of which the apparatus is constructed, and of employing for the purpose of vapourising the liquid only the heat concentrated in the chimney without exposing the vessel to the direct heat of a fire. a is the closed vessel, which may be made of cylindrical or other form, and b the central tube passing up through it and surrounded by porous meaterial c. The jet nozzle d is placed within the tube b near the upper end and communicates by a duct e with a chamber f at the upper end of the vessel a. It is filled with a bunch of metal wires to filter the vapours and prevent the jet becoming choked. The chamber f is separated from the vessel a by a diaphragm having perforations g to permit the inflammable vapours to pass the nozzle d. This diaphragm may, however, be omitted, the vapours being contained between the top of the vessel a and the upper end of the wick or porous body c. h is the chimney into which is discharged the gaseous mixture formed by the vapour from nozzle d and the air drawn in at the open bottom end of tube b or at any other inlet which may be provided for it. The chimney may be a fixture, but it is preferable to make it separately and fit it upon the cross-tube e carrying the jet nozzle. The vessel a is provided with a filling orifice closed by a screw plug k, and also with a circular channel or gutter l at bottom, into which dips a pipe m, passing down through the vessel a and terminating at top in a funnel mouth n. The apparatus is supported upon a perforated bottom ring o, and the

FIG. 1.

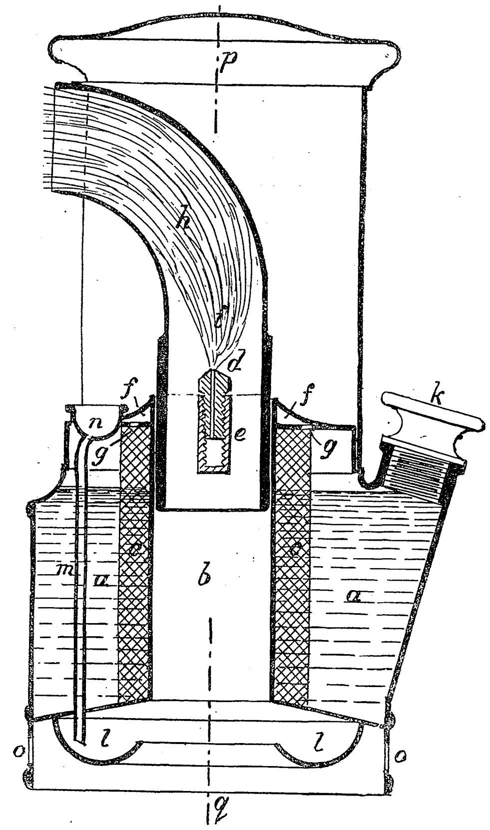

FIG. 2.

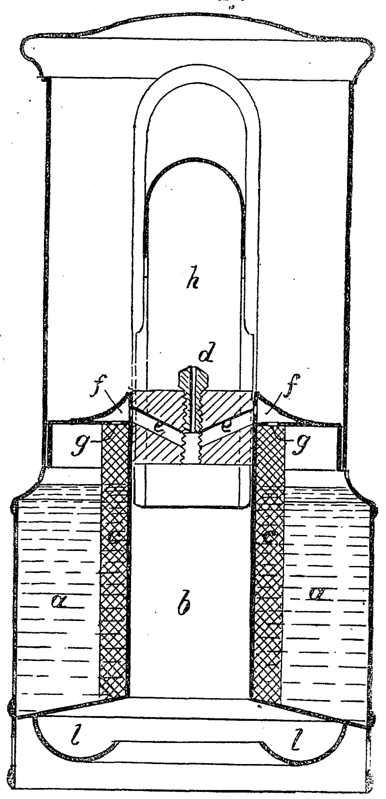
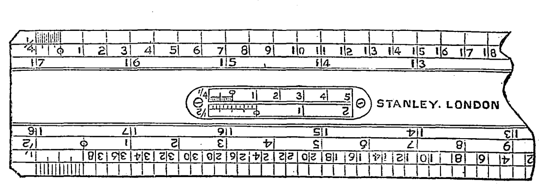


chimney is protected by a cap *p*. To use the apparatus, the vessel *a* being filled with inflammable liquid and the plug *k* screwed down tight, a small quantity of petroleum spirit or other inflammable liquid employed in the apparatus is poured into the circular gutter *l* through *n* and *m*, and is ignited beneath the vessel *a* to heat the vessel and start the generation of inflammable vapours, which, rising into space *f*, issue under pressure at nozzle *d*. By the inductive action of the jet, air is drawn through the tube *b*, the mixture thus formed constituting a forced jet, which ignites of itself in the chimney if a sufficient quantity of priming liquid has been used. The priming liquid in the gutter *l* being now consumed, the apparatus will continue to work automatically until the supply of liquid in vessel *a* is exhausted, this automatic action being due to the heat of the flame *i* conducted by the metal, of which the chimney *h*, tube *b*, and vessel *a* are made, to the liquid contained in the vessel and the porous substance enveloping the tube. The vapour is generated as fast as it is consumed at the nozzle *d*, so that the apparatus continues to be supplied. The apparatus when once started acts with great regularity, and there is no risk of explosion, inasmuch as in the event of the jet nozzle becoming obstructed the flame would be thereby extinguished. If desired, the apparatus may be provided with one or more regulators; for example, there might be applied at the base of the chimney *b* a fixed and a movable perforated part by adjusting the one on the other, of which the size of the apertures may be regulated so that the heat will be concentrated upon the chimney and the action of the apparatus be increased, and conversely if the perforations be made to coincide. Another similar regulator may be placed at the base of the apparatus to limit the influx of air to the tube *b*, which may consist of a perforated band movable around the bottom ring *o* so as to close the orifices more or less. Or a valve, cock, or other regulator, may be employed for controlling the draught. The several parts of the apparatus may be varied; as, for example, the container may be made of any form and the tube *b* be either open or closed at bottom, as before explained, the mixing of the air with the inflammable vapour being effected in the latter case at the base of chimney *h* only. The air may also be introduced partly through the tube *b* and partly through the chimey *h*. The nozzle *d* may also be placed at any suitable height of the central tube, but preferably at its upper end, in order that the vessel *a* may not be exposed to the direct heat of the flame but only to the heat transmitted by the metal. The gutter *l* may also be replaced by one of a similar kind, placed at the top of the container *a*, in which case one or more openings would be required at the base of the chimey for igniting; or the gutter may be entirely dispensed with and the apparatus be heated by placing it on a separate stand. In order to supply the gutter *l* in the apparatus shown with the exact quantity of petroleum required, a drop bottle or pipette, graduated if desired, may be provided. All the accessory parts of the apparatus would vary according to the purpose for which the apparatus is to be used, and the essential parts consisting in the combination of the container, central tube, nozzle, and chimney, may be applied to all kinds of apparatus such as soldering, branding, or goffering irons, &c., and would therefore vary in form and dimensions.

STANLEY'S PATENT ARCHITECT'S AND ENGINEER'S SCALE.

THE inch divisions at the end of ordinary feet and inches scale soon become faint by constant use, this part of the scale being always used. To avoid this, in the improved



scale a short piece of metal work is inserted at each end of the scale, upon which is divided a repetition of the ends of the scales. This metal scale is intended for taking off short dimensions, as the sections of timbers, thickness of brickwork, &c., with the dividers or with pencil bow. The metal is soft enough not to injure the steel points of the compasses, and yet hard enough to bear ten times the wear of the ordinary scale. Anyone using this scale may always keep sharp, clear divisions on the edge, and work more exactly than with an ordinary scale, even where only slightly worn.

SIMPLE EXERCISES IN TECHNICAL ANALYSIS.—XVI.

By an Analytical Chemist.

Oils (*continued*).

(226.) THE following table gives the results of the examination of a very large number of samples of oils in common use. Of the three columns of specific gravities, the *first* contains the figures given by the best authorities for pure oils; the *second* those obtained for the majority of samples within the writer's experience; the *third* contains the gravities representing a considerable proportion of the total number of samples examined. The second and third columns may be taken as fairly representing the gravities of oils prepared in the ordinary way, and sold in the market during recent years; but the figures in the third column must not be regarded as the extreme limits for good samples.

With the exception of sperm oil, the figures in the first and second columns practically agree, or only differ to an extent corresponding to the difference between a sample prepared in or for the laboratory, and a commercial sample. It would appear that sperm oil of a gravity of ·875 is rarely to be met with in commerce.

Linseed Oil.

(228.) The tests given in these papers are chiefly with a view of determining the suitability of an oil for the particular purpose for which it is intended to be used, and are therefore not solely confined to a determination of the purity or impurity of the sample.

(229.) Linseed oil is used for paints, varnishes, printing inks, and in the manufacture of floorcloth. Its suitability for the latter purpose is determined on the large scale in the following practical manner:—Two gallons of the oil, with one per cent. of a mixture of equal parts of ground litharge and red lead, are boiled in an iron pot for from two to four hours, and at a temperature not exceeding 260° C. The process is quickened by blowing in air from an ordinary bellows. Samples are taken out from time to time, and cooled on an iron plate. If the sample becomes stringy when cool, the pot is removed from the fire, and the contents

stirred until cold. A suitable oil should be solid when cold; an unsuitable one would be semi-liquid or sticky.

(230.) The suitability of linseed oil for painting is determined by the following tests, which also apply génerally to oil for floorcloth, or for any other purpose :—

(*a*) Spec. grav.
(*b*) Inorganic matter, freedom from.
(*c*) Drying properties ; elaïdin test.
(*d*) Freedom from excessive acidity.
(*e*) Sulphuric acid test.
(*f*) Temperature at which fat deposits.

(*a*) *Specific Gravity.*—This is usually given in textbooks as ·930 —·935. There is so much difference in the method for extracting the oil that the limit is necessarily wide. My own figures show that ·931—·933 are the most common gravities, thus :—

s.g. ·930	7·7 per cent.	of the total number of samples examined.
·931	16·0 „ „	
·932	55·0 „ „	
·933	14·7 „ „	
·934	5·3 „ „	
·935	1·3 „ „	

Oils of the lower densities are expressed without artificial heat, and are of better quality ; but they do not keep so well as those of higher densities.

(*b*) *Inorganic Matter.*— Gently ignite two grammes in a porcelain basin until all the black carbonaceous matter has disappeared. The residue should not weigh more than ·05 per cent.

(*c*) *Drying Properties.*—A simple way of applying this test is by placing one drop on one sheet of glass and two drops on another ; spreading the oil on each glass as evenly and thinly as possible, by working the finger in a circular direction, beginning with the drop as the centre, and gradually extending the circles until the oil will reach no farther. Allow the glass sheets to stand in a place protected from dust, and at the ordinary temperature. A good oil will be "tacky" after 24 hours, and should be dry in from 40 to 48 hours. The kind of surface formed is also a matter of importance. A tough elastic surface is characteristic of good oils, and *vice versâ*.

The sheets of glass must be quite clean and free from grease or dirt before using ; the same sheets can be used again and again. A few drops of strong alcohol, followed by gentle rubbing, readily remove the oil from the glass.

As linseed oil is almost invariably used on account of its drying properties excelling those of any other oil, it is hardly necessary to remark that this test is a most important one.

The elaïdin test described in Art. 220 is also very useful in detecting adulteration in the form of a non-drying oil. Linseed being a rapidly drying oil, no solidification should be produced by this test, which it is always desirable to make at the same time and under exactly the same conditions on a sample of known purity.

(*d*) *Acidity.*—10cc. of the oil and 10cc. of neutral alcohol (60 o.p.) are shaken thoroughly, and then allowed to rest. The alcohol rises to the top, and 5cc. of the clear supernatant spirit are taken and titrated with decinormal soda solution, using litmus or phenol phthalein as an indicator. The number of cc's. of decinormal soda solution required to neutralise the 5cc. taken, when multiplied by 20 and ·006, gives the percentage of acid calculated as acetic. In good fresh samples the acid dissolved by the alcohol does not exceed 0·15 per cent. of acetic.

(*e*) *Sulphuric Acid Test.*—This is a colour test. Twenty drops of oil are placed on a small perfectly clean and white basin, or on a sheet of glass with white paper underneath, and in the centre of this one drop of the strongest sulphuric acid (s.g. 1·84) is carefully let fall from the end of a glass rod previously lowered until it nearly touches the oil. The acid acts powerfully on the oil, and in a few seconds a brown compact clot forms, which gradually deepens in tint until it becomes a dark chocolate. A loose clot, or the production of a different tint, would indicate the presence of other oils. But it is only an indication, for linseed oils are occasionally met with which do not exactly correspond to this test. Description fails to convey a clear idea of the colours produced in these colour tests. The best plan is to obtain a sample of first-class quality, and treat the two samples side by side in exactly the same way. This remark applies generally to the colour tests.

(*f*) *Temperature at which Fat deposits.*—This is a good test for linseed oil, as its solidifying point is as low as about − 20° C. Fat begins to deposit at about − 11° C.

(231.) The foregoing are the tests usually applied ; but others must be made if the results now obtained are not satisfactory.

The solubility in alcohol is a useful test. Linseed oil is soluble in 5 parts of boiling and 40 parts of cold alcohol.

The rise of temperature, as described in Art. 218, is a very important test, as the presence of other oils lessens the effect. The rise usually obtained varies from 100° to 115° C. But this test cannot be so satisfactorily performed on linseed as on other oils, owing to the rapidity with which the temperature rises, and the almost certain loss from the oil frothing over the glass in which the experiment is made.

It has been suggested to add a certain quantity of mineral oil—on which the acid has only a slight action—to the linseed oil before making the experiment ; but this plan is open to two objections—it necessitates two tests where one was previously sufficient, and it removes linseed oil from the comparative table of increases of temperature. These increases of temperature are of no value except for comparison one with another, and, therefore, they must all be obtained under like conditions. Whatever method is adopted for linseed oil should be extended to all the others.

(232.) Linseed oil is still very largely adulterated. But some of the oils formerly used as adulterants are now as valuable as itself. In searching for adulterants the analyst must make himself familiar with the market prices, and be guided accordingly.

The most common adulterants are rosin oil and cottonseed oil ; but there is practically no limit to the sophisticator's art. It is usually of much less importance to the practical man to give a name to the adulterant than to find out that the oil is not genuine and not suited to his purpose.

Rosin oil imparts a very unpleasant taste to linseed oil. It also raises the s.g., its own being about ·96 to ·98.

Although refined cotton-seed oil is now more expensive than linseed itself, inferior qualities are still occasionally used as adulterants of linseed oil. Cotton-seed oil affects the foregoing tests in the following way :—

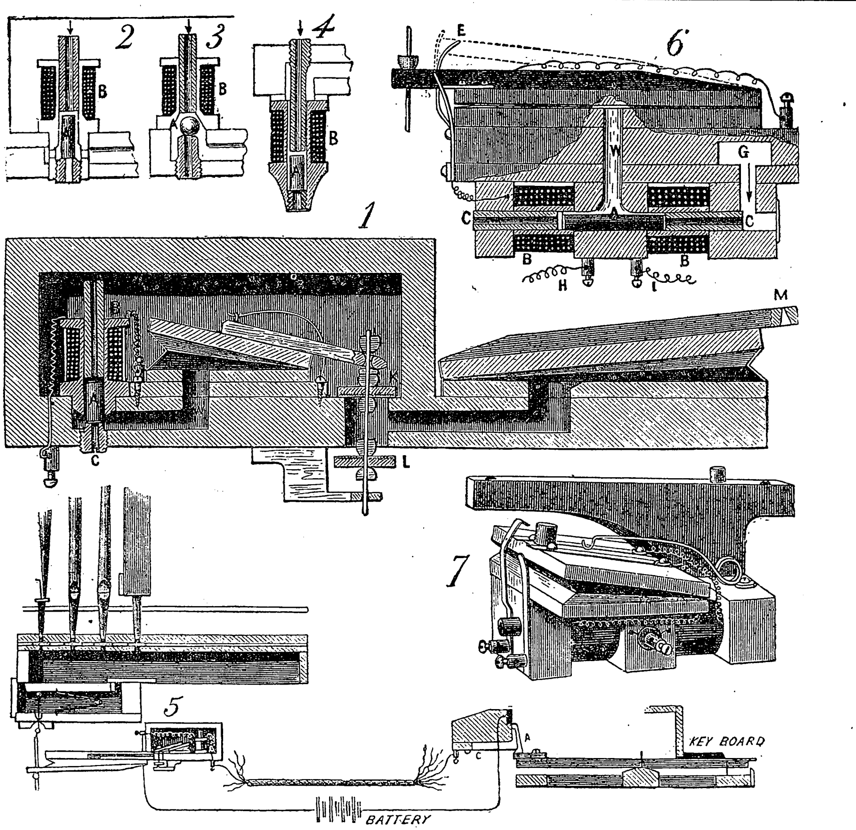
(*a*) It reduces the s.g.
(*b*) The drying properties are impaired.
(*c*) Fat deposits at or about 0° C.
(*d*) Sulphuric acid produces a violet colour.
(*e*) The increase of temperature with sulphuric acid is less.

Some linseed oils are very deficient in drying qualities, and are wholly unsuited for paints. "Baltic" oil is the best variety.

(*To be continued.*)

ELECTRO-PNEUMATIC ORGAN ACTION.

IN Vol. XXX. p. 525, we gave an illustration of the arrangement of the key-box and a specification of the great organ built by Mr. H. L. Roosevelt for the Cathedral in Garden City, Long Island, U.S.A. We give now an illustrated description of the electro-pneumatic action, invented by Mr. George Walcker, of New York, which has been tried and found to work excellently in the great organ of the Cathedral of the Incarnation. We need not repeat the specification. It will suffice to say that there are four manuals of five octaves each, and pedals, with 115 speaking stops, and 7,252 pipes (when completed). This remarkable organ is distributed over the cathedral in four distinct and widely separated portions ; but the key-box is in the choir, and all parts of the organ are under the complete control of the performer. The largest portion is in an octagonal chamber in the angle formed by the transept and chancel walls, and includes (in separate tiers) the great, the swell, and the choir organ, the reeds and mixtures of the pedal being included in the same swell-box as those of the great organ. Part of the pedal organ projects into the choir and part into the chancel, while another portion is placed, with parts of the great, swell, and the whole of the solo organ in the tower. Another portion of the organ is placed in the chapel beneath the cathedral, and comprises part of the choir organ and two of the pedal stops ; and the remaining portion, consisting of the echo organ and one pedal stop, is located between the ceiling and the roof. Separate claviers are provided where it is required at times to use one of the divisions, and also for tuning purposes ; but the object of the division was to obtain the most varied antiphonal effects. For instance, in the processional hymn with which the service commences, the choir form in the chapel, and their voices are accompanied by the chapel organ ; but as they come up into the body of the church, the tower organ takes up the accompaniment, and then as they reach the chancel, the division of the organ there located is brought into play. It will be easily understood that with the organ in the roof marvellous effects can be produced, especially as each division is provided with a swell-box. It is time, however, to describe the electric action as applied in connection with the well-known pneumatic devices, and a reference to Fig. 1 will give an idea of the arrangement adopted. The pneumatic movement is controlled by the electric attachment. Within a windchest a hollow cored electro-magnet, indicated by B, is mounted in a vertical position. A cylindrical armature, A, plays up and down below it. The armature fits loosely in a cylindrical chamber directly below the magnet. Its top and bottom are covered with discs of leather. Below the armature a nozzle C communicates with the open air. The windchest is in constant communication with the organ bellows, so that the air within it is maintained at a pressure above that of the atmosphere. Within it is a bellows that is held open normally by a spring. It will be seen that when the armature has fallen the bellows is filled with air from the windchest. The pressure is carried down through the hollow-core and space surrounding the armature and through the passage W ; the bellows, under the circumstances, being in equilibrium, remains distended, closes the valve K, and keeps the valve L open. This leaves the outer bellows free to remain open or shut, the tracker attached to the arm at M, acted on by the pipe-valve, keeping it shut. When it is desired to sound the pipe a current of electricity is passed through the wire. This draws up the armature and closes the opening in the magnetic core, and at the same time opens the nozzle C. The bellows in the windchest, having its interior put in communication with the outer air, at once closes under the effect of the air pressure within the box, and opens the valve K, which action closes the valve L, so that the outer bellows is forced open by the pressure from the windchest. The tracker is caused thereby to open the pipe valve, and the pipe begins to speak. In Figs. 2, 3, and 4 different modifications of the magnets and armatures are shown. All this is done so quickly that a sensitive pipe can be made to speak six hundred times a minute. These are the pipe movements, and one such magnet and attachments are supplied for each key in the manual and for each pedal key. For the draw stops a somewhat different apparatus is provided. Elevations of the draw stop mechanism are given. Two magnets, BB, are arranged horizontally, and supplied with a horizontal cylindrical armature, which is permanently magnetised. It is attracted to one or the other of the magnets, according to the one the current is caused to pass through. Air-pressure from the organ bellows comes through the passage G. When the armature A is attracted towards the left, as a current passes through the left-hand magnet, this air pressure raises the bellows and opens the stop. As the bellows rises, the spring F breaks contact with the piece D. This cuts off the left-hand magnet from the line ; but the polarisation or magnetisation of the armature causes it to retain its place. Hence the bellows stays open. But in rising by means of the spring E, and another contact piece corresponding to it, it throws the right-hand magnet into its own circuit. Then, when another pulse of electricity is sent by the opposite movement of the stop handle, it passes through the other magnet, and draws the armature to the right. The bellows under the influence of the spring shown in Fig. 7 collapses, closes the draw stop, and at the same time cuts off the current of electricity.



A separate wire is provided for each magnet going from the draw-stop handle; but a single return wire acts for both. The horizontal position of the magnets in conjunction with the polarised armature are the distinguishing features of this mechanism. The bellows acts by a tracker directly on the stop valve. One of these movements is supplied for each stop, and thus the whole range is controlled by electricity. An idea of the connection between manual and soundboard will be found in the section shown in Fig. 5. To the right is a key in its normal position. When depressed by the finger, it makes an electrical connection between the oscillating piece A and the contact piece B. All the magnets connect at one terminal with a single wire, which runs from them to the contact piece B, and includes in its course the battery. Each of the other terminals of the magnets has its own wire, which runs to the manual, each wire being connected by the binding screw and spring C to its own key. Hence when a key is depressed it actuates the magnet connected with it, and makes the corresponding pipe give its note. On the left of Fig. 5 will be seen the valve and action illustrated by Fig. 1, attached to the trackers leading to the pipe valves; but in this instance the "outer bellows" is below instead of above the supporting board, for reasons which will be obvious. Although these devices may appear complicated, and likely to get out of order frequently, we believe that the electricity has never failed to do its appointed work, while the great wind-valves, some of which have an area of 14in., are opened and closed with certainty and rapidity. We should perhaps mention that the current is supplied by a machine—not by a battery—while steam-engines are employed to work the bellows.

IS JUPITER SELF-LUMINOUS? *

In the concluding part of my paper on the occultation of Jupiter in April last, I referred to the question of Jupiter's intrinsic brilliancy, and expressed the hope that the question would be scientifically investigated. In order to clear the way, I will first state the case. Jupiter is, roughly speaking, about five times the earth's distance from the sun. It is impossible, therefore, that he can receive from that luminary more than one twenty-fifth part of the intensity of illumination which reaches the earth; that is, in inverse proportion to the squares of the distances. Now, from the time of my first telescopic acquaintance with Jupiter, I was struck with the impression that his brightness far exceeds what, by the above rule, it ought to be. The question naturally arises, how is this want of accordance with the laws of radiation to be accounted for, presuming it to exist? Some modern astronomical works just refer to this question, but as a rule they pass it over lightly.

The recent conjunction of Jupiter and Mars (28 June) was looked forward to with interest by me, as furnishing a favourable opportunity for photometric experiments with reference to the relative intrinsic brightness of these two planets; and I commenced my preparations several days beforehand. At the risk of being somewhat tedious, I think it will be well to describe in detail the means I adopted, in order that the results may be judged of at just what they are worth, and no more. I constructed a diaphragm (or shutter) for the telescope (8½in. reflector), consisting of two half-discs, pivoted at their circular centres, and graduated on their rims in degrees. This enabled me to shut off any proportional part of the aperture of the telescope from one half to the whole.

In order to equalise the conditions, so far as to have equal visual areas in comparison, I covered the field-bar of the eyepieces used with tinfoil (blackened), leaving open (for finding the object) a segment only, about one-third of the field. In the centre of the tinfoil I pierced a small hole with the point of a fine needle.

In observing, I used a Barlow lens in conjunction with the eyepieces, so as to enlarge the focal image. I at first employed the sun-prism (the image being viewed by reflection from the first surface of clear glass), thereby getting rid of the greater part of the illumination. This was still further reduced by a 3in. stop to the telescope. For comparison, a lamp was inclosed in a cupboard having an aperture covered with paper. The image of Mars being brought to the needle hole, the shutter was gradually closed until the brightness of the image equalled that of the lamp-light. The different readings gave an average of 90°. Dealing with Jupiter in the same way, the average was 29°.

I next varied the experiment by removing the sun-prism, and substituting a dark wedge (a makeshift affair for the occasion, composed of two slips of glass, in contact at one end, the other ends being slightly separated, the intervening space being filled with Canada balsam mixed with lamp-black). A suitable darkening with this being obtained, it was retained in position, and the shutter used for equalising the illumination. In this experiment each image was reduced to the minimum of visibility. The averages of the readings were 102° for Jupiter and 146° for Mars.

Between these two sets of measures there is considerable discordance; but they both agree in making Jupiter's surface much the brighter of the two—in the first set as 90 to 29, or nearly three times; and in the second as 146 to 102, or nearly 1½. Taking the mean, we have as 118 to 65, or nearly double. Their relative distances from the sun at that date were as 15,747 to 54,561. The proportion of the squares of these numbers is almost exactly as 1 to 12; Jupiter, then, instead of being $\frac{1}{12}$ the brightness of Mars, is by the above measure nearly double, or about 22 times as bright as he ought to be by the laws of radiation. The near conjunction of Jupiter and the moon on 7th July furnished opportunity for comparison between these bodies. On this occasion the readings averaged 180° for Jupiter and 80° for the moon.

I had not yet done with the question. In my experiments I had, by various means, stopped back all but the smallest fraction of the light received. The inquiry arose, did this small amount represent equal percentages from both bodies? I settled this question at home thus:—A small hole $\frac{1}{10}$in. in diameter was pierced in a bit of sheet metal and covered with tracing paper. This, with a flame behind it, made a capital artificial planet. I improvised a small telescope out of a short focus photo combination, using the same eyepieces as before and the dark wedge. To this arrangement I adapted a graduated shutter as before described. The light—a small gas flame—was inclosed in a magic-lantern, the lenses being removed; measures were then taken of the intensity of light as received upon the spot of tracing paper, the flame being at 1ft., 2ft., 3ft., 4ft., and 5ft. distant respectively. The average of a series of readings for these several distances in order was 180°, 110°, 61°, 31°, and 6°. Theoretically they should have been 175°, 112°, 63°, 28°, and 7°. This was, I think, sufficiently near to show the general correctness of the principle.

To sum up, then. As compared with Mars, I make Jupiter's surface brightness to be 22 times as great as it ought to be, and as compared with the moon 12·7 times. These comparisons, of course, go on the assumption that the surfaces to be compared are equally reflective—that is, of equal whiteness. That they are really *not* so may be considered as certain. But even supposing Jupiter's surface to be of the *whiteness of snow*, we have at the poles of Mars planetary snow with which to compare it, and illuminated with twelve times the intensity of Jupiter's sunshine; yet even this comparison I judge to be in favour of Jupiter. As compared with the moon, the vaporous envelope of Jupiter (whatever its nature) is probably more reflective than the bare and broken lunar surface. There *must*, however, remain a vast amount of illumination to be accounted for in some other way.

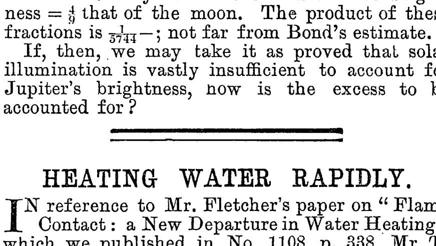
I must say that the result of my measures appears incredible even to myself. I therefore look for some corroboration. According to Mr. G. P. Bond's estimate, the light we receive from Jupiter amounts (at a mean) to $\frac{1}{6430}$ of that of full moonlight. Jupiter's visual disc (mean) is $\frac{1}{2553}$ of the full moon. My estimate of his surface brightness = $\frac{4}{9}$ that of the moon. The product of these fractions is $\frac{1}{5744}$—; not far from Bond's estimate.

If, then, we may take it as proved that solar illumination is vastly insufficient to account for Jupiter's brightness, how is the excess to be accounted for?

* Extracted from a paper read by Mr. A. B. Biggs before the Royal Society of Tasmania.

HEATING WATER RAPIDLY.

In reference to Mr. Fletcher's paper on "Flame Contact: a New Departure in Water Heating," which we published in No. 1108, p. 338, Mr. T. Pray, jun., of Hartford, Connecticut, writes:—Mr. Fletcher has done himself credit in his "heating" inventions; but in the idea advanced in the item referred to, he has been fully anticipated by at least thirteen years, if he puts forth the idea as an invention. With this exception: he advises copper studs, while iron was my own medium. With this please find sketch of an arrangement



which was used in 1873 upon two steam boilers, and in 1876 upon a greenhouse boiler of 30in. diameter, 54in. long, which displaced two large and one small cast-iron greenhouse boilers, and heated 9,000ft. of glass far better than the three did the previous winter, and with far less coal.

The first experiment was made by rivets 1¼in. diameter next the shell, 1in. diameter at small end, and set the whole length of both fire sheets and for nearly half the circumference of the boiler, 3½in. from centre to centre in alternate rows and spacing Fig. 1 shows first experiment, Fig. 2 the second. All sorts of trouble was promised by boiler-makers, but no trouble or expense of any kind ever came from the arrangement or boilers. The record of evaporation was high, no leakage occurred, and not

a cent was called for in repairs; and so far as my own experience goes, no other application has been made of the idea in this country (U. S. A.)

ON THE COLLECTION AND METHOD OF STUDYING FORAMINIFERA.*

By J. M. Flint, Surg. U. S. N.

I HAVE taken occasion to bring before the society, for the inspection of those who may be interested either biologically, geologically, or æsthetically, some specimens of the foraminifera collected by the Fish Commission steamer *Albatross* during the last 18 months, and selected, prepared, and mounted on board during the cruise.

The specimens before you are the beginning of what is intended to be a type series of this interesting group of animals. It already includes representatives of all the orders except Gromidæ, which are principally freshwater forms, and about half the genera mentioned by Brady in his *Challenger* Report, and numbers 125 species. The collections were all made on our Atlantic coast, and with the exception of a very few—not more than half a dozen species—were taken off the coast between Cape Hatteras and Martha's Vineyard.

Great quantities of this material are obtained by the *Albatross*, and its separation and preservation have been greatly facilitated by the devices of Mr. Benedict, the resident naturalist of the ship. The material is brought up from the bottom by means of what is known in the vernacular as the "mud-bag," a canvas bag about 2½ft. long by 18in. wide, the mouth held open by an iron frame. This bag is attached to the free end of the net of the beam-trawl, and it rarely fails to scoop its full of mud as it is dragged over the bottom. Being brought to the surface the mud is dumped into the table-sieve, the hose turned upon it, breaking up the lumps and carrying all but the coarsest particles through the sieve, where it falls into a tub below. This tub has several holes at different heights at the side; these holes are stopped with spouts, and over the spouts are fastened strainers made of fine linen "scrim." The heavier foraminifera fall at once to the bottom of the tub, the impalpable mud and the lighter foraminifera flow out through the openings of the tub, where the latter are stopped by the strainers. The material thus obtained is a comparatively clean mixture of sand and foraminifera, the proportions of each depending upon the nature of the bottom. Before being ready for examination this material requires a further thorough washing by decantation. It must then be washed with fresh water to prevent the formation of crystals of salt, and thoroughly dried.

The individual shells are picked out under a dissecting microscope by means of a fine camel's-hair pencil, moistened between the lips.

I may be excused for calling your attention to the method of mounting, since it is the only thing connected with the subject for which I can claim any originality. It was soon found that for the purpose of thorough study for identification of specimens the usual method of permanent mounting was extremely unsatisfactory. For the examination of objects of this character under the microscope nothing can equal what is known as Beck's discs and holder. By means of this accessory an object may readily be rotated in the field of view of the microscope so that all sides of it may be examined except that actually adherent to the discs. These discs are made of brass, with a short stem for insertion in the arm of the holder. By means of a fine chain concealed within the arm and passing around the axle of the milled head, rotation around a perpendicular axis is obtained; and the whole arm being permitted to revolve in its support, rotation around a horizontal axis is also secured. By a combination of these movements the object may be placed in any desired position without losing it from the field of view. The great advantages attending the use of this appliance led to the mounting of the whole series upon discs, any one of which may be placed in the holder and thoroughly examined. The specimen being secured to the disc, the latter is inserted into a wooden slide of the usual dimensions, and may be arranged in a cabinet in the ordinary way. For protection of these frail shells from dust and accident a cover is necessary, and it must be removable in order to get access to the specimen when it is desired to transfer it. This cover is supplied by curtain-rings, cemented one upon the other, and capped with thin glass, and it is secured by small tacks driven just far enough apart and just deep enough, so that the heads will catch in the groove between the rings. The cover is thus easily removed and replaced. For exhibition purposes, and for permanent preservation and reference as well, cardboard discs have been prepared. The specimens are planted in succession, as near the circumference as possible, and the covers fitted as on the single slides. This cardboard disc is designed to rotate on a pivot supported by the upper stage plate of the microscope, and by means of this rotation each object in the series may be brought, in succession, into the field. The dropping of a light spring into a notch on the edge of the disc indicates to the observer when the object is in proper position. The mechanical stage movements give control of the object as if it were on an ordinary slide. In the collection before you, one disc has been devoted to each family. From each of these have been selected the specimens on the disc under the microscope, to which your attention is specially directed. Whenever necessary to identification or to elucidation of structure, sections of the shells have been made, and the sections mounted on the same slide with the entire specimens. Some few very thin or delicate specimens have been mounted in balsam, as it brings out more distinctly the peculiarities of structure. These are placed on the discs for examination by reflected light; they may be removed and placed on a glass slip and viewed by transmitted light, if desired.

It may not be altogether amiss, even in a society of biologists, to recall a few facts regarding this group of animals, apologising to those who have made the subject a study for the trite remarks.

The Foraminifera comprise a group of animals belonging to the sub-kingdom Protozoa, class Rhizopoda. They stand nearly at the foot of the list in the classification of animal organisms by reason of the extreme simplicity of their structure, which consists of a minute bit of protoplasmic substance without differentiation of endosarc and ectosarc, without contractile vesicles, and until recently believed to be without even a nucleus. Like the other rhizopods they possess the power of thrusting out portions of the body substance or pseudopodia, which, when retracted, lose themselves again in the body mass. The character of these pseudopodia has led Dr. Carpenter to divide the Rhizopoda into three classes:—1. Lobosa, of which *Amœba* is the type, the pseudopodia of which are blunt or irregularly club-shaped, and show no disposition to unite with one another when they come into contact; 2, Reticulosa, to which class belong the Foraminifera, whose pseudopodia, projected in fine threads, unite whenever they come into contact, forming a network; and, 3, Radiolaria, of which *Actinophrys* is the type. The pseudopodia in this instance are projected radially, and do not unite.

But little is known of the life history of these minute and simple animals. Their ordinary mode of multiplication is undoubtedly by subdivision or fission. But there seems to be some definite limit to the possibilities of that process, and it is probable that some form of conjugation and encysting process will ultimately be discovered. Their mode of nourishment is supposed to be by the absorption of the organic matter in solution in the sea-water, since the pores of the shell are, in most instances, too small (the largest being about $\frac{1}{5000}$in. in diameter) to allow the introduction of any solid particles of food likely to be within their reach. All species of this group surround themselves with some form of shell or test, and the fact to which they owe their chief importance is their ability to separate carbonate of lime from its solution in the sea-water.

Of their distribution it may be said that, with the exception of polar seas, it is as wide as that of the waters of the ocean. The sounding-cup never fails to bring them from the bottom, and in some parts of the Atlantic the mud dredged consists of as much as 85 per cent. of foraminifera. Wherever the ocean has rolled in past geological ages since any living thing has existed, they have been. The chalk beds all over the world are composed almost exclusively of their remains. These chalk beds in this country cover thousands of square miles, and in some places are 9,000ft. in thickness. They are probably not less extensive in other parts of the globe.

The nummulitic limestones extending in a vast bed on both sides of the Mediterranean, through Northern India and Central Asia, are principally shells of Foraminifera, and get their name from a genus of large size, very numerous and conspicuous throughout the stratum. The Pyramids of Egypt are built of this stone, and rest upon rock of the same structure, in which the fossil foraminifera are easily visible to the naked eye. It is probable that the subcarboniferous limestones have the same origin. In short, the weight of evidence is that the foraminifera have had more to do in forming geological strata than all other animals taken collectively. Moreover, if the conclusions of Drs. Carpenter and Dawson in regard to the *Eozoon Canadense* are accepted, the foraminifera are the oldest in geological time of known fossils. So these minute shells, the product of the simplest of animal organisms, are not so insignificant in the economy of nature as they might at first appear.

Aside from their geological importance and biological interest, they attract attention by the beauty and infinite variety of their forms, and they illustrate better than any other series of animals the endless varieties that may be produced by the slight but persistent modifications of the mode of growth.

In all attempts at classification of such objects as these, external form must necessarily be the governing principle. There are, however, a few prominent distinctions based on physiological differences which should be considered. For instance, a large group of these animals form their tests of grains of sand, spicules of sponge, or the shells of other foraminifera. They repeat, in a rude way, nearly all the forms taken by the more delicate calcareous shells; but the physiological distinction is of more importance than the external resemblance, and properly causes the testaceous foraminifera to be classified apart from the calcareous foraminifera. Another broad distinction is based upon the arrangements for the protusion of the pseudopodia. In a portion of the group the shell is "imperforate," by which is meant that there is only one mouth-opening through which the pseudopodia can be thrust out. In the others the shell is porous, or "perforate," studded all over with minute openings, the largest not more than $\frac{1}{5000}$in. in diameter, through which portions of the body substance are extended for the absorption of nutriment. These latter generally have a conspicuous mouth-opening also, but this opening is believed to serve simply as an exit for the sarcodic substance in the process of growth. These then constitute the principal divisions based upon physiological differences which can be sustained—viz., into arenaceous and calcareous, and into perforate and imperforate. Other distinctions are based upon external form alone, and it is interesting to consider by what simple modifications the most astonishing results are brought about.

* A paper read before the Biological Society of Washington.

USEFUL AND SCIENTIFIC NOTES.

The Food of Paris.—The annual consumption in Paris of various kinds of food which can be closely controlled by the registers of the *octroi* was during last year 146,825 tons—an increase of 446 tons over the previous year. Of pork 148 tons had been consumed less, while the consumption of horseflesh, with a total of 3,830 tons, had augmented 337 tons, as compared with 1884; the average price of this last-named commodity is sixty centimes a kilo, while the meat of asses and mules command about seventy centimes. Of poultry and game the aggregate consumption was 25,044 tons—a slight diminution as compared with the year before. The quantity of fish, &c., amounted to 25,631 tons—a slight augmentation, more particularly in oysters. The consumption of butter and eggs has fallen off by nearly 160 tons, which decrease, so far as butter is concerned, may readily be accounted for by the greater use of margarine.

A Monster Electric Clock.—The Standard Electric Time Company, of New York, has, according to the *Electrical World*, been engaged for some time past in preparing the mechanism, &c., for the largest clock in the world, one having a face 25ft. in diameter. This clock is to be put against the wall of a building at the corner of Twenty-third-street and Fifth-avenue, resting on a lower building at the junction of the thoroughfares. The works are composed of sixteen pairs of electro-magnets placed around a 6in. gear wheel. At the face of each pair of magnets is placed an armature extending to the gear wheel. Every second the current from the main line to 252, Broadway, brings into circuit 64 cells of a local battery, energising one pair of magnets and starting the wheel, the impulse then affecting each pair in rotation, and distributing the pull or load very evenly. The armatures controlling the movement of the gear wheel are adjusted so that there is no jump when they act, the clock running with a smooth steady action. There are three gear wheels which turn a long vertical rod; a worm at the top of this rod works on a hollow gear wheel turning the hands of the clock. The dial is painted on the wall of the building, and the hands travel around in front of it as in the ordinary clock. This gigantic clock is intended to serve as an advertisement.

THE form which an electro-magnet should have depends upon the nature of the operations it is used to perform. A design of an electro-magnet which is very suitable for some purposes is not suited at all for others. Supposing it is desired to make an electro magnet which shall be capable of rapid changes of strength, or possess small residual magnetism, it should be made of very soft Norway or Swedish iron, and have the form of a short, stout bar, rather than a long, thin one. The reason for this is that the ends or poles of a magnet exert a depolarising action upon the mass of the interior of the magnet.

SCIENTIFIC SOCIETIES.

ROYAL ASTRONOMICAL SOCIETY.

THE first meeting after the vacation was held on the 12th November, Mr. J. W. L. Glaisher, president, in the chair.

Mr. Knobel drew attention to some paper prints from stellar photographs, which had been sent to the society by M. Gotard. Amongst them was a photograph of the Ring nebula in Lyra, showing the decrease in brightness at the extremities of the major axis of the ellipse. The exposure was made in 70 minutes. There were also photographs of the Horseshoe nebula and the Dumb-bell nebula.

Father Perry read a paper by Mr. A. Cortis, of Stonyhurst, on "Bands Observed in the Spectra of Sunspots." He said we found that a great deal of attention had been given both at Greenwich and South Kensington to observations of sunspot spectra on the violet side of D. Mr. Cortis and I therefore determined to confine ourselves to working at the red end. There is both selective absorption and general absorption, and besides bands in the spectrum, the solar lines are sometimes darkened and sometimes broadened, being winged on either side, though the central dark line is not widened. We have observed eleven bands at the red end of the spectrum at Stonyhurst, and have kept our attention especially fixed upon two—6,380 and 6,383. When you move the slit away from the spots you immediately lose these bands in the spectrum of the photosphere. You get complicated spectrum bands only in the spectrum of the spots. With regard to both these bands 6,383 and 6,380, they have been on one or two occasions split up into about three lines. None of the bands observed by us have any corresponding lines in the spectrum of the photosphere, with the exception of 6,380; but they have nearly all of them corresponding bright lines in the spectrum of the photosphere, as identified from Prof. Young's catalogue of such lines.

Mr. Ranyard: With regard to the observation of bands in the spectrum of sunspots, one is likely to be deceived by the mere alteration of illumination. My faith in what I had thought previously to be veritable broadening of lines and bands in sunspot spectra has been very much shaken by an experiment recently shown me by M. Thollon. While I was looking at the solar spectrum he placed a small object at a little distance in front of the slit, so as to throw a shadow on the slit, a shadow which was almost total at the centre, but had a penumbra on either side. It gave rise to a band across the spectrum which I immediately took to be the spectrum of an ordinary sunspot. In the dark band the lines appeared winged and thickened, and quite different from their appearance in the photosphere spectrum. I have recently repeated the experiment near to a sunspot, and I would advise others to do so. It has quite shaken my faith in the objective character of many of these winged lines and bands. I do not wish to state that there is no change in passing from the ordinary solar spectrum to the sunspot spectrum, except a change of illumination; but the evidence with regard to any particular line or change should be carefully examined in conjunction with the solar spectrum, seen under fainter illumination.

Mr. Maunder: Some years ago, in observing the spectra of sunspots, I found a number of shaded bands in the neighbourhood of the *b* lines. I have not examined the red region sufficiently carefully for bands; but I have no doubt of their existence. I do not think that those near little *b* can be due to a darkening of any portion of the solar spectrum. They were very distinct, and in their main characteristics resembled very much the bands described by Father Perry—that is to say, for the most part we were unable to see any lines corresponding to them in the solar spectrum, though occasionally we would be able to trace the band as corresponding with a very faint line. I believe that none of these bands are given by Angstrom; but one or two are given in Fiévez's chart, and on one or two occasions I have just been able to break up some of the bands into two or three fine lines, so that they presented just the same characteristics as the bands observed by Father Perry.

Mr. Isaac Roberts read a paper on "Stellar Photography," illustrated by a number of photographs. Amongst them were enlargements from negatives taken on the nights of the 23rd, 24th, and 25th of August of a region in the constellation Cygnus, which corresponds with a region photographed by the brothers Henry with their 13in. refractor, enlarged copies of which photographs the brothers Henry have presented to the Astronomical Society as a specimen of the great number of stars which may be photographed with their instruments with an exposure of 60 minutes. The enlargements made by Mr. Roberts were on the same scale as those of the brothers Henry. Mr. Roberts's photographs were taken with a 20in. reflector, and enlargements from plates exposed for 30 and 60 minutes were shown. In order to compare the photographs Mr. Roberts had counted the number of stars shown on corresponding square inches of the enlarged copies. On his own photographs he had counted on three square inches 109, 93, and 70 stars respectively, and on the corresponding square inches of the enlarged copies from the brothers Henry's photographs there are 59, 64, and 41 stars respectively, giving an average of 91 stars per square inch on the enlargements from his own photographs, and an average of 55 stars per square inch on the enlargements from the photographs of the Brothers Henry. He estimated that about the same number of stars were shown on his plates exposed for 30 minutes as on the plates exposed by the Brothers Henry for 60 minutes. Mr. Roberts also showed some original negatives of the Pleiades group, showing clearly traces of nebulæ surrounding the stars Alcyone, Maia, Electra, and Merope. The photographs of the Brothers Henry, which were exposed for three hours, showed traces of nebulous light round only three of these stars. On a negative of Mr. Roberts's, obtained on the 23rd Oct. with an exposure of 89 minutes, all the above named four stars were seen to be nebulous, and traces of nebula were seen extending through the whole of the Pleiades group. A negative, taken on the 24th of October, with an exposure of three hours, confirmed the nebulosity about all the four stars, and showed a still greater amount of nebulous light extending in streamers and fleecy masses so as almost to fill up the spaces between the stars, and extending far beyond them, as if the group were the centre of one vast nebula. Mr. Roberts said that he was awaiting with watchfulness for a clear interval during which he could make an exposure of the group for five hours.

Mr. Common said: I am extremely gratified with these photographs, not only because they have been taken in England, but because they have been taken with a reflector. In the early days when I took up photography, I came to the conclusion that if any good work was to be done it must be done with the reflector, because it brings the light of all parts of the spectrum to the same focus; and this is especially important now that the old collodion plates are not used, for the bromide plates are sensitive to a much larger region of the spectrum. Mr. Roberts stated that in his photographs the stars are not represented by sharp hard discs, as in the photographs of the Brothers Henry; but this is chiefly due to the method of copying they have employed. In some photographs taken direct from their negatives with which they have favoured me, the gradation at the edge of the star discs is distinctly to be seen.

Mr. Ranyard said: Mr. Roberts has not mentioned the beautiful way in which even the diffraction rays due to the supports of the photographic plates are shown round the images of all the larger stars down to the 3rd or 4th magnitude. There are eight rays, and on inquiry of Mr. Roberts I find that besides the three watch-spring supports which give rise to the six rays usually seen in reflectors, there was a focussing rod, which gives rise to the two other rays; the stellar point in the centre of the rays is much smaller than in the Henry photographs.

Mr. Knobel said: Mr. Roberts has been comparing his photographs with those taken by the Bros. Henry some time ago. I have recently been comparing some of the Henry photographs with those taken by M. Gotard, and I find that in the recent photographs of the Henry's there are a great many more stars than in the earlier ones.

Mr. Maunder gave some account of the observations of the recent eclipse in the West Indies. He said: I am not prepared with any account for the society. We divided into several parties when we arrived at Granada, so that if the weather was unpropitious in one part, it might not be so in another, and the precaution turned out to be very necessary, for Mr. Lockyer, who went to Green Island, saw nothing. Mr. Schuster, Capt. Darwin, and Prof. Thorpe went to the east coast of Granada. Mr. Turner and Prof. Tacchini to the North, and I went with Father Perry, 20 miles further North, to the Island of Cariaco. On the morning of the eclipse it was very fine at our station up to sunrise—almost immediately after sunrise heavy banks of clouds came up; before the first contact the sun was hidden, and we had a small shower, which obliged us to cover up our instruments; but fortunately before totality the cloud cleared, and the sun passed into a clear portion of the heavens. On the east coast of Granada Captain Darwin obtained a number of photographs of the sun both before totality and during totality. His idea was to test Dr. Huggins's method of photographing the corona in full sunshine, and as far as yet appears, his results negative the idea that Dr. Huggins has been successful. Dr. Schuster got two spectroscopic photographs; one with the slit radial, and one with the slit tangential—both will be useful. Father Perry tells me that Dr. Schuster also got five photographs of the corona; but I have not seen them. I myself got seven photographs of the corona, and I think that five of them are good. I was not successful with the photographs of the spectra. Professor Tacchini made some very interesting spectroscopic observations, perhaps the one of greatest interest is that the prominences we see with the eye during a total eclipse are not precisely the same prominences we see by the spectroscopic method during full sunshine, for the upper portions of the eclipse prominences give a continuous spectrum. I, myself, did not see any red colour in the prominences visible round the sun—to me they appeared white; but it may have been that the red region was so small in comparison.

Major-Gen. Tennant read a paper on the orbit of Comet 2 of 1883. Mr. Bryant had calculated an orbit of this comet, which was elliptical, and according to him gave a period of 90 years. On going over and comparing the observations of this comet by several observers, he found that they did not correspond satisfactorily with the normal places which had been used. After making several assumptions, he was inclined to think that a period of 2,000 years would be nearer the truth, or that the orbit might be parabolic.

Mr. Ranyard read a paper on the form of the area in the heavens from which the meteors of Nov. 26, 1885, appeared to radiate. He said there were many observers of this rich shower, and almost all agree that the meteors did not radiate from a point, but that there was a radiant area of some considerable extent. I did not observe the shower till well after its maximum; but from 40 or 50 meteors whose paths I observed and was able to trace back upon the heavens, I thought that the area from which they radiated was elliptical. I mentioned this to Col. Tupman, and he told me that in the chart of paths he had laid down the radiant area was distinctly elliptical. We agreed at the time that it was merely a coincidence, as we did not see any reason for such an elliptic area. When Col. Tupman described his observations at the meeting of this Society, he stated that the longer axis of his elliptic area lay north and south. This struck me as an additional coincidence with my own observation; but I did not think seriously of it till a few weeks after, when I saw a letter from Prof. Young, which was published in *Nature*, in which, after describing his observations, he says that the radiant was not a point, but rather a region about 4° long, north and south, by 2° wide. I wrote to ask him further about his observation, and he replied that the radiant region was elliptical, perhaps a little larger than he had at first estimated. Recently, during a visit to the Observatory at Nice, M. Perrotin showed me a map, on which he and his assistants had laid down the courses of 60 or 70 meteors they had observed on the night of Nov. 26. I at once saw that the paths did not radiate from a point, and without telling M. Perrotin of the other observations, I asked him to draw a contour line round the area of radiation. Both he and M. Thollon, who was present, drew elliptical curves with the longer axis, north and south, or rather inclined 10° or 12° to the west of the north point. There, therefore, appears to be some very definite evidence that the paths of these meteors *did* radiate from an elongated area with its axis north and south. I have been thinking over what can be the physical cause of such an area. If the paths of the meteors were all parallel, they would appear to meet in a point. This shows that at all events the paths within the earth's atmosphere are not parallel. It has been suggested by those who, like Sir Stawell Ball and Mr. Proctor, believe in the ejection theory of meteors, that if they were ejected in slightly different directions originally from the earth, they would not return moving in parallel paths. But if their paths outside the earth's atmosphere were not parallel, their orbits and their periods would be so very different, that they would not come up to the earth again in a single swarm. I am therefore inclined to assume that their paths in space before they encounter the earth's atmosphere are all parallel; but that, by reason of their irregular shapes, they are deflected into slightly different directions after they enter the earth's atmosphere usually before they have had time to become luminous, though there is some evidence that such deflection or "skidding" from their original course sometimes takes place after they become luminous. Prof. Newton, Mr. Hopkins, and, I think, Col. Tupman, have noticed meteors with curved paths, and I have on two occasions noticed such curved paths myself. In order to account for the elliptic area, it is necessary to suppose that there must be some arrangement of the longer axes of the particles in space which causes them to be deflected more to the north and south than to the east and west. I would suggest that if the particles are magnetic they would on coming up to the earth tend to arrange themselves with their longer axes parallel to the earth's magnetic axis. And in connection with this it is worth noticing that the axis of the contour drawn by M. Perrotin and M. Thollon, of which I have a tracing here, does not point due north, but some 12° or 14° to the

west of north, which about corresponds to the deviation of the magnetic meridian at Nice.

The meeting adjourned at ten o'clock.

LIVERPOOL ASTRONOMICAL SOCIETY.

THE second meeting of the sixth session was held on Monday, the 8th instant. The chair was occupied by Mr. R. C. Johnson, F.R.A.S. Ten members were elected and 33 candidates were proposed. Messrs. T. G. Elger, F.R.A.S., George Knott, LL.B., F.R.A.S., and A. Cowper Ranyard, M.A., F.R.A.S., were elected Associates of the Society.

A paper by Mr. K. J. Tarrant was read on the "Micrometrical Measures of Twenty-Five Double Stars." The study of double stars was, perhaps, less interesting than lunar or planetary work; but the more the subject was investigated the more absorbing it became. By this he did not mean the mere attempt to split double stars, but rather a systematic study of those pairs where a motion was suspected or had already been discovered. He knew of no more wonderful result than to discern for themselves that the great law of gravitation extended to the far-off depths of space. The micrometrical measurement of double stars required three things—a good telescope, a reliable micrometer, and an inexhaustible stock of patience; as, in the cases of close stars, the observation would have to be repeated many times before results of any value could be attained. It was, however, a most important undertaking, and ought to be of the greatest assistance to the computers of a future generation. An accurate knowledge of their previous positions would enable them to calculate with certainty the amount of the proper motion, and might possibly disclose other interesting facts. This knowledge they did not themselves possess; but it was their duty to provide it for others who followed in their footsteps.

In a paper on "The Masses and Distances of Binary Stars," Mr. J. E. Gore, F.R.A.S., said: When the parallax of a binary was known, and the elements of its orbit satisfactorily computed, it was easy to find some of the masses of the component stars in terms of the sun's mass, and the real dimensions of the orbit. The parallax of a few of them had been ascertained. First, there was the famous binary star α Centauri, which, as far as was known, was also the nearest star to the earth. From its orbit, computed by Dr. Hind in 1877, combined with a parallax of 0·928″, he found the mass of the system = 1·79 times the sun's mass, and the semi-axis major 23·49 times the earth's mean distance from the sun. Assuming the latest elements found by Dr. Elkin (α = 17·50″, and period = 77·42 years), and his parallax of 0·798, he found the sum of their masses = 1·759, and the semi-axis major = 21·13 times the sun's mean distance. Second, η Cassiopeiæ. Dr. Dunér found for this binary a period of 176·37 years with semi-axis major = 10·68″. Combining these elements with O Σ parallax of 0·154″, Mr. Gore found the mass of the system = 10·722 times the sun's mass, and the mean distance = 69·35. The magnitude of the components was about 4 to 7·6; so they had a star of the 4th mag. with a mass about six times as great as that of α Centauri. The calculations of the elements of the well-known companion to Sirius were still more interesting, and there was no doubt that it was in rapid orbital motion round its primary, probably with a period of about 49 years. He had found the mass of this system = 71·63 times the sun's mass. Assuming the attraction of the companion to be the cause of the observed irregularity in the proper motion of Sirius, Auwers found that its mass must be about one-half that of Sirius; thus, we have the mass of a 10th-mag. star absolutely greater than that of the sun.

Mr. W. S. Franks, F.R.A.S., followed with a paper on "The Magnitudes of Double Stars," the determination of which he considered of great importance to astronomers. The old and well-known divisions into magnitudes was both vague and arbitrary, and, though it might never be entirely superseded, was certainly capable of much improvement. Sir John Herschel was one of the first to recognise the shortcomings of the prevailing system, and to suggest the better plan of indicating the exact brightness of the stars on a photometric scale. The reform thus inaugurated had been developed by Seidal, Wolf, and Zöllner on the Continent, Pritchard in England, and Pickering in America, each of whom used some special form of photometer. Undoubtedly the most valuable work of the kind was that by Prof. Pickering, published in Vol. XIV. Part I. of the *Annals of Harvard College Observatory*, both for the elegance of its methods and the completeness of the results. It contained the photometric magnitudes, expressed to the nearest tenth part, of 4,260 stars, being the mean results of some 100,000 separate measures. They might consider, then, that the true equivalent magnitudes of the naked-eye stars, for a certain epoch, had been satisfactorily ascertained and defined, though much still remained to be done before our knowledge of stellar magnitudes could be considered in any sense complete.

Mr. W. H. S. Monck, M.A., F.R.A.S., had framed some theories which he thought explained many of the singular appearances presented by the moon. The most noteworthy of these features were the absence of water and the great number of extinct volcanoes. Taken together, this was rather startling and quite unaccountable by terrestrial analogy, inasmuch as volcanic action on the earth appeared to be intimately connected with water. There was abundant indication of the former existence of water on the moon, and, he argued, this could not have been withdrawn into the interior—as had often been suggested—without provoking fresh volcanic outbursts. He rather attributed its disappearance to continual exposure of one side of our satellite to the heat which was radiated from the earth. It was more than probable that this heat, combined with an exceedingly low atmospheric pressure, had vaporised the water, which would thus be carried to the opposite, and colder side, and there condensed, if not frozen.—Mr. A. Newton Harris considered it unsafe to expect terrestrial occurrences to explain lunar appearances, which were in themselves quite beyond the range of our experience, at least, as regarded volcanic origin. At the same time, they naturally sought an explanation from analogy, and he had found what he thought to be the key in the "atolls" and coral formations of the South Pacific and Indian Oceans. In the clear water of those regions the sea bottom represented ring-mountains to perfection, and, granting a subsidence of the land, and a disappearance of the water, they would have a pretty near approach to lunar scenery.

In a description of some remarkable sunspots that were visible during the first fortnight in May, 1886, Miss E. Brown said that in many instances they were both unusual and striking. How immense this group of spots really was could only be realised by calculating its relation to the whole area of the sun's visible surface. According to Mr. Maunder, of the Royal Observatory, twenty-five of our earths might have lain side by side in this remarkable group. The group remained almost without alteration from the 2nd to the 11th of May, though towards the end of that period an alteration in its outlines gave warning that its dissolution was not far off. This, indeed, proved to be the case, for though some fragments reappeared during its succeeding revolution, their aspect was so different that it was doubtful if even it was the same group. Monsieur B. Lihou contributed an account of some observations which had led him to suspect a variation of light in the companion to Polaris. The idea was, he said, first suggested by the remarks of Mr. Isaac Roberts (*Monthly Notices* of the R.A.S. for Feby., 1886) with regard to the different times of exposure which he had found necessary to photograph this star. The duration of this exposure had varied from 4sec. to 60sec., and even, in one instance, to 15 minutes. This discrepancy seemed unaccountable, except by an actual variation in its light, and M. Lihou had commenced a careful series of observations in order to test whether this was the case. The observations were made with a 4in. refractor, and the variations were estimated from 9·5 to 10·5 magnitudes, the period being about 21 days.

In the second paper on "The Moon Surveyed in Common Telescopes," Mr. T. G. Elger, F.R.A.S., included the Mare Humorum and its surroundings. The 6th of next month would be favourable for reviewing that district, especially for studying the remarkable contour of the western border, and the curious ridges which traverse it. These latter deserved more than a passing notice, not only on account of the beauty of their form, but as exhibiting peculiarities of arrangement which tend to throw a ray of light on their origin. Their tendency to follow the curvature of the western border, like ripple-marks imprinted by the tide, was very noteworthy. This tendency was not confined to those on the surface of Mare Humorum, but might be traced in numerous other regions. The western border of the Mare, with its superabundance of complicated detail, included many remarkable objects, among them the incomplete ring Hippalus, and other smaller formations. The former looked as if it might have been breached by the pressure of an accumulation of the material within its borders, and which outspreads the Mare. The eastern side afforded still more interesting examples of these now incomplete rings than Hippalus. Lee and Doppelmeyer had been clearly destroyed on the side facing the Mare. In the case of the latter, when it was close to the terminator, distinct traces could be seen even with small apertures, of a former border in the shape of a low mound which extended across the opening. Mr. W. F. Denning, F.R.A.S., also contributed a second paper of his valuable series on "Telescopes and Telescopic Work."

SCIENTIFIC NEWS.

AMENDED elements and ephemeris of Comet Barnard are given in Dun Echt Circular, No. 130, from repeated and more extended observations. The time of perihelion is given as Dec. 16·4529 Berlin M.T.; π — ☊ 86° 31′ 42″; ☊ 137° 19′ 58·8″; i 101° 46′ 55·2″, mean equinox 1886; log. q 9·819841. The ephemeris reads:

	R.A.			N. Dec.	
Nov. 19	13h.	24m.	23s.	13°	38·0′
21	13	39	54	14	30·9
23	13	56	41	15	21 9
25	14	14	47	16	9·1

The position is south of Alpha Boötis, and the comet rises about 4 a.m.

Circular No. 11 of the Liverpool Astronomical Society, referring to the Rev. T. W. Webb's unpublished observations under date of Dec. 12, 1877, calls attention to the following note:—New pale orange-ruby, 7·5 mag., a fine, clear colour = O R4. 8 mag. W. Lies ± 4′ *s.p.* the ruby. Diff. from ξ and ν must be ± 47°. It lies 4m. *p.* 15′ N. from a star 6 mag., probably one in S.D.U.K. map ± 47° N. 0h. 36m. A single bad diffn. made ruby 5m. *f.* ζ, or 0h. 35″. The "6 mag." = + 47° No. 181. The "8 mag." + 47° No. 157. Hence we should have—

		h.	m.	s.	°	′	
From + 47° No. 181	=	0	32	24	+ 47	19·2	(1885)
From ζ Cassiopeiæ	=	0	31	6			"
From + 47° No. 157	=	0	30	50	+ 47	17·6	"

There is no star in Argelander here, nor could any red star be seen in this place with the 17¼ equatoreal on the evening of November 7th.

By the death of M. Paul Bert, France loses one of its eminent scientific men—one who had, however, devoted himself to politics of late years. He was born at Auxerre in 1833, and studied medicine under Claude Bernard, taking a doctor's degree in 1863. He devoted himself to research, and very soon attracted the attention of the scientific world by his papers, which led to his appointment as professor of the Faculty of Sciences, Paris, in 1869. With the advent of the Franco-German war Bert's pursuits were changed, but he still kept up some of his scientific work, and in 1875 received from the Institute the prize of £800 for his "La Pression Barométrique, recherches de Physiologie expérimentale"; and in 1877 was elected president of the Biological Society in succession to Claude Bernard. "The First Year of Scientific Knowledge," which we reviewed in No. 1088, is an excellent book for elementary schools, and has made the name of Paul Bert known throughout the whole of his native land.

The death is announced of Dr. Frederick John Farre, for many years physician to St. Bartholomew's Hospital, and at one time examiner in materia medica at London University. He edited Pereira's famous manual. Dr. Farre was in his 83rd year.

Dr. G. A. Fischer, an African traveller of some repute, died recently in Berlin, where he was awaiting the arrival of his notes and specimens from Africa.

It will be learned with regret that the health of Prof. Tyndall is not sufficiently restored to warrant him in undertaking the Christmas lectures at the Royal Institution. Prof. Dewar will, therefore, deliver a course of six lectures adapted to a juvenile auditory on "The Chemistry of Light and Photography."

Amongst the lectures to be delivered at the London Institution this session we notice that Sir R. S. Ball will deliver two on the "Astronomical Theory of the Great Ice Age," on November 22 and 29; Professor E. Ray Lankester, six on the "Elements of Biology," November 25, December 2, 9, 16, 23, 30; Dr. C. Meymott Tidy, three on "Chemical Action," January 6, 13, 20; and Professor S. P. Thompson two on "Electric Bells," February 10 and 17. On December 20, Mr. H. Seebohm will lecture on "Birds' Nests and Eggs"; on December 27 Mr. Eric S. Bruce on "War and Ballooning"; on January 17, Professor W. H. Flower on "Fins, Wings, and Hands," and on February 24 Mr. H. B. Dixon on the "Lighthouse Experiments at the South Foreland." The other lectures are historical, musical, and literary.

In No. 1,028, p. 295, Vol. XL., we gave an

account of some experiments carried out by Messrs. Sutton, of Reading, at the instigation of Earl Cathcart, with the view of regenerating the potato and discovering its original species. On Monday last a number of gentlemen, including Dr. Hogg, Dr. Masters, Mr. Shirley Hibberd, and other authorities in potato history, visited Messrs. Sutton and Sons' trial grounds at Reading to note the experiments, which have been very successful and satisfactory. It was agreed that the parent in the cross was not, after all, a true specimen of Solanum Maglia, but was a wild form of Solanum tuberosum of a distinctly different geographical origin from the variety which furnished the varieties commonly cultivated, and this wild form has been preserved for many years at Kew-gardens in a bed side by side with the plants of Solanum Maglia. Twenty-three plants were obtained in 1885, and the tubers set again in the present year vastly increased in weight, up to 122lb. from 15½oz. The cross is between the wild Solanum tuberosum and the variety known as Sutton's Reading Russet. In point of quality and shapely form they leave nothing to be desired, and reach a high standard of merit. Several other crosses have been obtained in this first attempt to introduce new blood into the potato, successful hybrids being bred from the wild species crossed with Walker's Regent, Paterson's Victoria, and other popular varieties.

Although the crop of tobacco raised by Messrs. Carter has not been sold in open market, it has been "cured" so successfully that it is considered to be worth from 6d. to 8d. per pound, and as the total yield is about 15cwt. from the three-quarters of an acre, that would show a value at the lower rate of £42, or at the rate of £56 an acre. At present, the other side of the account is not available; but such a return, if realised, would induce many to try whether tobacco cannot be raised with economy—though cultivation, manure, and "curing," no doubt, swallow up a very large portion of the sum that would be received for such a crop.

The Vice-Chancellor of Cambridge University has communicated to the Senate a letter received from the Attorney-General, to the effect that Mr. John Lucas Ward had left him the sum of £10,000 to be spent "in the promotion, without regard to sect or party, of scientific and literary research, or of either of those objects, in Cambridge or in the metropolis, or in both these places." After consultation with Prof. Huxley, Sir James Paget, and several others, a scheme has been formulated, and "The John Lucas Ward Fund" is to be devoted to the foundation of studentships in Pathology, open to males or females. It is also expressly set forth that studentships shall not be awarded as the result of a competitive examination; but the students are to be elected on the nomination of the Professor of Pathology—a stipulation which indicates the direction in which the wind is blowing in connection with competitive examinations.

A movement has, it is stated, been set on foot in Italy towards erecting in one of the principal towns an electrical crematorium. In this edifice the corpses will be instantly consumed by means of an intense heat caused by electricity. Various European cremation societies are reported to have despatched representatives to Italy to make inquiries as to the feasibility of the scheme, which it is expected will, if successful, soon replace the more elaborate methods now generally adopted. There does not seem any necessity to send representatives to Italy, as it is quite certain corpses cannot be "instantly consumed" by electricity.

The Artisans' Classes already started at the Royal Victoria Hall, Waterloo-bridge-road, S.E., are well filled, and some, we are informed, are in danger of being over-filled. A class in chemistry under Mr. W. P. Bloxam, and one in mathematics under Rev. P. H. Wicksteed, are also contemplated, if not already started. The fees are purposely made so low as to be merely nominal. Amongst the forthcoming scientific lectures we note that Prof. Rücker will discourse on the "Early History of the Earth and Moon," on Tuesday, Nov. 30; the Rev. W. H. Dallinger, President of the Royal Microscopical Society, will lecture on "Plants that Prey on Animals, and Animals that Fertilise Plants," on Dec. 7th, and on Dec. 14th. Prof. Boyd Dawkins will describe the "Introduction of the Arts into Britain."

Prof. Wrightson, of the College of Agriculture, Downton, can readily believe that there is a loss of two or three millions to the country through the ravages of the warble or ox botfly (*Œstrus bovis*), but thinks it might cost two or three millions to protect the cattle in this country from the attacks of the fly. It should be remembered, however, that the loss is of annual recurrence, while the expenditure to prevent it would become less yearly.

The Annual Report of the Department of Mines, New South Wales, for 1885, shows that the Government of the colony is aware of the value of such work in attracting capital, and that the portion of Australia known as New South Wales is rich in minerals. The reports of the Mining Registrars on the Gold Fields of Victoria show a decline on the yield of gold for the quarter ending June 30, 1886.

The Case School of Applied Science, Cleveland, Ohio, which was endowed by the late Leonard Case with property worth two million and a quarter dollars, has been destroyed by fire, the actual loss being about 200,000 dollars. One would have thought that a school of applied science would have been made as nearly fireproof as possible.

M. Poskin uses chromic acid as a caustic; but points out to the Liège Medical Society that it is necessary to use great caution. He heats moderately a very small crystal on a silver probe to which it adheres as a dark brown coating. If a green oxide is formed, the acid loses its caustic power. Its action is neutralised by a weak solution of carbonate of soda.

In a paper presented to the Paris Academy of Sciences M. de Forerand says that glycerin is attacked in the cold by alkaline metals with the formation of a glycerinate and the escape of hydrogen. The fragments of the metal become coated with solid glycerinate, and if heat is applied the matter turns black and an explosion follows.

The Handicrafts Committee of the Manchester Exhibition, of which Alderman W. H. Bailey, President of the Manchester Society of Engineers, is the chairman, have done a wise thing in offering a special prize of £20 to the exhibitor of any handicraft process at work likely to be of utility and profit to cottagers. Anything that will help home industry must be a real national benefit.

The committee of the Penrith Literary and Scientific Society has decided to have a course of lectures on astronomy (illustrated with photographs and diagrams) delivered throughout the winter. Mr. William Peck, F.R.A.S., is to be the lecturer. The opening lecture of the course was delivered on Thursday evening last (18th inst.).

Engineers' Tools, Amateurs' Lathes, &c.—The Britannia Company, of Colchester, have issued a new catalogue of the tools and machines constructed by them. It is freely illustrated, and is printed in 4to. size on thin paper.

Piston Valves for Locomotives.—According to M. Ricour, piston valves in locomotives wear at the rate of $\frac{1}{25}$in. for 125,000 miles, whilst with the slide valves the same extent of wear takes place with one-sixtieth of the mileage. The wear of the valve gear is reduced in the same proportion. The effect in the consumption of fuel is shown by the returns made at Saintes Station for the year 1882, where on all engines worked with slide valves, the coal consumed per 1,000 tons conveyed one mile was 226lb. against 234lb. in the year 1884, when 30 out of 40 locomotives had been fitted with cylindrical valves.

New Propelling Appliance for Ships.—In No. 1,062, p. 479, Mr. W. Griffin gave a brief account of a new device for propelling ships. Messrs. Hughes and Griffin, of Bilston, Staffordshire, have recently obtained acceptance of a complete specification (No. 209, 1886) which can now be seen at the Patent Office. The object of the invention is to so construct and arrange a number of paddles for ships, that they may enter and leave the water feather edge after traversing nearly the whole length of the ship, by which device the "slip and back weight are entirely removed." It is impossible to describe the invention without diagrams, which are not yet published.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents. The editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, *332, Strand, W.C.*

All Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks, a vice from whence great inconveniences derive their original."—*Montaigne's Essays.*

REDUCING A STAR'S PLACE FROM A CATALOGUE: ERRATUM — THE LIVERPOOL ASTRONOMICAL SOCIETY'S JOURNAL—SATURN'S RINGS — COMPLETION OF THE OBJECT-GLASS OF THE GREAT LICK TELESCOPE—PATH OF A FALLING BODY THROUGH THE EARTH—THE EARTH'S DENSITY—A NOVEL PLANISPHERE—MOTIONS OF THE EARTH AND MOON.

[26490.]—"VEUTON VEOR" (query 60722, p. 183) will probably observe from internal evidence that letter 26440 (p. 213) was written in very great haste. Reading it through now in print, I find that I have, in the third paragraph, in some way absolutely inexplicable to myself, included the secular variation in Precession in R.A. and N.P.D. in the quantities to be added to the star co-ordinates to determine them for the date specified! and even taken out the proper motion wrong. The calculation should, of course, stand thus: Mean R.A. of γ Orionis on 1872, Jan. 1, 5h. 18m. 15·926s., mean N.P.D. at same epoch, 83° 46′ 6·190″.

+ 3·2158sec.
+ 0·0020
———
3·2178
14
———
+ 45·0492sec., and 5h. 18m. 15·926s. + 45·0492 secs = 5h. 19m. 0·973s. Similarly—

− 3·632″
+ 0·040
———
− 3·592
14
———
− 50·288, and 83° 46′ 6·190″ − 50·288″ = 83° 45′ 15·902″. With the substitution of these quantities, the rest of the paragraph containing the gist of the reply to "Veuton Veor's" question is perfectly correct.

The Liverpool Astronomical Society may indeed be proud of the first part of Vol. V. of their *Journal.* I am loth to indulge in those "caparisons" against which Mrs. Malaprop protested; but it is difficult to avoid contrasting the 40 pages crowded with matter of interest to the amateur astronomer, and excellently illustrated by facsimiles of some of the author's sketches, with the wretched little three-page number which concluded Vol. IV. Précis of some of the papers which appear will be found on page 169 of the ENGLISH MECHANIC for October 22; but in addition to these there will be found an essay by that skilled observer, Mr. W. F. Denning, on "Telescopes and Telescopic work," which the beginner may peruse with considerable advantage: a remark which applies equally to Mr. W. S. Franks's "Division of Astronomical Work." The incipient Selenographer too will derive both pleasure and instruction from the perusal of M. C. M. Gaudibert's description of the Lunar Crater Cassini and from Mr. T. G. Elger's "Moon Surveyed in 'Common Telescopes'"; while an excellent popular exposition of the accepted classification of variable stars appears by Mr. J. E. Gore. Then we have biographies of four of the members of the Society whom it has lost by death during the previous twelve months; after which appear short reviews or notices of the books, pamphlets, &c., added to the Society's library. This is a novel and very useful feature. These notices are in turn followed by "Astronomical Notes," correspondence, &c., and queries and replies conclude the part. I would fain hope that this mere glance at its contents will suffice to show every amateur astronomer who has not yet joined the Liverpool Astronomical Society, how much merely in money's worth the

members receive in excess of their trivial subscription, and what really valuable aid to the observer is derivable from the perusal of its publications.

In the *Bulletin* of the Californian Academy of Sciences for September there appears a paper on Saturn, by Prof. George Davidson, which is well worth reading by all observers of that marvellous planet. I especially notice this here because Dr. Davidson, employing an Alvan Clark Equatoreal of 6·4in. in aperture, on several fine nights during 1885-1886, saw Encke's division in Ring A quite clearly, definitely, and unmistakably, tracing it on one occasion of superlative definition about 120° at each end of the ring's major axis. I fail to see how an observation of this sort can be controverted—clearly, not by anyone saying that he has looked at Saturn with a big telescope, and has *not* seen the division. This is merely the old story of the Irish pickpocket who, on learning that two men would swear that they actually saw his hand in a man's pocket, volunteered to bring six witnesses to state on oath that they didn't see him! Prof. Davidson also contributes a paper on "Transits of the 2nd and 3rd Satellites of Jupiter," and on the Annular Solar Eclipse of March 5, 1886, but these are, perhaps, of less general interest.

Apropos, by the way, of California, I hear that Alvan Clark and Co. announce that they have, at last, completed the object-glass of the Great Lick Telescope. In the skilled hands of Professor Holden this mammoth instrument ought to produce results at once interesting and important. Let us earnestly hope, then, that our experience of the work done by certain other gigantic telescopes will not be repeated in the case of the Lick Instrument.

An invitation from Mr. York (p. 221) to reply to query 60334 has just caught my eye; but turning back to the original question, with that number appended to it (on. p. 23), and studying some more recent answers to it, it seems abundantly evident that it has drifted into a discussion as to the path of a falling body down a hole or well bored in the earth itself. Of course, if the axis of such a perforation were coincident with that of the earth—i.e., at the Poles—the falling body would follow a path which would be a prolongation of the plumb-line. If, though, we were making the experiment at the Equator, the body when set free would be moving eastward with the earth's Equatorial velocity, or more than 1,000 miles an hour. Hence its "angular slope from the plumb line" would be at a maximum at two places—one at the point whence it was dropped, and the other as it was passing the earth's centre. That it must describe an ellipse round that centre is shown in Tate and Steel's "Dynamics of a Particle," where it is proved that any body acted on by two forces, one of which varies directly as the distance from the centre, and the other is at right angles to the radius vector, will perforce do so. On turning back, I find this very clearly and correctly put by "Dubliniensis" on p. 157. Of course, the earth's centre will be in the centre, and not in the focus, of such ellipse, as it would be did the attractive force act inversely as distance². So much for the paths of bodies falling through the earth from the Poles or Equator. At any immediate point on the earth's surface with latitude λ, a body so let fall would pass outside of the earth's centre by a distance $= 260 \times \cos. \lambda$ miles, and would move in a plane passing through the earth's centre, and at right angles to the great circle of longitude drawn through the place from which it was dropped.

In connection with this matter, will "Vulcan" (same numbered reply, p. 221) forgive me if I point out that he seems to be a little hazy on the subject of the gain or loss of a pendulum at the bottom of a mine. The crust or shell of the earth which lies above the pendulum produces no effect upon it at all. Take the Harton Colliery experiment, in which it was found that the pendulum was accelerated 2·25 secs. per diem; in other words, that gravity was increased at the bottom of the mine by $\frac{1}{19190}$th part. But this must obviously be taken in connection with the density of the rocks forming the spheroid beneath the pendulum. Were the density of the crust through which the mine was sunk two-thirds of the mean density of the whole earth, the weight of a particle would be the same, both at the top and the bottom of the mine. Were the crust perforated by the pit more than two-thirds the density of the interior, the weight of a particle would be less at the pit's bottom than at its mouth. While, finally, if the density of the whole earth exceeded that of the shell in a greater proportion than this the particle would —as it was found to do—weigh more at the bottom of the mine than at the top. As a matter of fact, the components of the crust of the earth accessible to us have a density less than three times that of water, while the specific gravity of the entire spheroid is very approximately 5·7. Gravity varies directly as the mass and inversely as the square of the distance from the centre of the attracting body, and in going down the mine you approach the centre of a smaller but *very nearly as heavy* a spheroid as that from whose surface you started. Were the earth homogeneous, its mass would vary as r^3 (r being the distance from the centre at any given point below its surface); hence obviously the attractive force towards that centre would vary as $\frac{r^3}{r^2}$, or directly as r.

Inasmuch as "D. D." (reply 60622, p. 222) has failed in obtaining a patent for what (assuming it to perform what he claims for it) must be an invention as useful as it is ingenious, why does he not give the readers of the ENGLISH MECHANIC at large the benefit of an illustrated description of so remarkable an instrument? I am sure that our Editor would not grudge either the cost or space for the diagram or diagrams.

The statement found by "J. C. O." (query 60903, p. 248) in the *Encyclopædia Britannica* is approximately correct. The mass of the moon is only about $\frac{1}{82}$nd of that of the earth, and, of course, it is their common centre of gravity that revolves round the sun. Hence the earth's centre is displaced by a distance of some eighty-secondth part of her distance from the moon, or 2,912 miles. This causes a seeming slight advance and slight retardation in her path, with a period of half a lunation; and this movement she, of course, to a terrestrial observer, transfers to the sun, whose journey through the Ecliptic is apparently disturbed in the same way. This effect is even more perceptible on Venus when she is nearest to the earth. If "J. C. O." will connect a large and heavy ball with a small and light one, by means of a piece of string, and throw them up into the air, he will note how they will revolve round a point close to the heavier ball of the two.

A Fellow of the Royal Astronomical Society.

SMALL STARS NEAR VEGA.

[26491.]—As much interest attaches to these at present, arising from Messrs. Henry's photographs, I think perhaps the details of my observations, undertaken at the suggestion of Mr. Sadler, may be worth insertion, more especially as Mr. Tarrant does not appear to have had very clear skies, having only seen his smaller stars on one occasion. My first observation was July 12. Air thick and unsteady; diagram shows nine stars within 6′ of Vega. I had no other opportunity until Aug. 6: Air clear and steady; 11 small stars seen. Aug. 10: 13 stars seen. Aug. 24: Air unsteady; 14 stars seen. Aug. 25: Flaring air; two stars more seen. Until this time I had been working with a film $2\frac{1}{2}$ years old. It was little tarnished; but from removal of dust deposited from London air was much worn and scratched. On Aug. 31st I got new film. Aug. 31: Air not clear, but improved as night deepened; never good while Vega was in view; 19 stars were seen, while two previously seen were not picked up. This night I found two minute *comes* to β Cygni, which do not appear to have been noted before, one being closer than the bright pair (to the blue star), and I found *comes* at 160° 25′ $\pm$ to Σ 2491. This completes my observations of Vega. I, however, looked on Aug. 30, and failed to see more than 13 in all.

On Tuesday, Sept. 7, I tried Polaris with small apertures, and found the *comes* visible with $1\frac{1}{2}$in. and a single lens; but could not see it with any eyepiece at all. Air was not clear, yet *comes* was easy with single lens. I used a Steinheil solid e.p. on Vega, upon a 9in. mirror; power 275.

I think a query was addressed to me some six weeks ago. The querist will not think me uncivil in omitting to answer when I inform him, since September 29th I have been in bed dangerously ill, and have little prospect of attending to anything for some time.

E. Holmes.

THE WILSONIAN THEORY OF SUN-SPOTS—U CYGNI—B 75—V CYGNI.

[26492.]—I am sorry that it has not been possible for me before this to reply to the remarks which, in letter 26080, p. 525 of your issue for August 13, "F.R.A.S." makes upon the concluding paragraph, *re* the Wilsonian theory of sunspots, of my letter in the "E. M." for July 30. He is quite right in supposing that in the last few lines "29" is a mistake for "27" June, but is wrong in his interpretation of the drawings. He assumes that the sun's limb was meant to be on the *left* side of the spot; but in point of fact, as I find by looking at the original sketches, the limb was on the *right* side, and the spot, therefore, as I understood when I sent the drawings, presented phenomena *in accordance* with Wilson's theory. I have looked over my other drawings of solar phenomena, and find that they include instances of spots in accordance with, and spots in direct opposition to, Wilson's theory, as well as spots behaving in a manner similar to that of which "F.R.A.S." gives the drawing appearing in his letter. I intend to carefully examine and classify my sketches, some of which are pretty elaborate, and will send the results to "Ours," with, perhaps, one or two drawings from them. Meanwhile, I may note the fact I have mentioned above, that the series includes instances of all three forms of spot.

U Cygni.—This is so splendid an object that, after seeing it, one is inclined to wonder much how it came to be that it should have been left to Birmingham to discover it so late as 1870, and to wonder, too, why it is that we so seldom see observations of it. I do not remember ever noticing any observation of it recorded in the ENGLISH MECHANIC. I had looked for it several times before; but, in consequence of some mistake, I did not find it till recently, on Sept 10 last. I found the pair a truly superb one. The red star was a rich ruby, and the companion a fine blue—the colours were in themselves very fine, and the contrast gave them an added vividness. The red star was about 0·3 mag. above the blue one. The date of maximum given in the "Companion to the Observatory" was September 20. On October 31, I saw it again. The stars were about equal, the red one being perhaps just the brighter; but *both* stars looked rather fainter than before. The one was of the richest ruby, the other blue, though not of so fine a colour. I observed that night, however, that no blue star was very well seen—not even the *comes* to β Cygni. Can "F.R.A.S.," or Mr. Tarrant, give me any further information respecting this pair, and tell me whether anything is known as to whether or not it is physically connected? Is anything known of the spectra?

B 75.—I have succeeded recently in obtaining two observations of this star. The first was on the 27th of September, when I found the colour fine ruby, and the star of between the 7th and 8th magnitudes. On the 25th of October I saw it again, when the colour was ruby, and the mag. estimated at $7\frac{3}{4}$. Mr. Espin has kindly furnished me with some observations of the star, all of which agree among themselves, and with the above, closely, in respect of magnitude. As to colour, the earlier of the observations mention *deep orange*, the later *pale red*. Taken in conjunction with the above obs. of a *ruby* colour, does this indicate any progressive deepening of the tint? "Birmingham" attaches no note of his own to his entry of this star, but cites this from Schjellerup: "Chacornac (Bull. Mét., April 12, 1858) éclat terne et nébuleux, 7·5." Can those using large apertures say anything further about this peculiarity? No spectroscopic result is given in Birmingham—has any been obtained? The star can be easily found in this way. A star lies *n.f.* κ^1 Tauri, forming, with that star and v^1 Tauri a right-angled triangle. B 75 lies a little *n.f.* this star, and is almost pointed at by the line joining κ^1 with this latter. It is not in Proctor's Atlas.

The same night as Mr. Ward (letter 26455, p. 217) was looking at V Cygni I was looking for it, though without success similar to his. I looked for it because of finding in the "Companion to the Observatory," under date Oct. 15, "V Cygni M." It appears, however, from Mr. Ward's letter that the star was about this time at or approaching a *minimum* instead of a *maximum*, as there stated. It thus seems that either there is a misprint in the "Companion," or the elements employed in the computation of this date are seriously in error. Which is the explanation?

Glasgow. **S. Maitland Baird Gemmill.**

"HAS ENGLAND GONE UP-HILL OR DOWN DURING THE LAST FIFTY YEARS?"

[26493.]—I have a strong conviction that the doctrines of "A Socialist" are economically unsound, and I am quite sure he is utterly ignorant of any real grasp of the question about which he writes so flippantly. Before "A Socialist" goes further, I would commend to his attention an article entitled "The Labour Convention at Richmond," which appeared in a Canadian paper, *The Week*, on Oct. 21, 1886. If "A Socialist" will answer the questions asked in the article in question without prevarication or "withholding aught," and continue to advocate his Socialistic doctrines, formulating with less verbosity his position, I will do my best to show where and why he is wrong, with the sole stipulation that the arguments shall be over our real names.

C. H. W. B.

[26494.]—If "Socialist" can briefly show us a practical scheme for ameliorating the condition of workers (genuine workers) he will be doing a service. In the past, Socialists have, as a rule, been on the side of destruction and disorder, which produce stagnation in trade and consequent want of employment, and distress.

By all means let us hear of any good they have done in the past, and let us participate and cooperate with them in any practical scheme for benefiting workers in the future. In order to see something practical before us, let "Socialist" give us a scheme for elevating the needlewomen and release them from the grinding system under which they work.

I belong to the class which, perhaps, he would

exterminate, although it is my aim to pay as good wages to my men as competition allows. Let "Socialist" point out how competition is to be superseded, for that is the problem. Selfishness prompts men to aim at large profits and large returns, and these are not often obtained without doing what is so much to be deprecated, screwing down wages.

The working classes may one day make a world-wide combination, and then they may demand what is a fairly just division of the profits, and I am sufficient of a Socialist to say that I shall rejoice to see the day; but one country cannot do this, or foreign competition will at once destroy our home and export trade.

A Worker and Capitalist.

[26495.]—No doubt it would be matter for general satisfaction if the various unpleasantnesses referred to by "A Socialist" should disappear. I gather from his letters that he attributes their continued existence to some fault on the part of one section only of the community—viz., the capitalists. I have conversed with others holding similar views, but have always been disappointed to find that they were unable to propose any intelligible new plan or general principle on which things might go better. Perhaps I have been unfortunate in my teachers.

Will "A Socialist" say what he proposes as a comprehensive substitute for our present arrangements, taking into account two great principles, the truth of which, I presume, he will not deny, viz.:—

1. The greatest good of the greatest number.
2. The survival of the fittest.

Though, indeed, the first would be enough in itself, as a little consideration will show that when we consider future as well as present generations, the second is included in it.

I do not ask "A Socialist" to trouble about the mere patching up of details such as might be, perhaps, done by regulating hours of work, or rate of remuneration for any particular employment; or methods for relieving certain persons from the necessity of parting with portions of their clothing for inconvenient periods; or for abrogating any particular one of the various pecuniary miseries we can all see around us; but it would be of interest to have an outline of the general principle or plan by which these things could be obviated, and the division of the joint product of capital and labour made permanently satisfactory.

Belfast. **J. Brown.**

[26496.]—If the moderate letters to which "Socialist" replies deserve to be called "howls," what word shall fitly describe his own astonishing farrago of wild abuse and reckless assertion? Let me suggest to him, that what I may call the "Yah! Boo!" style of controversy, though perhaps cogent among, and to be excused in, the aborigines of the gutter, is scarcely dignified, still less convincing, even when addressed to "such liars, swine, and idiots" as are capitalists, according to "Socialist."

But before going further it would be most desirable to have from "Socialist" a clear definition of the expressions "the people," "the true worker, or working man," and "the capitalist." These slip very glibly from the lips of Socialists and their congeners, but are often used (especially the last, which is generally coupled with an abusive epithet) in such a manner as to betray a very hazy idea of their true meaning. Take my own case, for example: I earn my living, and, moreover, earning somewhat more than sufficient for my present wants, have invested that surplus. Am I, then, a "true worker," or a (more or less) "bloated capitalist?" Do I belong to the "real people" or not, and if not, why not?

I fear I do not, since, according to "Socialist," the "real people" are those who cannot afford watches, &c., and who pawn their clothes. But why are such folk more deserving of the name of "the real people" than as many dukes or greengrocers?

If "Socialist's" theory, that the man with dark prospects saves, be correct, surely the lessening of bank deposits should be a cause of rejoicing rather than lamentation, since it implies that the prospects of the savers are brightening. In any case, though, it should be good tidings for Socialists, for it shows that there are fewer "swinish," &c., capitalists, slothfully absorbing their "plunder" of 2½ per cent. Why, by the way, is it more "plunder" for one man to earn a wage by hiring out his money, than it is for another to do the same by hiring out his labour?

As to tram-men. Will an artisan give a penny for a box of matches when he can buy a similar one for a halfpenny, even though he knows that he latter can only be sold at so low a price through the maker being paid starvation wages? And if the artisan is justified in so doing, is not the tram director equally justified in laying out his money to the best advantage? Indeed, the director is the better justified of the two, since *he* is not spending his own money only, but that of others who have trusted him. I quite admit that tram-men only earn a low wage, but "Socialist" must remember that they only give in return low class (*i.e.*, unskilled) labour, a commodity which, thanks to pseudo-free trade and similar blessings, is a drug in the market.

It seems to me that the two chief rocks on which Socialists split are—1st, their ignoring of the fact that headwork, which can be only supplied by the minority, earns, as it deserves, a higher wage than handwork; and, 2nd, their assuming as a fact the fallacy that all men are physically and mentally equal.

Faber.

[26497.]—Your correspondent, "A Socialist," is wrong when he says his "capitalistic opponents are *evidently* badly hurt," and we are quite as much entitled to consider his letter a "ludicrous howl." Every point he raises is perfectly answerable to any reasonable, enlightened mind.

A man has £2,000, and invests this amount in the tramways and is able to get a dividend of, say, 10 per cent. This would give him an income of £200 per year. This man would be a "capitalist." But if this man has instead to live on, say, only £100 a year out of his £2,000, he would in 20 years be a beggar. "A Socialist" objects to a man taking the former position, and certainly cannot wish to see him in the latter state, of which there are so many, unfortunately. For, if all took this latter form of living, there would soon be no employment for the thousands who, on the tramways, &c., live as servants to "capitalists." Should all become socialists hereafter, one man will always strive to be richer than his neighbour. Equal wealth is impossible.

"A Socialist" *only* shows that the savings-banks have 8s. 3d. less than in 1861, he does not raise the question—whether the "£2,670,000" (and perhaps a greater sum) is being more usefully employed in trade and enterprise. His 8s. 3d. is no fact until he has settled this point.

Then, with regard to the population of Ireland, "H. G. E." is correct in taking the last few years as between 1871 and 1881, for he has the results of the census, which are facts. We cannot talk properly of the few years since 1880 until after the year 1891, when the new census will have been taken.

The case of "A Socialist" is not very strong if he cannot put it before the "E. M." in a more practical form than in his letter, which is not of the tone your readers most admire, neither businesslike nor amusing.

J. P.

[26498.]—Your socialist correspondent, like a good many other people, sees things his own way only. I am not learned in Socialistic views; but it appears to me that he does not consider a class which certainly exists to a pretty fair extent in this country, and of which I may take myself as an average example. Coming of a poor family I left school at twelve years of age to work for my living, and thirty-five years ago there were no restrictions as to time of work. I was kept at it from 6 in the morning until 8 or 9 at night. I never owned sixpence (until I was over 20 years old) which was not needed for food, clothing, and lodging, but succeeded, by the aid of free libraries, in obtaining a fair theoretical knowledge of chemistry, electricity, and engineering, which were utilised in my daily work. I never needed a day's work, never asked for a situation, and at the present time may perhaps be classed as a bloated capitalist, employing about two hundred men and boys, each earning more money than I did myself, and working little more than half the time. Out of the number I employ, some few have worked to educate themselves, and are in positions of trust with good incomes, but not one in a hundred of the juniors seems to have the slightest idea of educating and improving himself.

A large part of my capital has been made by my own hands, working at the bench, and I know workmen at the bench who can command very high rates owing to their exceptional skill. If I can obtain at the bench £5 per week and spend one, I must end as a capitalist, and all the Socialism in the world cannot prevent it. If I, like others I know, earn £5 per week and spend it all, it needs only a little reverse to make me a bankrupt, and then I ought to become a Socialist and claim the spending of the money earned by the man who does not spend it himself. A community of goods, like a community of wives, is, from all past experience, bad for the world and bad for individuals, doing away with all stimulus for special skill and exertion, which is the soul of all advancement.

Not a Socialist.

[26499.]—Will "A Socialist" (26474) solve the following problem? He himself admits the decrease in population and material prosperity of Ireland, and the chronic complaint of Irish agitators is that capital is not invested in Ireland. If, then, capital brings all the evils in its train that "A Socialist" contends it does, how is it that Ireland (free from the curse of "capitalist greed," &c., &c.) should be still going down-hill, and her people emigrating to lands where capital is more abundant?

If Socialists would indulge in a little less vapid froth, and examine such instances as I have mentioned above, and would try and discover how workers without capital—i.e., reserve labour—could undertake any work—e.g., railway and canal construction—that gave no immediate results, perhaps they might discover that the "impudent capitalistic libellers" are not the only ones who have still something to learn.

I also notice that in "A Socialist's" letter he first states that the "Darker a man's prospects are the more he saves"; then goes on to prove that men are saving less, then laments the fact. Apparently a little logic, or, if that is not necessary, a little more humanity, might be also added, while "A Socialist" is acquiring the elements of political economy.

F. W. W.

[We are deluged with letters on this question which we cannot insert. The controversy has already been carried utterly out of the bounds which limit discussion in this journal, and we must at once stop it.—Ed.]

ORGAN WINDCHESTS.

[26500.]—In reply to the letter by "C. H. D." (26472), I have much pleasure in giving my opinion upon the windchest alluded to. In principle the windchest is good; but it is open to grave question if the mode of its construction is satisfactory. Many windchests have been devised on the same principle—namely, furnishing each pipe with a special valve or pallet, doing away with all sliders, and bringing on the stops by simply admitting the wind into their respective chambers. In nearly all instances, the difficulty of accurately adjusting the numerous valves, and the heaviness of touch caused by the necessity of opening so many valves at one instant, have proved fatal objections to the adoption of such windchests. So far as can be seen from the drawings and descriptions given on pages 414, 525, and 597, Vol. XXXII., I am clearly of opinion the same objections will obtain in the windchest alluded to by "C. H. D." Supposing a department—Great, Choir, or Swell—contained only six stops, it would be necessary for every key to push up (against the pressure of the wind) six circular valves, varying from 1¼ to ½in. in diameter. The touch, under these circumstances, would be extremely unpleasant; on first touching a key, considerable pressure would be necessary to unseat all the valves connected with it; afterwards, almost all resistance would cease, and the key would go down with a jerk. Nothing is more disagreeable in an organ than a jerky touch. There can be no question as regards the advantages of doing away with the sliders and their attendant evils, and supplying each pipe independently with wind; but the means proposed of doing all this, in the windchest in question, are anything but perfect. This windchest was invented by Herr Walcker. A writer speaking of it remarks:—"It can be seen at a glance that the mechanism necessary to control so many little valves must be complicated and liable to derangement from atmospheric changes, &c., and that it is probable that the touch may be found to be quite heavy, owing to the organist having so much mechanism to put in operation."

The only perfectly satisfactory windchest on this principle is that known as the "Roosevelt Patent Windchest." In it there are no sliders, and every pipe has a separate valve, as in Walcker's invention; but all complicated mechanism is rendered unnecessary by the wind in the chambers being made to open the valves of the pipes. All that each key has to do is to pull down a small disc-valve, of about 1¼in. in diameter, against the upward pressure of a light pallet spring. By simply pulling down this disc-valve, twenty or more valves, admitting wind into the same number of pipes, are instantaneously opened. So perfect is the contrivance that the most rapid repetition is secured. With reference to this, it has been justly said by the inventor of the windchest, that the "paramount achievement, however, is the acquisition of *repetition* to a degree of perfection never before obtained in an Organ, and equal to that of the most perfect pianoforte." Another great advantage lies in the fact that the use of this windchest "effectually supersedes the usually complicated employment of the pneumatic lever, as it relieves weight of touch, even in the largest organs, with equal efficacy."

Returning to the Walcker windchest, alluded to by "C. H. D.," I may say that I consider it altogether unsuited for the Chamber Organ.

G. A. Audsley.

CHAMBER MUSIC AND MUSICAL INSTRUMENTS.

[26501.]—I cannot help feeling gratified at the many kind words of approval which have appeared in your correspondents' letters with refer-

ence to my "Notes on the Chamber Organ," and, now, it is specially gratifying to have the support of our good friend, "Country Solicitor." At one time I firmly believed he was so Mustelified that he could never be induced to believe in anything of the pipe organ species; but wonders will never cease even in this non-miraculous age. "Country Solicitor," in his last letter (26485), expresses a wish that, after so much pleasant correspondence, I should give, in your columns, my opinion on the "Mustel Organ," and on his instrument in particular. With your kind permission, Mr. Editor, I shall have much pleasure in doing so.

My opinion might be summed up in this brief sentence—the "Mustel Organ" is the king of all harmoniums or instruments of the free-reed class; but I am afraid so short and dogmatic a statement would neither satisfy "Country Solicitor" nor the rest of your musical readers. It has been my happy privilege to hear "Country Solicitor's" "Mustel" under his own consummate management; and I can assure you it was a musical treat of a very high order. As I listened, I realised that it was one thing to *possess* such an instrument, but quite another thing to be able to *play it as it ought to le played.* "Country Solicitor" has achieved a mastery over all the peculiar powers of the instrument which, it is quite safe to say, very few executants could, under ordinary circumstances, hope to attain. It is evident, notwithstanding certain defects and shortcomings, inherent in instruments of the harmonium type, that the "Mustel" is a remarkable instrument, capable of almost limitless powers of expression, and *nuances* and varieties of tone colour of surprising character; but it is also evident that great skill, practice, and natural musical talent are necessary to the satisfactory development of its capabilities on the part of the performer. If there is any fault to be found with the "Mustel" in this matter of expression, it lies in the fact that it lends itself to, if it does not naturally provoke, a weak and sentimental mannerism or style of playing. Those who possess or may in the future possess a "Mustel" will do well to bear this in mind; for nothing is more wearying to the listener, or less artistic, in a musical sense, than an exaggerated expression and a restless sentimentalism.

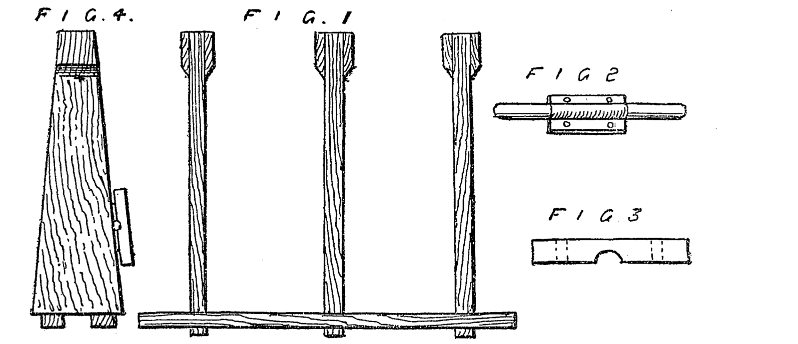
As all the peculiarities and features of the "Mustel" have already been fully described by "Country Solicitor" in these pages, it would be out of place for me to recapitulate them here. I need only give my testimony to the almost marvellous refinement and delicacy which characterise the tonal scheme of the instrument; the rare artistic skill which is displayed in every detail, as well as in the general conception of its structure; and the perfection of the several appliances placed at the disposal and under the perfect control of the executant. In all these respects the "Mustel" stands alone amongst all instruments of the harmonium class.

There cannot be two opinions as to the perfect suitability of the "Mustel" for both solo and concerted chamber music. So thoroughly do I recognise this suitability, that did I not possess a true Chamber Organ I should most certainly acquire a "Mustel," in preference to any other reed instrument of European or American manufacture known to me. **G. A. Audsley.**

ORIGINAL ELECTRIC EXPERIMENTS —AN IMPROVED ARRANGEMENT FOR A COMPOUND WIMSHURST MACHINE.

[26502.]—Upon looking up Mr. Wimshurst's "Few Practical Hints, &c.," on p. 201, No. 1,076, of Nov. 6, 1885, I find I am at variance with him upon some points. I think, then, he teaches that there is one angle or position upon each of the discs at which the best effects may be obtained. Now there is no reason, electrically speaking, why said brushes may not be placed, one pair perpendicularly, and the opposite pair horizontally, or in any other position so long as they are at right angles to each other. The only considerations coming into play are, Where is it most convenient to place your conductors, and also where are the bands to be placed? Next, I find that if the brushes are properly fixed, the machine, as might naturally be expected, works precisely as well whether it be turned to the right or left, but of course the place where the most electricity is given off, will not be the same. Then, as to the said brushes, there is no advantage gained by connecting them directly to the axle, being connected to any part of the framing answers equally well; more than this, we may remove them, and substitute four Leyden jars with a jump of, say, $\frac{1}{8}$ on my 24in. discs. Of course these jars must be provided with brushes.

Looking at the details of the compound machine figured upon page 192, of October 29th, 1886, it occurs to me that the bosses are too short to allow the bands to be sufficiently insulated from the discs. They are marked as $1\frac{5}{8}$, and with the position of brushes in the drawing as shown they would assuredly abstract a large quantity of the



electricity. As a proof of this, I may mention that if two sheets of glass be placed one over the other and separated—I cannot say just now how far, but certainly at three-quarters of an inch—and slips of foil laid upon the top sheet so that they almost touch at one end of each, if a rubber be applied to underside of the bottom sheet, it will be found that the electricity will pass from one to another in order to keep its original place of production opposite to said rubber.

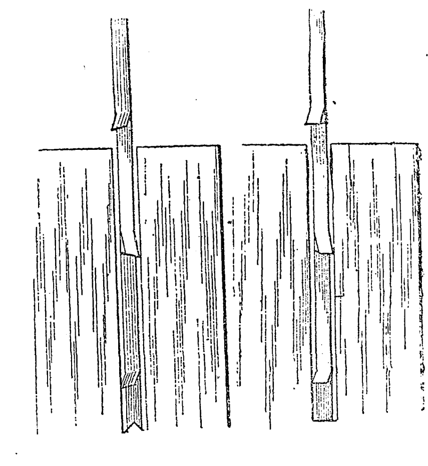
I conclude that a brush may be considered as a miniature rubber. I find that when any of these discs are used for a certain time, that there is a deposit formed upon the glass along the brush tracks which requires to be cleaned off, and I don't see how this could be conveniently done whilst the plates are so close to each other. I will now describe the nature of my proposed improvements—say, in this instance, for 19in. plates. Fig. 1 represents a portion of the baseboard, with three standards to carry four discs, any multiplication to be carried out in a similar manner. Fig. 4 is a side view of one of these standards, the top thickening pieces to be of, say, baywood, and the remainder, say, pine. Fig. 2 represents a malleable piece of cast iron similar in shape to a butt hinge, but solid enough to be bored through its length, so as to take the steel rod, which being turned up a shade larger it can be heated and shrunk on. The four screw holes are to adjust it upon top of the centre standard; the two outside castings will only require to have the rod projecting upon their inner sides. Now, I consider that $2\frac{1}{2}$in. is the shortest length the boss ought to be, and would incline to say 3in. This mahogany boss is to have the brass tube fitted into it right through, the face for the glass to be turned perfectly flat, cylindrical in its length, and the V groove as near its opposite edge as possible, the steel rod to be turned to fit as truly as possible. Thus we avoid making any hole in the glass, which is such a source of weakness and of ultimate fracture; and we get a convenient means of taking out any required plates without the ticklish job of threading all upon one spindle, and we can get at them more readily to oil the same. The driving gear would be fixed as shown by wooden cleat, Fig. 3, on right-hand side of standard. The neutralising rods for the two outside discs could be soldered to a slip of sheet brass, having a hole so as to slide on to the steel spindle, and be secured in position by a small screw into the standard; those for the two central discs could be made like one T on top of another, attached to a suitable base, so as to screw to the base-board of machine, and I would recommend that these be placed vertical, so as to deliver the electricity to each sector whilst it is opposite a standard, as it gives none off at that time, as I cannot see any objection to having conductors (if they are to be used) of varying heights to suit the place where the best result is to be obtained. In this arrangement the base-board is assumed to be solid, with slots for the driving wheels to fit partly into, so as to get as long a band as convenient. If it were to be glassed around, it would require a slight modification in the outside standards. These drawings are not made to scale.

A., Liverpool.

THE SHAPE OF SAW-TEETH.

[26503.]—With reference to what is said on page 233 about the shape of saw-teeth, the following remarks, which I saw in an American paper, may interest some of your readers:—

"As to the filing, I have found that a splitting saw, if filed as near square across the saw as possible, gives the best results. It cuts freer, leaves the stuff smoother, and will keep sharp as long as a saw which is filed at an angle or fleaming. If you believe in filing the teeth at any angle with the axis of saw, let me show you something which perhaps you have already noticed and can explain to your own satisfaction. After you have sharpened your saw, take a piece of lumber and try it. After cutting in a little way, stop and see the shape of the end of kerf. The points of the teeth have cut ahead and left the wood in the middle of kerf, projecting back towards the saw (Fig. 1). What cuts away the wood that forms this point? It must of course be removed by whatever edge the tooth may have crosswise of the saw. With the saw filed as in Fig. 1, there cannot be a very thin edge, and consequently it won't be an edge that will cut wood, and as it will require some crowding to make it tear or bruise off the wood, won't the crowding tend to force the points of the teeth away from the centre of the cut, making the saw cut a wider kerf than it should, and checking the speed until it runs slowly enough for each tooth to be



heard as it enters and leaves the wood? I claim that the cutting edge of the teeth on a splitting saw should be as nearly as possible at right angles with the grain of the wood operated upon. This is accomplished by filing the saw square across, both the front and top of tooth, as in Fig. 2, which leaves every tooth with an edge or point like the edge of a chisel. For a cross-cut saw the points of the teeth should 'resemble the point of a knife, so as to cut off the wood at each side of the kerf.' The centre of the kerf will take care of itself now."

It will be seen that there is much to say, even in connection with the teeth of saws; but it seems to me that much depends on the kind of wood, as well as on the shape of the teeth, set, &c. What do your practical readers think of the matter?

E. A. M.

"HOW A BOY MAY RAISE A SOLID TON WEIGHT WITHOUT MACHINERY."

[26504.]—I have read with much amusement the letter under the above title, which appeared on p. 195, and I should like to put a question—"Where's the boy?" If a boy, or a man for that matter, can raise a ton weight, whether solid or not, in the manner described by "B. R.," why should he not also get into a tub and lift that and himself up by the handles? "B. R." has "demonstrated" his process on the small scale. It is unwise to experiment always on the scale of 12in. to the foot; but if "B. R." had adopted that scale on this occasion, he would have been a little wiser than his letter on p. 195 "demonstrates."

Nun. Dor.

STEERING OCEAN STEAMERS.

[26505.]—I observed the letter on p. 67, by Mr. James McCash Govan, "not by the merest chance," but directly it appeared, though I have not had time to reply before. He is, no doubt, acquainted with the reports made to the British Association on the steering of steamers, and with the experiments made by Prof. Osborne Reynolds and the committee; if not, he might refer to them or to your back volumes. In Vol. XXVII. p. 649, there is an abstract of a report, in which it is stated that a screw-steamer, by using the rudder, should be able to turn herself through a *quadrant*

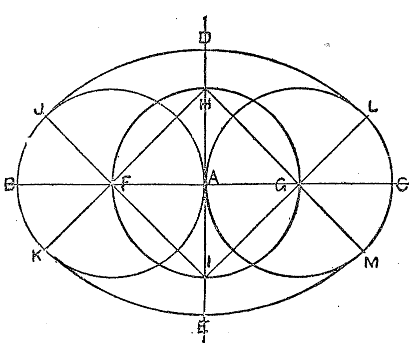
without having advanced five lengths in her original direction. Probably nine out of ten masters would, when a collision is imminent, order the reversal of the engines, in spite of the reports presented to the British Association, in which the folly of that action was denounced, because it had been demonstrated by experiments. I am not aware that I ever said "counsel" had anything to do with the "finding" of the inquiry; but if counsel are employed to represent the conduct of officers and owners as favourably as possible, other counsel ought to be employed who are capable of putting the expert evidence through cross-examination. Many a statement is made before boards of inquiry which would be turned inside out if "counsel" were able to see its absurdity.

Nun. Dor.

EASY METHOD OF MAKING AN ELLIPSE.

[26506.]—THE accompanying easy method of producing an ellipse may be of interest to your readers. So far as I am aware, it is original and new.

At the point A let two straight lines, B C and D E, cross each other at right angles. From



the centre A, draw a circle F G H I; and from F and G draw two other circles of the same circumference as F G H I.

From the points H and I draw four straight lines through the points F and G to the points J K L and M. Then from the centres H and I draw the arcs J D L and K E M.

An ellipse of any size may be produced by making the diameter of the first circle half the length of the desired ellipse.

Dudley. **H. C. Crew.**

THE "15-COACH TEST"—MIDLAND LOCOMOTIVE WORK AND DOUBLE-ENGINE RUNNING.

[26507.]—I OBSERVE that "P." (letter 26091, page 528) states that the "15-coach test," as applied to express engines, "consists in an engine drawing 15 coaches (180 tons) at 60 miles an hour on the level." I have pointed out, in a recent letter, that this is a complete misapprehension. The standard weight per coach adopted for the purpose of this test is 10 tons, not 12, and therefore of the test train 150 tons, not 180. A train of 180 tons weight represents 18 coaches, according to the rule laid down. This has been explained in your columns over and over again by our valued fellow-correspondent Mr. C. E. Stretton, so that I am surprised to find any of your readers ignorant of the rule. The standard trains used in the celebrated Newark brake trials ranged from 149 to 151 tons in weight, and were kept as nearly to the prescribed 150 tons as the different "makes" of rolling-stock permitted. The standard test of an express engine is to haul 150 tons (exclusive of its own weight, and that of its tender) at the rate of a mile a minute on the level. I have known an old engine with 6ft. drivers, and cylinders only 15in. by 22in., take 15 coaches at 60 miles an hour on the level. But the coaches only weighed six or seven tons each. On the other hand, I question whether the most powerful modern locomotive could take 15 Pullmans or Midland 12-wheeled bogies at anything like 50 miles an hour on the level. The term "coach" in such a comparison is misleading, for it may mean a vehicle of 5 tons or another of 24. It would be much better to deal with absolute known weights. Still, as a rough-and-ready mode of reckoning engine work, the present practice of estimating 10 tons to a coach is sufficiently near so long as it is clearly understood that these "coaches" are to represent 10 tons each.

Another of "P.'s" statements which needs correction relates to the working of the Midland trains. He says:—(1) "All the Midland Manchester trains average 11 coaches from St. Pancras. and even this light weight is divided over the Peak," and (2) "It is very rare to see a Midland express with over 14 coaches and one engine only; once get over 14, and a pilot goes on."

I am at a loss to understand upon what data these sweeping assertions are based; but, from my own long-continued personal observations during last year and the year before, I am able to give them a direct contradiction. I have known the M.R. Manchester and Liverpool expresses over and over again taken over the Peak undivided, and with one engine, although consisting of 12, 13, and 14 coaches, and in excellent time, too. I have myself timed Nos. 1315, 1563, and 1564 on several occasions with such loads, and in all weathers, time being admirably kept. As to (2) the assertion that a pilot is always taken with 14 coaches, it is ridiculously inaccurate. During all my lengthened observations of the M.R. working at St. Pancras station, I did not once see a train either arrive or depart with two engines to 14 carriages or even to 15. I once knew the day Scotch express leave with two of the 800 class on, and 16 coaches; but in that case the pilot left at Wellingborough, the run thither being done considerably under time. And I once came in with the Scotch express of 17, and two engines; but that run was accomplished in 16 minutes under time from Leicester. I only once saw a pilot on a Midland express of 14 coaches, and that was on the midday Manchester express which left St. Pancras with only one engine (No. 1489), and ran from Kentish Town to Bedford in 59 minutes, but took a pilot (No. 108) thence to Leicester, the weather being unfavourable. The same engine, on the same train, another time, left St. Pancras with 15 on, ran from Kentish Town to Bedford in 58 minutes, and then took No. 824 as pilot to Leicester. That was the only instance of a second engine being used with 15, in my experience, on any part of the M.R.

On the other hand, No. 814 kept time with 19 from Normanton to Leicester, and No. 812 with 20 over the same distance; No. 1573 with 20 from Aisgill to Skipton, and No. 1309, with the same number, from Skipton to Normanton. No. 829 brought 16 from Leicester in 1 hour 59 min. to Kentish Town (stopping there by signal) in spite of slackening to 10 miles an hour at the foot of the Desborough, Irchester, and Ampthill banks, the two former by signal. The same engine took a train of like weight from Leicester to St. Pancras in exactly two hours. The Scotch express is referred to in all these cases, which were by no means exceptional. On one occasion the up Scotch express had two engines on, with 17 coaches, from Leicester to London, being a little late at the former station. But in that instance the distance was run in 1 hour 52 min., and there is not the slightest doubt that either of the engines used could have easily drawn that train, or even a longer one, within the 2 hours 8 min. allowed. All these are given from personal observation, and very careful timing.

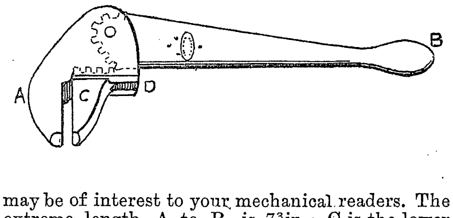
Evidently your correspondents must have seen "return pilots" going home after bringing in a heavy up-train, for most assuredly engines of the 800, 1472, 1562, and 1,667 classes can take 15 or 16 coaches, and keep time with the greatest ease.

Charles Rous-Marten.

Wellington, N.Z., Sept. 22.

SPANNERS.

[26508.]—TALKING of spanners (e.g. 26458), I wonder whether many of your readers know of an excellent French one, first introduced to my notice by a cycling friend, which I tried in vain to get in England, and at last obtained at the "Forge Vulcain" in Paris, after many fruitless attempts at other shops there. It is called "Clef Samuel," and possesses the great merit of tightening itself one way, and relaxing its hold when turned the other way, so that it adapts itself to any sized nut. It beats everything else in the spanner line which I have come across. I append a sketch of it, as it



may be of interest to your mechanical readers. The extreme length, A to B, is 7⅝in.; C is the lower jaw working up and down slide D, by means of ratchet connection, with the stand B inside (shown by dotted circles). It will take nuts from ⅛in. to 1in.

C. H. C.

OPERA AND FIELD-GLASSES, &c.—TO "O. V." AND MR. E. HOLMES.

[26509.]—"O. V." MUST not think that I have overlooked his query; stress of work has prevented me from writing before. There is considerable difference in the proportions adopted by different makers: some prefer a dumpy arrangement. I think there is nothing but greater portability to recommend that form. 5·5in. for the o.g.'s and 2in. for the eyepiece lenses are good proportions for the foci of opera-glasses of six-lens construction; with diameter of o.g.'s not to exceed 1⅝in. These give a power of 2·25, which is quite enough, to my mind. Anything greater only shows up rouge powder and other "properties" too much. Little, if any, difference is needed in the focus of the eye lenses for "field" or "marine." The increase of power necessarily being the effect of the o.g., which is proportionally increased in focal length and diameter until the limit is reached. Twenty-eight lines is the usual limit. In 10 and 12 lens forms the proportions of foci differ within certain limits. The highest I have seen that could be used comfortably have a proportion of 5 to 1. Some years ago I worked a large number of lenses for those compound glasses that were furnished with three sets of eye lenses marked "opera," "field," "marine." Of this form it could be said that the "opera" was too powerful, or the "field" and "marine" too weak. I need not tell our old friend that in this form of Galilean telescope we cannot let the eye travel out of the centre without getting prismaticity; to get the best effect, constant central vision is necessary. Although some advocate an increase of power up even to 10, I do not advise it, for however well the aberrations are corrected, the difficulty of keeping up this central vision is increased in proportion with the power. As to the 16-lens glasses: well, I have heard of five-wheeled coaches—I have never seen the latter; the former I have, and should say the fifth wheel and all lenses beyond 12 are equally useful. I am, however, too dull to discover where this usefulness comes in.

A statement made by Mr. E. Holmes, in his last-published letter, *re* the "English v. Foreign Microscope" controversy (wisely ended by our patient Editor), I must refute, as it affects my status in the eyes of the readers of the "E. M."

I beg to state to Mr. Holmes that I am *not* an "interested party," as an Englishman understands that phrase, seeing that I write independently, and have not a *shilling* of money invested in any firm whatever. When I have, if ever, I shall let Mr. H. and all "ours" know.

Prismatique.

EGYPTOLOGY, &c.

[26510.]—IF the early Hebrews seem, "Memnon" tells us, "to have been all Sadducees," will he tell us what to understand by the phrase being "gathered to his fathers," said of Abraham, Aaron, and Moses; or "gathered to his people," said of the same, and of Ishmael, Isaac, and Jacob? It is certain that the bodies of none of the three former were buried within hundreds of miles of any of their kindred. Abraham's immediate father had died in Mesopotamia; and earlier ancestors at Ur in Chaldea. Aaron and Moses were each ordered to ascend a desert mountain, to "be gathered to thy people"; and Moses was buried by no human hands, but by some landslip or avalanche; the Lord buried him, and "no man knoweth of his sepulchre." It was necessary to oppose all the false rubbish taught in Egypt about spirit life, and this could only be done by leaving all inevitable allusions thereto as vague as possible. The prohibition of dealing with witches, necromancers, or "mediums" (as they are now called), not only implied such dealings with the dead to be real (as "Ramases" says); but when Saul broke this law, the ghost of Samuel is declared to have come and prophesied, though not by the woman's agency, because unexpected by, and frightening her.

Even in Job, probably the oldest story, it is implied that he would, like David, rejoin his children. It is plainly declared that at last *everything* he had lost was doubled, but though the numbers of each kind of cattle are so, the numbers of sons and daughters are simply those of the dead ones exactly repeated. Jeroboam's queen was told that her young son should die *because* he was the only one of the family wherein some good was found? Very odd Sadduceeism. But, in fact, it takes long ages of corruption and sophistry in any nation to bring even their rulers to Sadduceeism, as that of Hezekiah, Julius Cæsar, or Byron. It was no more possible to a horde of simple proletaries, just delivered from two centuries of bondage, than was their being legislated for in a foreign language.

When "Memnon" asks for evidence that Moses wrote Coptic, it was enough to point to wherever he is said to have written anything. If writing for his people at all, it must have been in their sole possible language at the time. And to say their later language ought to retain Egyptian words, is equivalent to saying the last Disraeli (Beaconsfield) must have mixed Italian words in his English, because his grandfather had been born in Venice, or rather because his ancestry had four centuries ago.

What on earth can "Memnon" mean by the "ascription of the same story to Abram, Gen. xii.,

and to Isaac in xxvi.?" Is Gerar another name for Egypt, and is Abimelech the same as Pharaoh, and the Philistines as the Egyptians? Or was losing his wife, and being taken into the King's harem, the same as having it accidentally discovered that she was not his sister? and being expelled the country in disgrace the same as being declared "much mightier" than the king, and begged to make an alliance with him? Though Isaac and Jacob were, at some dates in the 400 years, rich in cattle and silver and gold, the prediction that they should all the time be landless "sojourners" in land that was not theirs, always remained true, and Jacob was invited into Egypt lest he "and his house come to poverty." It is never said of them, but only of Abraham, that God "had blessed him in all things." What is the difference between ordering Noah to have two of every animal, and afterwards ordering seven of *some* kinds? And would not any writer who held that God had not revealed a name as his to anyone before Moses, necessarily apply that name to the God of their fathers from the beginning? How otherwise was he to make it understood that two names were not those of two Gods? But such a string of worn-out quibbles, repeated parrot-like out of Voltaire, without even examining one, are not worth notice. Each of the six books after Genesis begins with the copulative conjunction "and" or "now," stamping the whole as one writer's single work. And as he left it, so it stands. There is no trace of any words interpolated, though doubtless of some dropping out, and the numeral dates being corrupted two ways, in the Jewish and Samaritan copies. Even were there no other witness, the absurdities thus produced in them, and self-consistency of the LXX. alone, could leave no doubt which of the three kept them genuine. But Josephus, agreeing with the latter, is an independent witness, and *on this one point* quite as weighty as any of them. He was one of the 24 chief-priests when Jerusalem fell (though not living there) and was allowed by the emperor to take and keep a choice Temple copy of his national scriptures, which he employed, of course, in writing his "antiquities." There is all the means possible to conceive, of telling which versions are the falsified ones.

If "Memnon" wants "one or two points" selected for his attack, I advise him to concentrate forces on the Deluge, its recency and universality. Let him open the late C. Darwin's first *Journal of Researches*, and explain the facts ending Chapter VIII. without the fall, about 50 centuries ago, of a fresh sea from the sky, and upon every part of this globe at once.

Nov. 15. **E. L. G.**

EGYPTOLOGY.

[26511.]—A PAGE of the MS. of my letter must have slipped out, as my quotation from Genesis and other matter have not been completed. They may not have been of much importance; but I should like to complete the quotation.

After the word "transferred," at the end of letter, add "to signify a century."

"Memnon" (26477) in replying to "E. L. G.," raises a few other objections, which I should like to notice.

The fact of the name Jehovah being put into the mouth of the patriarch before it was revealed is cited. The answer is easy enough. All nations have had a general and personal name for the Deity or their gods. As it is claimed that Moses wrote the patriarch's words, it was natural for him to use the personal name revealed to him.

"Memnon" may find that the Jehovistic and Elohistic theory has been squashed by Quarry's exact list of names and passages. The "Speaker's Commentary," a work by very decently-educated men, gives the list, I think, and upholds the authenticity of the Pentateuch.

There is too much testimony in all nations regarding the Deluge to allow unbiased minds to doubt of its occurrence. The language of the Bible regarding it is here, as elsewhere, the language of common life. It is the testimony of human witnesses as to what they saw, heard, or was revealed to them, put into their own manner of speech, and this, while exhibiting their own imperfections, does not impair the testimony.

Miracles being admitted, and even Prof. Huxley says that it is only a matter of testimony, then to slow the rotation of the earth and preserve its form, so that the sun hasted not to go down for a whole day, appears to me to be as simple as any miracle in the Bible.

Nov. 12. **Ramases.**

[26512.]—WILL "Memnon" pardon me for interposing for a moment in the controversy with respect to one point—the Deluge? He remarks most truly that the "Bible says it covered the whole earth." But what was the "whole earth" then? In judging of the Bible, it is only fair to take what it does say. Gen. i. 10 declares that the waters were gathered together unto *one* place and the dry land appeared. Consequently, the Bible at the Creation and at the time of the Flood is responsible only for *one* dry land and *one* ocean. According to the Bible the land was watered by evaporation, as no rain fell till the Flood. What was the extent of the dry land we cannot determine; but as Greswell says: "Nor were such a problem as this, By what amount of the surface of water constantly exposed to evaporation, greater than at present, might the same physical needs of the animal and vegetable kingdoms of nature be supplied even at present, independently of rain? to be proposed to the chemist or geologist, would it be difficult for him to solve in a general way." The Bible up to the period of the Flood is no way responsible for any land south of the shores of the Mediterranean. Greswell says, again: "This peculiarity of the constitution of the world before the Flood is the true explanation of the mistake and apprehension of that of the post-Diluvian world, into which the oldest geographers among the Greeks and the other nations of antiquity appear to have fallen in common: that of assuming that the earth of their own world was surrounded by an ocean on all sides too. This fact was true of the earth before the Flood, and having been handed down by tradition into the post-Diluvian world, it naturally led to the mistake in question. Nothing was more likely to be assumed at first than that the post-Diluvian world, in its external constitution, was nothing different from the ante-Diluvian."

I hope that these quotations may throw some light upon an apparent—and I am sure only an *apparent*—difficulty as to the Mosaic history. A great deal more might be added, which consideration for your space forbids; but if "Memnon" is, as I believe he is, only anxious for the truth and a fair criticism upon Moses, I venture to recommend to him and your readers Greswell's "Three Witnesses," London, 1862. **Ponto.**

[26513.]—"RAMASES" scarcely proves his case by asserting (26476) that he gave as evidence the early Jewish historians, as, for instance, Joshua; because they are quite as doubtful as the Pentateuch. As for Joshua quoting Deuteronomy, that is rather against the age of the former, as the latter is supposed to be the book found in the Temple in the time of Joshua by Hilkiah—who, it is likely, wrote it and placed it there. He *may* have had traditions, or old annals, or writings to work up; but the late character of the book has been fully shown by De Wette, and also, I understand, by "Ramases'" favourite, Gesenius. I only briefly refer to this at present, as I prefer to urge the Egyptian point. I do *not rely* on Manetho. I rely on the list of great Egyptologists whose names and opinions I gave, and consider that "Ramases" ought to look with respect on such men as Bunsen, Lepsius, Mariette, Brugsch, &c., who carefully studied all known historical records bearing on the subject, and all ancient existing monuments, &c., found in Egypt. All these great men place the beginning of the Egyptian monarchy (not the beginning of the civilisation of Egypt) *long before the time Genesis ascribes to the universal flood*. That is the point I urged on "Ramases,"—not the value to attach to a late historian like Manetho, of whose work no undoubted or perfect copy remains, only quotations. M. Sayce says: "It is plain, therefore, that Manetho's list has come down to us in a very corrupt condition, and that the numbers contained in it must be received with extreme caution. Moreover, the Christian writers who have handed them down were intent on reconciling the chronology of the Egyptian historians with that of the Old Testament, and were consequently likely to curtail it as much as possible." "His statements, notwithstanding the imperfect state in which they have reached us, are in the main correct." Mr. Sayce is Deputy Professor of Comparative Philology at Oxford, and is a man of weight and great information. He considers Mariette's date for Menes to be most nearly right, and it is 5004 B.C., or nearly 3,000 years before the Flood. He says: "We shall provisionally adopt the dates of Mariette, whose long-continued excavations in Egypt have given him an exceptional authority to speak upon the matter; but those who have sailed up the Nile and observed the various phases through which Egyptian art has passed, will be inclined to think he has rather fallen short of the mark than gone beyond it." But Genesis says the universal Deluge took place only 2288 B.C. (or, according to Usher, in 2348), and that for a time Noah's immediate descendants (the only living people) lived somewhere in the far East, and only dispersed in Peleg's time. Does "Ramases" really accept these dates? Can he bring himself to squeeze up the development of the great, the peculiar, the intricate and definite civilisation of ancient Egypt into a few miserable years to suit Genesis? Can he suppose it sprang into full life from such people as Noah's sons and daughters? To me it is absolutely impossible to do so, nor can I imagine anyone free from overmastering theological necessity who could do so. If "Ramases" really doubts the great antiquity of Egypt, he should study the remains of Ancient Egyptian art, which he will find highly developed, and quite different in all respects from anything Babylonish or Hindoo. The great temples at Thebes, &c., are of the time of Moses or thereabouts, but are unmistakably modern compared to the old Memphite pyramids, tombs, and figures. The style of temple of the 18th and 19th dynasties is quite different from that of the older period, which can be ascertained from the fronts of old tombs, from the Sarcophagus of Mycerinus (a model of an old temple), and from the remains of the temple near the Sphinx. These, though so old, are the stone developments of a wooden style, every detail representing carpenters' work, the date of the invention of which is absolutely unattainable, being lost in the mists of extreme antiquity.

Then the Pyramids themselves are of immense age. Ferguson, in his celebrated "History of Architecture," says of them: "If one point in Egyptian history is proved with more certainty than another, it is that the Great Pyramids of Ghizeh were erected by kings of the 4th dynasty; and it seems impossible to find room for the now ascertained facts of Egyptian chronology, unless we place their erection at least 3,000 years before the Christian Era," and, speaking of their structural qualities, he says, "Nothing more perfect, mechanically, has ever been erected since that time; and we ask ourselves in vain how long it must have taken before men acquired such experience and such skill, or were so perfectly organised as to contemplate and complete such undertakings." How long did it take to develop the hieroglyphics, and the Osirian system they were used to express? No better statue can be found of its kind than that of Chephron, the erector of the second pyramid; it is of the hardest stone, is deeply imbued with the peculiar spirit of the style, and is of splendid workmanship. How long can "Ramases" suppose it took to develop such an art? It is the oldest movable stone statue in the world; but is probably not nearly as old as the Sphinx, which that particular king restored; yet the Sphinx is also as peculiar as anything in Egypt. Then the splendid tomb of Ti is of the 5th dynasty, and is as perfect in sculpture and painting as the best work of any later period. Will "Ramases" say that some immediate descendant of Shem, Ham, or Japhet designed and carried it out? One of my principal points was the gross improbability of Moses only allowing 1,000 years from the late period of Rameses II. or Maneptha in the 19th dynasty for the rise of the whole civilisation from Noah and the contents of his Ark.

If Moses was learned in the learning of Egypt, it seems wholly impossible he could do so, and if he were not, how can we rely on Exodus, which says he was? That is the question I want "Ramases" to answer. "Ramases" admits that Menes was known in Rameses II.'s time, so that Moses ought to have known what was inscribed on public monuments.

"Ramases'" remark about Deut. xviii. remains to me of very doubtful value, and if Moses, or the writer or writers of the Pentateuch, believed in immortality, it is a great pity they did not say so, and so spare apologists the difficult task of trying to prove that they did by their condemnation in one case of "necromancers." Does "Ramases" forget Bishop Warburton's well-known book on "The Divine Legation of Moses Demonstrated on the Principles of a Religious Deist, from the *Omission* of the Doctrine of a Future State of Rewards and Punishments in the Jewish Dispensation"? I will leave the point with your readers, reminding them that the particular doctrine omitted was the central point of Egyptian doctrine, and that "Ramases" supposes that Moses believed in it.

That the death of Moses should be recorded is most natural, though not by himself; and I fail to note any difference in style between the part in which that notification is made and the rest. "Ramases" can only assert that there is, but cannot prove it.

That kings were promised to come from Jacob's loins is only another proof of the lateness of the book; as even in the time of Samuel kings were objected to as bad and irreligious by him in his character of prophet, and kingship could not be supposed to be a reward of virtue till kings had been accepted by and were familiar to all classes of the Jews.

As to Gesenius, if a generation means 100 years (which I do not admit), then the Jews were about 400 years in Egypt (four generations). Gesenius approved of Van Bohlen's work on Genesis, and Van Bohlen's views are generally the same as mine.

I fully admit that Genesis must be considered to be a valuable historical document; but do not look on the stories of Abraham, Isaac, Jacob, and Joseph or Moses to be real history. *The genealogies* are probably compiled from old short records, but refer more likely to nations than single persons.

Memnon.

EGYPTOLOGY.

[26514.]—"MEMNON," in his remarks about Samuel being the author of the Pentateuch, proves too much, because the office and position which Samuel held (high priest and judge), as also the reformation he accomplished, would have been an utter impossibility without the previous existence of the Pentateuch and its being believed in by the Israelites. That Samuel was the arranger of the Pentateuch along with the book of Joshua, and that he wrote Judges, I don't suppose there is any reason to doubt; but editing or arranging is one thing, being author or forger is another and totally different, and splendid as were the abilities of Samuel, it's just rather too much to ask us to believe in such a stupendous forgery, or that the Israelites were such fools as to accept it, more especially when we take into consideration the miserable state of affairs disclosed in the Book of Judges.

Also, "E. L. G." fails in his explanation of Joshua's miracle. Those Bible miracles may be accepted or rejected (it's entirely a matter of private judgment); but to try to explain them or thin them down is satisfactory to no one, because they have all this in common: that they just supply the exact amount of help for the work to be done and then cease. They are also, *without exception*, in strict harmony with the narrative, so that if the miracle is explained away, then the narrative must go with it. And "E. L. G." will soon see the necessity of keeping *strictly* to the Scripture statement, if he will take a scale map of Palestine and a pair of compasses (and taking the narrative strictly as a military movement), measure the ground covered along with the work done: it will then appear that the main point has always been overlooked—viz., that unless the two miracles (sun, moon, and hailstorm) had taken place, the work done could not have been accomplished. Joshua's march up the steep pass from Gilgal to Gibeon was about 20 miles, the fighting up the rise to Beth-horon was over six miles of ground, and Joshua having gained the ridge, from which he had a view of the valley of Ajalon, stretching away for 25 miles to Jarmuth and the plain beyond, his military experience told him that unless he could head, turn, and slay the Amorites before they escaped to their cities, his movement would be a comparative failure; at the same time he must have seen that the night would come on before the work could be done, that an extension of the daylight was required;—hence his request, and the miracle as an answer. The amount of ground covered in a straight line from Gilgal to Jarmuth is just over 50 miles, and, adding the return back to Makkedah, made up a pretty stiff bit of work; so that if the miracle is explained away, then the narrative must go with it. **Dens.**

AN EXTRA-MUNDANE VISITOR.

[26515.]—ON Tuesday, Nov. 2, at eight minutes past eight, I saw a magnificent meteor. It appeared as a tiny star almost at the zenith, and its rapid motion first attracting my attention, descending as it did with a luminous train, apparently 30 yards in length, of a bluish-white light, resembling the electric-arc in purity of colour.

The nucleus appeared as large as a man's head, and could easily be distinguished by its increased brilliancy: as it fell to earth the extremity of the train was broken up into sparks, which reminded one of the sparks produced by friction against a grinder's wheel by the conversion of motion into heat. Its path of flight was inclined at an angle of about 15°, and, roughly speaking, it descended almost vertically upon the town. I went in search of this fragment of "cosmical matter," but all to no purpose. Several persons saw it fall, and all say, "Why, it fell within a stone's throw of us"; while another person, who was some miles from Newport on his bicycle, said, "It dropped about two or three fields off." So what is one to do when virtual images present themselves?

I estimate its transit from the minute point of light at the zenith to its impact with the earth as seven or eight seconds at the most.

No hissing noise accompanied this meteor by the rapid displacement of air, but a slight odour of sulphurous acid I could distinctly smell just after it had fallen. This is not altogether unknown, as meteors, in some instances, have shown as much as 7 per cent. of iron pyrites upon analysis.

Newport, Mon. **A. Treyer Evans.**

SUGAR ANALYSIS.

[26516.]—WHILE Mr. Allen is favouring us with help on the subject of grape sugar, I would ask him to give us further information about the "other substances" to which he refers as reducing the alkaline solutions of copper tartrate, and which, therefore, sometimes introduce fallacies. This point is one on which Sutton's "Volumetric Analysis" is silent, and it is one of considerable importance in the arts.

In cases of diabetes there are sometimes reactions under Fehling's test which are but very imperfectly explained in textbooks. Sometimes, instead of the full red precipitate of copper suboxide, in possible diabetic cases one gets a muddy yellow discolouration, which will neither yield a clear filtrate nor a definite subsidence. There are also other doubtful changes. What is the significance of these?

Would Mr. Allen favour us with his opinion on the new ammoniated copper test (vide *Lancet*, March 1, 1884) and the fallacies to which it is liable? For the ammoniated copper test, 4·148 grammes of crystallised sulphate of copper are prescribed to the litre, while Sutton prescribes, for Fehling's solution, 34·64 grammes; yet in the standard Fehling 10 cubic centimètres are said to equal 50 milligrammes of grape sugar, while in the ammoniated copper solution 10 cubic centimètres are said to equal 5 milligrammes of grape sugar. Hence in the one solution 4·148 grammes of copper sulphate perform the same duty as 3·464 grammes in the other. How is this?

In making up these standard solutions, the precise quantity of copper oxide contained in each cubic centimètre is, I believe, the point on which their standard depends. But, in the caustic alkali, may we use soda or potash indifferently for all purposes of sugar testing? And, in the alkaline tartrate, may we also use the Rochelle salt, the disodic tartrate, or the dipotassic tartrate, indifferently? Does it, in fact, make any difference whether we use an alkaline sodic tartrate of copper, an alkaline potassic tartrate, or an alkaline sodio-potassic tartrate? Then, again, need the caustic alkali or the alkaline tartrate be adjusted with precision, in order to make the test work accurately?

What are the chemical changes induced in the grape sugar and in the tartaric acid under the action of the alkaline copper tartrate tests?

Mr. Allen's special knowledge on these subjects is such that we shall be much obliged if he will kindly supplement our ordinary textbooks with his guidance on these practical points.

M. O. H.

CARBONATE OF MANGANESE.

[26517.]—THE ore mentioned in your last issue by Mr. Blackwell (26487) as sold by him from this district for many years was not carbonate of manganese, but was taken from the oxidised "outcrop" of the bed which does not show any carbonate on analysis, having been turned into an oxide by the action of the elements.

The bed can be traced over a large tract of country, and has been extensively worked as far back as fifty years ago, the produce being sold for chemical purposes; but the people who then worked it only stripped off the oxidised outcrop, as the pink carbonate could not then be turned to any industrial use. This method of procedure was also followed at the mine from which Mr. Blackwell bought his ore, the pink carbonate being left behind as useless.

We must claim to be the first discoverers of this pink substance being carbonate of manganese, and utilising it for the purpose of spiegeleisen-making at Mostyn. **Henry S. Lancaster.**

The Dyffryn Mining Company, Llanbedr, R.S.O., Merionethshire, Nov. 15.

LAUNCH ENGINES.

[26518.]—IN reference to Mr. Taylor's letter, No. 26402, page 173, which I have been unable to reply to earlier, my opinion on the failure of the engines having two h.p. cylinders and one l.p. was chiefly due to excessive back pressure on the h.p. pistons. If we assume that the pressure to be maintained in the receiver must be 20lb., the engine under notice had two 7in. cylinders and one 12in. diameter, steam pressure 70lb., and the rate of expansion was 5. Effective mean pressure in h.p. cylinders was 58lb., with of course a back pressure of 20lb. on each piston, from which it will naturally appear that from the extra back pressure and the power absorbed in the l.p. cylinder that there is a decided loss. In your case, by placing the two h.p. on top of the low there would be no gain of power, but you would have more economy in fuel.

I hear that one or two yacht builders are fitting the triple-expansion engine in the larger size yachts. I have before me an account where a yacht, 113ft. by 20ft. by 13ft., having cylinders 9½in., 15in. and 24½in. in diameter respectively; stroke of piston, 18in.; steam pressure, 150lb., she obtained a speed of 8½ knots per hour in unfavourable weather.

Engineering, Manchester.

"F. A. M.'s" LATHE.

[26519.]—WOULD not the upper slides be better if so made that the upper member was borne upon a shelf projecting from each side of the lower, instead of resting upon the surface of the latter, as is shown, for example, in the illustration of Taylor's slide-rest which appeared a short time ago? I think I recollect "J. K. P." in an old letter speaking well of this construction. The lower short slide might with advantage have brackets to support its overhang at each end.

The "vice screw" alluded to by "Vulcan," p. 156, is, I presume, the tailscrew of tool-holder. It will be found an advantage to turn this screw upside down, as I have in my own lathe. The lever then is quite out of the way, for it slips between the plates; the pressure is borne by the broad head of screw instead of the narrow point, and the tail of upper plate may, if thought advisable, be made thicker to withstand wear, without practically taking more room than at present. There should be a stud on the head, taking into groove on the lower plate, so as to keep both parallel.

I should like to see fixed levers or other devices for dispensing with the use of spanners more freely employed. The saving of time, especially on an "odd job" lathe, would be considerable, to say nothing of the bother of perpetually hunting for the appropriate wrench, the chance of using an ill-fitting one, and perhaps damage done by accidental blows. The change-wheel gear, for example, affords several opportunities in this direction, and I recollect seeing a suggestion that spring snaps might be used with advantage, instead of nuts, on the change-wheel studs, since there is not much strain to be resisted. It would be an advantage, too, if the backgear wheel could be clamped to the pulley without the use of a spanner, especially if, as in my lathe, there is a division circle on the rim of the wheel, which is liable to damage should the spanner slip.

The handle that clamps the traverse slide has scarcely room to turn, especially after wear. May I suggest an eccentric fastening to grip by pressing down the handle? If, however, a screw bolt be preferable, it might have a large capstan head or be prolonged so that the handle might be low enough to clear the two brackets.

I would suggest also a taper set-pin to each of the circular movements, such as is, I believe, generally fitted to an eccentric chuck, as a readier and more accurate mode of setting them to "square," than the use of graduations.

The slide-rest handles are, I think, most convenient in the form of a good-sized, milled-edged disc, with a *small* handle, or rather, knob, so as not to get in the way when turning the disc. I remember a letter of "D. H. G.'s" on this point well worth reading, as need hardly be said. A much more regular feed can be given with a disc than with a crank, and the handles are better balanced. They will be more readily put on if about ¼in. of either the square hole or square peg be bored or turned circular, since it is quicker to put a round peg into a square hole (or vice-versâ) than a square peg into a square hole.

As to covering the sliding collar, how would a strip of thin, hard brass, rolled up like a tubular shaving, answer? the point being that it would expand and contract with the traverse of the mandrel, and therefore might be always in place, whilst a removable shield, if left in situ by accident, would be crushed during the traverse, or spoil the half-nut.

I am afraid these comments are but trivial, but "F. A. M.'s" well thought out design scarcely leaves room for more vital criticism. **Faber.**

The Golden Chub.—In the neighbourhood of Liverpool a successful attempt has been made to acclimatise the "Golden Orfe," a beautiful variety of chub. It comes from Bavaria, and has proved a hardy, healthy fish. It rises to the fly in enclosed waters, so that the fly-fishers may find sport in other places than running rivers. Round Liverpool it is impossible to enjoy any good fly-fishing, owing to the lack of trout streams, but this "orfe" is likely to supply the want. Ornamental fish, such as the goldfish, will not breed in our climate, or if ever they do the offspring is almost black; but with the orfe it is different. They breed freely, and the offspring retains the beautiful golden colour of the parent. It attains the length of 10in. or 12in., but has been known to reach nearly double that size, and weight about 6lb. For an aquarium it is a splendid fish, being almost as beautiful, and far more hardy, than the goldfish. They generally bear the trace of a dark-skinned ancestry in a few blotches of a brownish colour; but their good qualities more than atone for this. Some ponds near Liverpool have been stocked with them, and the result, so far, have been very satisfactory.—*Liverpool Mercury.*

THE Severn Tunnel, which has been opened since September 1st, for goods traffic, will shortly be opened for conveyance of passengers, which will add to the convenience of the travelling public, especially between the West of England and South Wales. The Great Western Railway Company have adopted Mr. C. E. Spagnoletti's new system of electric locking for working the traffic through this tunnel.

REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

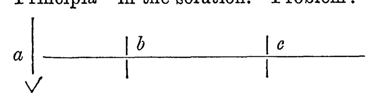
[60137.]—**Marking Ink.**—It is not quite clear what sort of ink "L." requires. That described on p. 562, last vol., is intended to be liquid, becoming indelible only after exposure to light. I do not believe it is really indelible; but it is the best I know, and I gave it for what it is worth. It seems to me that some of your querists ask for recipes which would be commercially valuable—if they existed. Now, I should like to say, once for all, that, while I am quite willing to dispense my small modicum of knowledge through your generous pages, I have no notion of "inventing" for the benefit of others. If I knew of a preparation which would answer as an indelible marking or stamping ink without the use of salts of silver, I think I should just expend a little more than a sovereign on some pieces of paper which would have my name written upon them, and be deposited in due course at a certain place in Southampton Buildings.—SAML. RAY.

[60192.]—**Annuity and Estate.**—In reply to these queries, the value of an annuity of £115, with 32 years to run, may be found by multiplying the value (115) by the number of years' purchase or value of £1 per annum at 5 per cent.—thus: 115 × 15·80 = 181,700 = £1,817. The same rule applies to the freehold estate thus:—Annual value, £65 × 20, the number of years' purchase at 5 per cent. = £1,300. The number of years' purchase at 6, 7, and 8 per cent. respectively would be 14·08, 12·65, and 11·43.—WM. P. MILLER.

[60216.]—**Mineral Waters.**—Dr. Allinson, upon visiting the celebrated (for 200 years at least) mineral springs of South Wales, situated on or near the banks of the river Wye, at Builth and Llandrindod, would, after hearing the oral traditionary lore about the wonderful cures effected by the minerals contained in these springs, soon alter his mind. He admits that cures take place, as at Malvern, where the water filtered through granite is chemically pure; but it so happens that cases incurable during a long sojourn at Malvern have become cured permanently in a few weeks at Llandrindod, notably hard tumours, scrofula, syphiloids, chronic abscesses, &c.—this, too, at a period (previous to the discovery of iodine therein) when medical men of standing declared that there was no element in these said springs which could account for these particular diseases getting well. The mineral springs of South Wales are of three kinds—i.e., saline or purgative, sulphurous, and ferruginous. Strange to say, these three are generally near to each other. Visitors seem to rely on the saline, the sulphurous being taken in the proportion of a wineglass to ten tumblers of the former, while special caution is always observed in taking the ferruginous water, owing to the adverse symptoms always found to result from large, frequent, or long-continued doses. Yet, used in doses of a tablespoonful three or four times a day, astonishingly beneficial action often soon happens and remains. In the steel rolling mills, where I am employed, many of my fellow-workmen experience symptoms of disordered health through inhaling iron oxide dust, which is so fine that it floats in the air we must of necessity breathe, with every vibration of the machinery. These symptoms seem to be identical with those against which visitors to the South Wales mineral waters are specially cautioned. At first, our fresh hands actually experience every appearance of improved health, better appetite, greater bodily strength, and higher spirits; but the opposite soon follows, and remains —so long as the men remain in the works. We have heard much about the two opposite actions of drugs or medicines, or poisons, and I write this hoping to hear still more, especially as to how to avoid the disordered digestion which long-continued inhaling of this iron oxide most surely causes, the actual daily dose of which, absorbed by the delicate moist surface of the lungs, reaching the organs of digestion through the circulation of the blood, cannot amount to many grains. In order to anticipate misconception on Dr. Allinson's part, we experience no local irritation to the lung surface itself—only those symptoms known to be caused by iron—when taken into the stomach in large or long-continued small doses.—REGULUS Swansea.

[60334.]—**Falling Bodies.**—I did not say I preferred "Vulcan's" reply. I did not know that "Dubliniensis" professed to give mathematically accurate replies. I beg his pardon, if it is his due. "Angulus" will see, I think, if he supposes the earth cut in halves, and the two halves separated, that when they were allowed to come together again, there would be pressure over the whole of the dividing plane, and, consequently, at the centre as much at least (more than) as at the sides.—M., York.

[60334.]—**Falling Bodies.**—I thank "Dubliniensis" for the correction of his proposition and for his references, though my challenge was not made with the intention of producing the former. My opinion is "acknowledgedly uninformed" to some extent; but on some points, and those the most important connected with orbital motion, I consider myself peculiarly competent to speak. I have not access to W. and T.'s "Dynamics"; but I now believe "Dubliniensis's" answer is correct physically. But mathematicians seem to differ, and it is interesting at times to discover how far. 10 water does not seem to me extreme density: platinum is 23. I do not think pressure (attraction) of gravity "slight" at earth's centre, but *nil*. To get 11,000 odd tons per sq. in. as total pressure at centre of earth, it is not only necessary to consider it homogeneous, but fluid also; or the vitreous crust must rest on a fluid below. I do not attach much weight to my own opinion, but I doubt the interior fluidity. Those who are very sure ought to be very right; so, will "Dubliniensis," or other, give a solution of the following problem in dynamics? I venture to differ from the "Principia" in the solution. Problem:—



c = centre of force, force varying inversely as the square of distance.
a = point of projection of b at infinitesimal velocity, at right angles to a, b, c, or axis major.
$a\,b$ = distance body falls in unit time, = $\frac{1}{9}$ a, b, c.
$a\,c$ = unit of distance, or $a\,b$ may be taken.

To find path, or other end of major axis, and time of falling to centre c in units $a\,b$.—VULCAN.

[60352.]—**Fire-Engine.**—Bore of cylinder, 7in.; stroke, 6in.; bore of pump, $7\frac{3}{8}$in.; ram, $5\frac{1}{4}$in.; length of air-vessel to delivery, 2ft. 11in.; diam., $11\frac{1}{2}$in.; diam. of flywheel, 2ft. 1in.; suction inlet, $3\frac{1}{2}$in.; delivery outlet, 2in. full; boiler: taper from bottom to centre, $7\frac{1}{4}$in.; diam. of bottom and centre, 1ft. $8\frac{1}{2}$in.; outer shell, 2ft. $3\frac{3}{4}$in. at bottom; length from bottom to top (outside), 4ft. $0\frac{5}{8}$in.; No. of tubes, 85; size, $\frac{7}{8}$ outside.—SAM KOE.

[60455.]—**Chemical.**—I must leave this query to the "inventors." I confess I do not see how it is possible for a dry pencil to make a raised mark on paper.—NUN. DOR.

[60506.]—**L. T. and S. E. Side Tank Engines.**—I think "Scales" is wrong in stating the weight of these engines at about 40 to 42 tons. If he will refer to page 319 of Volume XXXVII. he will find the weight given there as 56 tons 1cwt. 3qrs.—B.

[60523.]—**The Daniell Cell for Electric Lighting by Glow Lamps.**—As lamp makers, we really must protest against the remarks of Mr. Striffler and the advice given by him on p. 240 (reply 26479), as such advice is calculated to do harm to the advance of battery lighting. Mr. Striffler advises as an "economical means of lighting" for lamps to be overrun the marked voltage —for instance a lamp made for 5c.p. to 8c.p. Unless our readers have more money than they can do with, we should strongly advise them not to follow Mr. Striffler's plan, as no lamp, however well made, is expected to, nor can the filament bear such a pressure strain for long without eruption. It is therefore most disastrous and suicidal to recommend such a practice for general use. Fancy any electrical engineer of scientific experience running a 50 volt lamp of 16c.p. up to a brightness of 26 candles at a constant pressure of 75 to 80 volts E.M.F.! We fancy if Mr. Striffler tried the experiment, that after about 20 minutes' enjoyment of a good light he would find himself in the dark, in company with a lot of black glass globes with strangled filaments of no value. One can therefore well understand the reason why Mr. Striffler's 6 volt lamps of only 5 ohms resistance explode when fed from a modified Daniell cell of 15 elements as described, especially when such a battery would be far more suitable to feed eight of our 18 volt Standard lamps of 10c.p. run in parallel, or, probably better still, fourteen 5c.p. lamps specially made to run two in series, but coupled as one lamp to the branch wires leading from the main circuit. Lamps of low resistance, it is quite true, are well known to take a little more current than lamps of high E.M.F.; but this does not matter, as it requires fully 40 per cent. more outlay for plant to obtain the same lighting effect, and fortunately the public, as they become more enlightened, begin to realise the advantages of using a glow lamp of low resistance for small installations over a lamp of the Edison type of h.r., and invented by him especially for central station lighting, for which they are admirably adapted; but there is no disputing the fact that a glow lamp of low resistance is far the best and more economical for small domestic electric light installations where only a few lamps are required and not overrun the normal candle-power described by the makers. As Mr. Striffler has written in a somewhat ambiguous manner respecting our battery lamps, in reply we simply challenge and defy him to procure from any other maker a 6 volt 5c.p. lamp of 4·5 ohms resistance of any type of lamp, from Edison downwards, with an efficiency of 3 watts per c.p. Whether such results are "wonderful" or not, we are quite content to leave the answer to our scientific electricians to judge for themselves. We have no wish to "crack up" our lamps or unduly praise them; but knowing that we have gained a reputation amongst the trade as makers of the best and cheapest lamps in the market for battery use, which are also free from infringement (just now a very important feature), we have a right to protect them. At the same time, if Mr. Striffler is content in paying 5s. for an article not so good as that sold by us at 3s., he is at liberty so to do; but there are at present in England and abroad over 10,000 users who are nightly burning our lamps who, we feel sure, will not take the same view as that of our worthy contributor, who, by the bye, even himself admits that they are "cheap and good," and coming as it does from a prejudiced consumer scores another point in favour of the so-called "Wonderful," as advertised in Sale Column by—SHIPPEY BROTHERS.

[60564.]—**Timber Truss.**—Hurst's "Tredgold" or Tarn's "Tredgold" will give the information required. The first is published by Spon, the other by Lockwood.—NOMEN.

[60565.]—**Mastic Varnish for Oil Paintings.**—There is no secret in the making of the varnish; but it must be applied in a warm, rather dry atmosphere. Ten ounces of picked mastic to a pint of the best turpentine is about right. Set on a sand-bath until dissolved, then strain through a fine sieve. Thin with best turpentine if too thick. N.B.—Mastic varnish improves with age, and to assist in the solution of the gum it is advisable to pound it small, and mix it with powdered glass or coarse silver sand, which may be made warm with advantage before mixing.—SAML. RAY.

[60567.]—**Broken Backbone of Bicycle.**—If the querist is going to ride the machine himself, I would advise him to have the backbone properly repaired, or preferably replaced by a new one.—ESSAR.

[60568.]—**Bleaching Greasy Silk.**—I do not think spirits of salts is used for bleaching silk, except in the form of nitro-muriatic acid, or aqua-regia. Mix five parts of muriatic acid with one of nitric acid and leave it for several days in a warm place (about 75°-80° Fahr.); then dilute with about 15 times the bulk of water, or so as to make a bath at 3° or 4° Twaddell. The skeins should be worked quickly through, and be removed promptly when the bleaching is complete, otherwise a permanent yellow stain would be produced. Remove every trace of acid in several waters, or running water. The method of bleaching with peroxide of hydrogen, or with oxygen itself, is said to be cheaper; but that I cannot say anything about.—NUN. DOR.

[60582.]—**Wood Bits.**—This is surely a matter for trial and experiment. The twist drills with lip and spur are specially designed for wood boring; but whether they would meet the requirements of "C. B." seems to me purely a matter for trial.—J. T. M.

[60591.]—**Tempering Springs.**—"Springee" is mistaken; the "stick" is of use in tempering, as it shows at what temperature to cool off. I don't think his "fun" (!) has given any one pain.—A SPRING SMITH.

[60598.]—**Etching applied to Die-sinking.**—It is possible to get raised lines on a steel die by etching away the other parts; but I suspect it would be more costly than the usual process. The lines would require frequent varnishing to prevent them being undercut by the acid, and it would need some experiment to determine the best acid or mixture to use.—SAML. RAY.

[60599.]—**Pinion Wire.**—This wire is drawn with corrugations, and is good enough for common work, especially when the die is kept in order; but it is not fit for use in fine watchwork.—D. G.

[60606.]—**Screw Thread on Thin Brass Goods.**—Your correspondent can spin or rub the thread up on a mandrel or "form" in the lathe; but in the factory it is done by a special machine. —SAML. RAY.

[60608.]—**Torpedo Defence.**—The nets are hung from projecting sprits about 18ft. from side of ship. The nets resemble a magnified piece of chain mail, the links being usually of galvanised iron of about 3in. mesh. But considerable variety of pattern exists.—NUN. DOR.

[60615.]—**Paring Machine.**—I should think a full brown would be the best temper for such knives—that is, as hard as possible with some amount of elasticity or springiness. It is a matter for experiment. I do not believe potash or any-

thing of the kind can have any effect.—SAML. RAY.

[60699.]—**Photo. Enlarging.**—If figure is clear of all the rest in group, cover them up and copy, enlarging to size desired. If not altogether clear of the others, most likely head and shoulders are. Cut out oval hole in white paper (if no better method suggests itself) by means of the letter "O" which will be found of proper size and shape in almost any newspaper. With this, cover the group showing head and shoulders through opening, and proceed as above directed; the result will be a vignette instead of a full-length copy of figure, which I think will meet the requirements of "Amateur Photographer." For instructions in copying and enlarging see Jabez Hughes' "Principles and Practice of Photography," older editions (9th edition, page 89).—R.

[60744.]—**Question in Dynamics.**—"W. A. S." is right and I am wrong. I had forgotten that the string when once set in motion must go on moving, as there is no friction or anything to stop it. Accordingly, the monkey would have much ado to hold his own, much more to make any progress up the string. If he stops trying to climb, he will go downwards with the string.—M.I.C.E., Bath.

[60744.]—**Question in Dynamics.**—In the replies to this query there seems to be considerable confusion between the (abstract) weightless rope and the (material) monkey at the end of it. The "monkey" seems to be in the problem, indeed (to use a popular phrase); but only as a means of shortening the distance between the two equal masses hanging from the said rope. Whatever force tends to shorten the rope, tends to raise both the monkey and the weight. And these two equal masses, acted on by equal forces, must move at the same velocity (by the laws of motion). Therefore, under the conditions of the problem as to friction, &c., the monkey will pull himself and the weight up equally, so that if they are level at starting they will always remain so, whether the monkey pulls in or slackens out the rope.—NEPHESH.

[60762.]—**Engine Flywheel.**—Yes; 6 or 7 horse nominal boiler should supply the engine, and 50lb. would suit. As regards driving saw, you will notice "Machinist" gives you good advice in this week's number. Act on it, and also go in for a new boiler, or, at the least, have it inspected by one of the many boiler Insurance Companies inspectors before purchasing. I presume you mean 1½in. bore pipe to supply engine. I should have nothing less.—T. C., Bristol.

[60781.]—**Corundum for Aluminium.**—It depends entirely on the price of the corundum, which contains, according to analysis, 68·90 per cent. of Al_2O_3. The greatest percentage of Al_2O_3 in kaolin to be obtained in Cornwall is 60·76 per cent., which can be purchased, I believe, at 20s. per ton.—F. W. GERHARD.

[60799.]—**Screw-Cutting.**—"H. O." is correct in saying my answer is wrong, as I should have written $d - 1\frac{1}{3}$ p. instead of $1\frac{2}{3}$ p. He may be correct as to his decimals, as they are also given in a book I have; but Molesworth gives height of thread = pitch, from which must be deducted $\frac{1}{3}$ of height, and therefore of pitch, for rounding top and bottom of threads. This amounts to $\frac{2}{3}$ p., or $\frac{2}{3}$ p. off 2 threads pitch—that is $1\frac{1}{3}$ p., as given above.—T. C., Bristol.

[60801.]—**Mechanical.**—TO MR. BOTTONE.—The resistance of bath, with electrodes of any given size in it, can only be obtained by actual measurement. The best means is by the aid of a Wheatstone bridge and a set of coils. See my advertisements in Sale Column.—S. BOTTONE.

[60816.] — **Gas-Engine.** — I had a ½H.P Otto which made noise the same as "Engine Driver" describes, and wrote makers, and they told me to file the gas supply valve (which is opened by the governor) hole inside a little larger—very little, to let engine have little more gas, which I found cured the noise complained of, and for six months or more hardly heard noise once a day. It has now returned again a little. I put it down to what A. Ricardo states in No. 1,129—viz., gas explodes in exhaust. Cleaning cylinder does not remedy it, as I tried before I wrote the makers; what they wrote me certainly cured my engine for the time.—YOUNG CUTLER.

[60817.]—**Windmill.**—(1) About one-fifth the energy of the wind is transmitted by the sails. (2) At different distances from the axis, the whips travel at different rates; therefore, the angles vary, to catch the wind at the best advantage. As much weather angle at tip would let all the wind slip by without pressure, owing to the velocity of the tip. These angles were carefully calculated and experimented on by Smeaton. (3) Horizontal and vertical mills, with sails to drive away from the wind, some with movable and some with fixed shelters, have been tried by many, but with little success, excepting a form invented and practically tried by Mr. P. Vallance, who described it in these columns some years back; and I have made some models (with six horizontal arms carrying vertical sails at the ends which set themselves to the proper angle for the wind automatically, and run back edge to wind with movable louvre boards controlled by a governor to always give nearly the same speed, and never requiring any part to be taken off in any wind) that worked very satisfactorily, and if I wanted power in a suitably windy place, I certainly should prefer a horizontal of this kind to the usual vertical, as giving off more power for space occupied, and they can be simply put on the top of the building, and catch the wind equally from whichever point it blows; when wanted to stop, one central rod opens all the louvre boards.—ALBERT COLLINGRIDGE.

[60820.]—**Chamber Organs.** — The specification of a chamber organ, given in your last issue by "Uranium," is good; but it seems to me that the same number of stops distributed over three manuals would give a more effective instrument. I inclose a specification of my own organ, which is satisfactory in every way. The 8ft. tone is full and rich, and the piccolo in the swell gives a pleasing brilliancy, which is in happy contrast to the screaming fifteenths to be met with on the great of some chamber organs I know. After several years' acquaintance with my organ, I do not know of any stop that I could add, or any that could be spared, without disturbing the perfect balance of tone. I should be very pleased to show my organ, or give any further particulars concerning it, to either "Taube" or "Uranium."

SPECIFICATION OF ORGAN.

GREAT ORGAN.
C C to G in alt. 56 notes.

1.	Open diapason, metal.........	8ft.	56 pipes.
2.	Clarabella, wood	8ft.	56 „
3.	Principal, metal	4ft.	56 „

SWELL ORGAN.
C C to G in alt. 56 notes.

4.	Open diapason, metal......... (Grooved to No. 5.)	8ft.	44 pipes.
5.	Rohr-flöte, wood and metal	8ft.	56 „
6.	Gemshorn, metal...............	4ft.	56 „
7.	Piccolo, metal	2ft.	56 „
8.	Oboe, metal	8ft.	56 „

CHOIR ORGAN.
C C to G in alt. 56 notes.

9.	Lieblich gedact, wood & metal	8ft.	56 pipes.
10.	Salicional .... (Grooved to No. 9.)	8ft.	44 „
11.	Wald flute, wood	4ft.	56 „

PEDAL ORGAN.
C C C to F. 30 notes.

12.	Bourdon, wood.........	16ft. tone.	30 pipes.

COUPLERS.

Swell to pedals.	Swell to great.
Great to pedals.	Swell to choir.
Choir to pedals.	Hydraulic engine.

Two composition pedals to great organ.
Two composition pedals to swell organ.

Pedals parallel and concave, radial sharps. Stop handles at an angle of 45°. Blown by Blennerhasset's "Perfect" hydraulic engine.—E. FRANKLIN ROOK.

[60821.]—**Battery Work — Erratum.** — An error appears in my reply to this query last week. "Adding a little nitric each time," should be, "adding a little nitre."—BOBADIL.

[60827.]—**Photography.**—I do not think that any photographic process, no matter how successful it might be, could reproduce the book in question, except at very great expense. I believe, however, that there is a chemical process of reproducing such work more exactly than photography can do, and at a very small expense. This process is worked, I believe, in London. A friend of mine would be pleased, I know, to give information on this subject to "S. R. C.," and I have taken the liberty of advertising his address in this issue.—MAC.

[60842.]—**Flat Music.**—Send them a copy of the ENGLISH MECHANIC, No. 1,119, and mark the diagram on p. 21 with a blue pencil.—N. E. CHILD.

[60853.]—**Artificial Teeth.**—If it is the intention of E. W. Gough to try and manufacture the above for himself, I fear, even with all the information he can procure, that it will benefit him but little; however, if the following will help him, I give it with pleasure. The materials used, are kaolin (white clay), silex, and felspar; none of these materials are fusible at a low temperature, nor, when fused, are they acted upon by acids; hence their extreme utility for artificial teeth. The various colours and shades are imparted by means of metallic oxides, in a fine state of division. In the process of manufacture—which is by means of moulds—small platinum pins are fastened into each tooth, by which means a piece of metal may be attached to the tooth and thus hard-soldered to the plate.—MOLAR.

[60854.]—**F.C.S., F.I.C.**—The secretaries of these societies will explain, on application.—SAML. RAY.

[60854.]—**F.I.C., F.C.S.**—The fellowship of the Institute is obtainable by anyone duly qualified who passes the requisite examination; the admission to the Chemical Society can *only* be had by certificate signed by at least five Fellows, three of whom testify to *personal knowledge* of the candidate.—F.C.S., Liverpool.

[60855.]—**Pulleys.**—"Amateur" must give more particulars as to how he proposes driving the planing machine—the flywheel has very little to do with that. He cannot do better than secure the recent Nos., in which full details of a planing machine were given, with sizes of parts and various methods of driving.—T. C., Bristol.

[60857.]—**Electro-plating and Coppering.**—Doctor your solution as little as possible. If the silver strips, the solution probably has too much cyanide. You might try it a little weaker. Too high an E.M.F. will also produce same effect. Carbons do not require any preparation, so that they are clean. Do not put much copper on them; a thin coating will hold when a thick one will come off. Use an acid solution for this. You do not say what batteries you are using. I cannot answer your last query, as I never deposited any copper on steel.—OS.

[60857.]—**Electro-Plating and Coppering.**—(1) The cause of the deposit stripping from German-silver articles may arise, not from any fault in the solution, but from defective preparation of the articles before immersion. Silver is very liable to strip from German silver, unless the latter has been treated with the mercury dip, after being thoroughly cleaned. (2) When you can wipe the deposit of copper from carbons, there may be several causes at work; such as too strong battery power acting through a weak solution, or too weak a current acting on a strong solution. A loose, sandy deposit is the result of a deficient current in a strong solution. Carbons require no special preparation, beyond having a few scores cut in their surface to give the copper a grip, and being perfectly free from anything that would hinder a deposit, such as grease or dirt of any kind. (3) An alkaline solution of copper should be used with a battery strong enough to give off gas at the cathode or article. Ammonia and cyanide should be added from time to time to keep the solution in good order. The anode gets coated with a blue powder when these are deficient. Too much ammonia, however, will prevent the copper from depositing, as it is redissolved. Too much copper causes the metal to come down as a powder. A good adherent deposit is obtained by hitting a happy medium. This is the best solution for steel articles; but being expensive, it is best, having given them them a mere film of copper in the alkaline solution, to finish off with the cheaper acid solution.—BOBADIL.

[60858.]—**Income-Tax.**—The mortgagor had no right to demand repayment of the whole of the Income-tax payable on the rent, unless the interest on the mortgage and the rent of the house are of the same amount, which is not probable. He can demand a deduction on the amount he pays "C. J. W.," which is £5 per annum. If the income-tax is 7d. per pound, this deduction will be 2s. 11d. "C. J. W." can again claim repayment from the Commissioners of Inland Revenue, seeing that his income is less than the taxable amount. Apply at the Surveyor's office of your district.—B.Sc., Plymouth.

[60859.]—**Weight of Modern Steamships.**—"St. Aubyns" is wrong in the application of his terms, for "dead weight" capacity means the cargo weight in tons which the ship will carry when loaded to her proper trim. The weight of the hull and machinery is little more than 33 per cent. of the total displacement to load line, and this percentage varies according to the size of ship, her fittings, and her class.—J. W.

[60859.]—**Weight of Modern Steamships.**—Unfortunately, I cannot give the weights of hull and machinery of the following vessels; but have given the displacements, with the hope that it may be useful to "St. Aubyns":—S.S. *Britannic*: length, 450ft.; breadth, 45ft. 2in.; mean draught, 23ft. 7in.; displacement, 8,500 tons; area immersed midships section, 926. Paddle-steam or *Connaught*: length, 327ft.; breadth, 35ft.; mean draught, 13ft.; displacement, 1,900 tons; area immersed midships, 336. H.M.S. *Agincourt*: length, 400ft.; breadth, 59ft. 5in.; mean draught, 24ft. 2in.; displacement, 9,071 tons; area immersed midships, 1,185. S.S. *Garonne*: length, 370ft.; breadth, 41ft.; mean draught, 18ft. 11in.; displacement, 4,635 tons; area immersed midship, 656. Paddle-steamer *Mary Powell*: length, 286ft.; breadth, 34ft. 3in.; mean draught, 6ft.; displacement, 800 tons; area immersed midship, 200. S.S. *Africa*: length, 130ft.; breadth, 21ft.; mean draught, 8ft. 10in.; displacement, 370tons; area immersed midship, 148.—ENGINEERING, Manchester.

[60860.] — **Turbines.** — I have not critically examined the formulæ in this book; but if there are so many careless mistakes on two pages, one must use great circumspection in working from the formulæ given in it. (1) The first formula should be $60 \frac{Q\ H}{700}$ or $\frac{Q\ H}{11{\cdot}67}$ = H.P. at 75 per cent. (2) In the note on page 33 read $\frac{Q \times 60}{\sqrt{H} \times 2{\cdot}08}$ (3) $r = d \times 3{\cdot}6$, as is obvious from the examples. The "course I have adopted" since you have called my attention to these mistakes is to check them and alter. Mr. Cullen ought to be greatly obliged to you for writing to him to point them out.—GLATTON.

[60862.]—**Parallel Motion.**—If your measurements are correct, the links are not parallel, as their centres are 7ft. 4in. on top, and 7ft. 6in. on bottom; the parallel rods should be 7ft. 4in. long, the radius rods will then be 11ft. 5½in. long. This error is not, I think, enough to account for such a bad motion as you describe. When at half-stroke, the centre lines of beam, of parallel rods, and of radius rods should all be parallel. Is this so?—GLATTON.

[60862.]—**Parallel Motion.**—I presume half length of beam is 16ft. 8in., instead of as printed. If so, length of radius rods should be 11ft. 2½in.; but more probably the main bearing brasses of beam and brasses in each end of connecting rod are worn. Put piston to bottom and top of stroke, making a light scratch on rod, and find exact half-distance, and send piston down to this mark. Now see if centre of cross head, and also centre of radius rods, are in the same horizontal line; if not, adjust either brasses or the centre.—T. C., Bristol.

[60863.]—**Legal.**—C. Ensor should cut his hedges when he thinks proper. It appears he has a title to them, and if his neighbour also claims the ownership, it will probably turn out that the hedge is joint property, and can be cut by either party when necessary.—B.SC., Plymouth.

[60865.]—**Mathematical.**—Take the expression $y = \frac{1}{x-3}$ for an example. If we make $x = 3$, one might say that y ceases to exist, for the case of a divisor equal to 0 has no sense in itself. But if we suppose that x increases from 2 so as to approach 3 as near as we choose, then it is evident that y will increase without cease in absolute value, so that when $x = 3$ we find y has become equal to ∞; when x increases from 2 towards 3, then y can be said to tend towards $+\infty$; when x decreases from 4 towards 3 then y tends towards $-\infty$.—WIS.

[60865.] — **Mathematical.** — The equation $y = \frac{1}{x}$ is the simplest example of what is required. If all values were given to x from 0 to both positive and negative infinity, and the resulting curve plotted, we would get a double curve. First suppose we give all positive values to x; the smaller x becomes the greater does y become, and when $x = 0$ y becomes positive infinity. Again, give all negative values to x: as before, the smaller x is, the greater will y be; but this time y will be negative, and when x becomes 0, y becomes negative infinity. y is therefore said to pass through all values, passing through $\frac{1}{0}$ or $\pm$ infinity when changing its sign.—M.I.C.E., Bath.

[60867.]—**Photographic.**—I have not yet tried it; but I have been recommended to use citric acid for this purpose.—GLATTON.

[60867.]—**Photographic.**—Rub the fingers over with a saturated solution of citric acid, or a lemon may be used instead. For further particulars refer to back numbers, where I have given this same answer to query more consideration.—A. TREYER EVANS.

[60867.]—**Photographic.**—Cyanide of potassium is the best remover of photo stains, but it is a dangerous poison. I would recommend the use of the sodic sulphite developer, which does not stain either the plates or fingers. Many formulæ are given in back numbers. Beach's is as good as any.—B.SC., Plymouth.

[60870.]—**Horsehair.**—I should say that to make rope from horsehair (if this is what the querist means, as he says "rope hair") a rope-making machine would be required. This can be seen on any rope-walk.—OS.

[60872.]—**Wooden Chucks.**—The best wood for making chucks I find is beech or box, and as for getting the grain to answer your centres, I don't think it matters much if it is a little the one side. The best wood for turning speed-pulleys is *lignum vitæ*—it is the best wood I have found not to split.—YOUNG TURNER.

[60872.]—**Wooden Chucks.**—Boxwood chucks grain to run in line of centres, and woods with a long grain across lines of centres. Mahogany or any hard wood will suit for pulleys, and the speeds should be so proportioned for gut to fit all three speeds, unless you require one slow speed, in which case it should fit the other two.—T. C., Bristol.

[60872.]—**Wooden Chucks.**—Much depends on the size of chuck. Very often the "plankway" is a matter of necessity, but there is another matter of consideration, and that is the screw. This will be best plankway in such woods as beech, ash, elm, &c., but in box, for every reason the wood will be cut the other way, as the screw-thread will be excellent, owing to the close grain. Acacia, if dry, takes an excellent thread. Beech also will hold a thread good enough, but in this, and other cases, the chuck has to be trued up each time it is used. If a common wood-screw is inserted in the end—i.e., parallel with the fibres of soft wood, it has little hold, as it can often be pulled straight out, bringing the fibres with it; screwed in "plankway," it holds firmly. This shows us which way is best, but as a mandrel carries a coarse thread, the chucks can be made to answer either way. With a traversing mandrel and an inside V-tool, you can cut a good thread in such soft woods either way, and a good thread is the secret of a lasting fit; but few would take this trouble in the case of the above woods, because chucks do not need to last long. A hollow tap, sold by Hines, will cut good screws plankway in beech, but less satisfactorily the other way. One more consideration is the fact that if you make a plankway chuck to hold work to be driven into it, you will be likely to split it, unless you put on a ring outside. For my own part, in the case of small chucks up to 3in., I use all sorts of wood cut off the end of a log. For chucks four, six, or more inches, a bit of beech plankway, but probably on the iron face-plate. I made a dozen acacia chucks a few days ago, and the thread is excellent, but I always expect to true up chucks not made of metal or boxwood. Turn the speed pulley of beech or mahogany, and let gut fit all speeds.—O. J. L.

[60875.]—**Small Medical Coil.**—TO MR. BOTTONE.—The brass flange will affect the working of the coil very injuriously. But if the clapper vibrates at all, and the coil is properly made, a most violent shock would be given when joined up to two bichromate cells, provided they were all right. There must be something wrong besides the brass flange, either leakage or wrong connections.—S. BOTTONE.

[60876.]—**Bottling Cement.**—Melt gelatine or fine glue in a glue pot as for ordinary use, and add a very small quantity of glycerine, just sufficient to keep it from getting too hard when dry. A little aniline colour of some kind will improve it. Dissolve the colour in glycerine, add a little water, then mix this with the melted gelatine. Fine white glue will answer every purpose, soaked in water before being melted.—OS.

[60877.]—**Finishing Cast Steel in the Lathe.**—Cast steel frequently differs. You may have mild cast steel or hard cast steel, according to maker; but supposing it to be mild, then you could take a finishing cut without any water or oil, but dry. But supposing it to be hard, use water and soap; but if you have too much surface on your tool you will find that it will scratch, and if this should happen, you had better leave a very little on, so as you can file the marks out; but if you use oil, you will find that the cut will work off the job.—WALLACE NEWLAND.

[60880.]—**Boiler Supply.**—I think the water company will object to the proposed arrangement Your best plan is to have the usual tank above fitted with a ball-cock, and will be cheapest in the end, as the supply-cock would certainly be forgot to be used at some time, and at the very least burn your boiler for you.—T. C., Bristol.

[60880.]—**Boiler Supply.**—The chief objection I see is that the boiler would be almost absolutely certain to explode before it had been fitted a year. A frost might stop the inlet, the steam would have no outlet, and bang would go the boiler; a little fur in the pipe would supply the necessary stoppage without a frost. This arrangement is nearly identical with that often adopted for the supply of hot baths. Safety-valves are generally fitted by good plumbers; but explosions are not infrequent. Another objection would be that if the inlet was not clogged, the steam would probably drive all the water out of the boiler, and the latter would then burn through. If tap on supply was shut off, the effect would be an explosion, as before. Of course, in the above I am supposing you to mean that the boiler is watertight on the top, and the water is always turned on under pressure from the main, unless shut off for repairs to boiler, &c.—GLATTON.

[60884.]—**Textbook on Mechanics.**—Our own columns—viz., the "Amateur Workshop," giving full working instructions on making an engine and planing machine are as good as any I know; but Cameron Knight's "Mechanical Manipulation" gives good insiruction on lining-out work, which, if well done—and worked to—is about all you can expect to learn from books. Shelley's "Workshop Appliances" gives details of lathe gear, and, I think, slotting machine.—T. C., Bristol.

[60885.]—**Scissors Grinding.**—Grind only the one edge to about 70°. Make them "walk and talk"—that is, give a slight curve to the blades, so that—being riveted or screwed when open—as they are closed the edges keep in contact from heel to point, and give that peculiar, smooth grate noticed in a new pair of scissors.—T. C., Bristol.

[60890.]—**Master Keys.**—Chambers's "Etymological Dictionary" says of the word padlock, "a lock for a gate opening into a *pad* or path; a lock with a link to pass through a staple or eye, perhaps, from Anglo-Saxon, *paad* a path, and lock, according to Wedgwood, a lock hanging like a clog to an animal's foot—low latin *pedana*, a clog—Latin, *pes*, *pedis*, the foot." I may note that Spurrell, in his "Welsh Dictionary," gives "pad" as "what keeps together." May this be a clue?—ARTHUR MEE.

[60891.]—**Insulation of Battery Boxes.**—TO MR. BOTTONE.—The Post Office pattern is a teak trough, insulated with marine glue.—S. BOTTONE.

[60892.]—**Annuity and Estate.** — In your propositions you omit an important particular—viz., the rate per cent. the purchaser is to be allowed to make of his money. Taking, however, the rate to be 5 per cent., the workings and results would be as follows, assuming the annuity to be paid once a year:—

Let A = the annuity in pounds sterling.
r = the amount of one pound and interest for one year; or $1 + t$, in which t = the rate per cent. (in the present case $r = 1 + {\cdot}05$).
n = the number of years.
P = the present value.

Then, by formula, $P = \frac{1 - r^{-n}}{r - 1} A$

We have— $$P = \frac{1 - 1{\cdot}05^{-32}}{1{\cdot}05 - 1} \times 115.$$

First find the value of $1{\cdot}05^{-32}$

$1{\cdot}05^{-32} = \frac{1}{1{\cdot}05^{-32}}$; $\log. \frac{1}{1{\cdot}05^{-32}} = \log. 1 - 32 \log. 1{\cdot}05.$

Which we state as follows:

$$\begin{aligned} \log. 1 &= 0{\cdot}0000000 \\ 32 \log. 1{\cdot}05 &= 0{\cdot}6780576 \\ \log. 1 - 32 \log. 105 &= \bar{1}{\cdot}3219424 \\ \log. {\cdot}20956 &= \bar{1}{\cdot}3219297 \end{aligned}$$

Therefore, to five places of decimals $1{\cdot}05^{-32} = {\cdot}20986$. The fraction now takes the form—

$$\frac{1 - {\cdot}20986}{{\cdot}05} \times 115 = \frac{{\cdot}79014 \times 115}{{\cdot}05} = 1817{\cdot}3.$$

Therefore the present value of the annuity of £115 for 32 years, allowing the purchaser 5 per cent., is £1,817 6s. 8d. The question may be solved by Inwood's tables, almost by mere reference. We find in Table I. (p. 6 of ed. 1884) under the head "Years' Purchase at 5 per cent.," and on line with 32 years, the length of the term of this annuity, the figures 15·803. This is usually called the number of years purchase, and multiplied by 115 will give 1817·3 the value. The 15·803 is truly the present value of an annuity of £1 for that term. To find the value at 4 per cent. we will take up the calculations at the point—

$$\begin{aligned} \log. 1{\cdot} &= 0{\cdot}0000000 \\ 32 \log. 1{\cdot}04 &= 0{\cdot}5450656 \\ \log. 1 - 32 \log. 1{\cdot}04 &= \bar{1}{\cdot}4549344 \\ \log. {\cdot}28505 &= \bar{1}{\cdot}4549210 \end{aligned}$$

$\therefore$ to five places decimals $1{\cdot}04^{-32} = {\cdot}28505$

Our fraction then becomes—

$$\frac{1 - {\cdot}28505}{{\cdot}04} \times 115 = \frac{{\cdot}71495 \times 115}{{\cdot}04} = 2055{\cdot}5$$

Therefore the value at 4 per cent. is £2,055 10s. Taking the figures from Inwood's tables under the 4 per cent. column, we find 17·874 years purchase, which multiplied by 115 gives 2055·5. For your second question, as to the value of a freehold of £65 annual rental, we will refer to the formula above used: $P = \frac{1 - r^{-n}}{r - 1} A$. Here in a freehold the number of years is infinity, and, therefore, r^{-n} or $\frac{1}{r^n}$ becomes infinitely small, and may be disregarded, so the formula becomes $\frac{1}{t}$.A.

In the case of 5 per cent., therefore the value is—

$$\frac{65}{{\cdot}05} = 1{,}300 = £1{,}300$$

and in the case of 4 per cent.—

$$\frac{65}{{\cdot}04} = 1{,}625 = £1{,}625.$$

If you wish for the steps leading up to the formula I have used, I shall be happy to give further work-

ings out, or refer you to mathematical works on the subject of compound interest and annuities.—SURVIVOR.

[60892.]—**Annuity and Estate.**—Annuity at 4 per cent. = £2,058; freehold at 4 per cent. = £1,625.—BREAM'S BUILDINGS.

[60893.]—**Cement.**—I have seen a mixture of putty, white lead, and a little red lead used for this purpose. It ought to make a very good joint if properly used.—OS.

[60893.]—**Cement.**—The querist may use equal parts of resin, pitch, and plaster of Paris; or powdered clay three parts, oxide of iron one part, and boiled oil, to form a stiff paste.—A. TREYER EVANS.

[60894.]—**Varnish Brush.**—Soak it in methylated spirit.—OS.

[60894.]—**Varnish Brush.**—Varnish and paint brushes can be cleaned in a warm solution of washing soda and water.—W. S.

[60894.]—**Varnish Brush.**—Put the brushes in alcohol. If the varnish is a turpentine varnish, put them in turpentine. For ordinary cleaning of paint-brushes, &c., soap well, and put into strong hot solution of soda.—SAML. RAY.

[60895.]—**Dynamo.**—TO MR. BOTTONE.—The dynamo as described would do for either arc or incandescent. If shunt be desired, then wind the F.M.'s with 10lb. of No. 22. If you use the dynamo as a motor, you will most likely reverse its polarity, and ruin it as a dynamo.—S. BOTTONE.

[60896.]—**Coil.**—TO MR. BOTTONE.—Yes, to all questions. "W. P. W." will get good effects from his coil if he uses a condenser made from 50 sheets of tinfoil about 3in. by 5in.—S. BOTTONE.

[60899.]—**Chemical.**—The reaction between potassium bichromate and iron proto-sulphate in a solution containing sulphuric acid may be represented by the following equation:—$6FeSO_4 + K_2Cr_2O_7 + 7H_2SO_4 = 3Fe_2(SO_4)3 + K^2SO_4 + Cr^2(SO_4)_3 + 7\,H_2O$. No reaction would occur without the presence of free acid in sufficient quantity.—F.C.S., Liverpool.

[60899.]—**To Chemists.**—

$$(1)\ aq + FeSO_4 + Ba(NO_3)_2 = Fe\,(NO_3)_2 + BaSO_4.$$

$$(2)\ \underbrace{5FeSO_4 + 2K_2CrO_4 + 3H_2S + 2H{\cdot}O}_{aq} =$$

$$\underbrace{5\,Fe\,(OH)_2 + 2K_2SO_4 + Cr_2\,(SO_4)_3 + S^2.}_{aq}$$

—WIS.

[60902.]—**Gas Furnaces.**—If "E. R. D." had written to me about his difficulty I could have told him at once that his foot-blower is much too small for the size of furnace he uses. He must of necessity have a blower of proper size and power if he wishes to succeed with his melting.—THOS. FLETCHER, Warrington.

[60903.]—**Motions of Earth and Moon.**—The statements in the *Encyclopædia Britannica* are quite correct, and follow from Newton's laws of attraction and reaction. The mass of the earth being forty times that of the moon, their common centre of gravity will be in the line joining their centres in such a position that its distance from the moon is forty times its distance from the earth. The moon's distance being 240,000 miles, the distance of common c.g. is found to be 6,000 miles from the earth's centre, and the diameter of the orbit double this. It is this common centre of gravity which revolves in an approximately elliptic orbit about the sun, and not the centre of the earth. At each full moon the centre of the earth is 6,000 miles within the orbital ellipse, and at each new moon 6,000 miles beyond it.—R. E. F.

[60906.]—**Lens.**—I have used the lens you mention (Wray's 5in. by 4in. rectilinear) for the purpose you require, and do not think a better instrument can be found for such work.—J. H. B., Penzance.

[60906.]—**Lens.**—"Enquirer" will find Wray's 5in. by 4in. rapid rectilinear answer his purpose well; with the exception of portrait lenses, it is the most rapid lens yet produced. I took some admirable pictures of cats at about 5ft. distance on half plates with one of these lenses last February on Edwards's most rapid plates and drop-shutter exposure. At 8ft. distance an object a yard long would be represented on the plate about $2\frac{1}{4}$in. in length, and at 6ft. rather more than 3in.—T. PERKINS, Shaftesbury.

[60908.]—**Boiler.**—This seems to be aiming too high for a beginning. I should advise you to make something smaller first. Say you buy a set of castings for a 1in. by $1\frac{3}{4}$in. engine, which you can get for about 4s., and when finished make a boiler 12in. by $4\frac{1}{2}$in., having a single tube 2in. diam. through centre. Lag the boiler and use a gas jet inside tube, and you will get plenty of steam. Make boiler of No. 20 sheet brass, and rivet and sweat the seams with solder, and work at 20lb.—T. C., Bristol.

[60909.]—**Mangle Rollers.**—The cause of roller-shafts working loose in machine must be badly-seasoned timber. Remedy: Go to the nearest smithy's shop and get an iron ring made about 2in. smaller than diameter of roller; insert this in the end of roller little under level, wedge carefully between this and shafts with about six wedges either of good hard English oak or iron, keeping a steady eye on shafts so as to keep them perfectly in centre of roller.—BLANKET.

[60909.]—**Mangle Rollers.**—Clean out inside of rollers, bind tightly round spindle rather thin twine, keeping it the same thickness throughout, till just large enough to enter rollers tightly; then heat rollers and spindle in an oven, and soak spindle with melted pitch; then, while hot, insert spindle by pushing and turning continually opposite direction to that of winding the string. For indiarubber or wooden rollers, tried 18 months ago.—A. J. E.

[60910.]—**Screw-Cutting.**—"O. J. L." is in correspondence about this apparatus. The inventor writes that he has simplified and improved it, and will be in a position to manufacture it for sale very shortly; the original apparatus on "O. J. L.'s" lathe never fails to work well, and if it is improved at all it ought to be a grand success, for it is excellent in its old form. The moment permission is given "O. J. L." will fulfil his promise gladly, as he is greatly interested in the contrivance.—O. J. L.

[60911.]—**Steam Engine.**—You must give particulars as to travel of valve, sizes of ports, and also if there is room in valve-chest to allow of more travel of valve. You can effect a cut-off to, say, $\frac{5}{8}$ of stroke by setting eccentric forward and putting lap on steam edge of valve, and travel of valve should be increased if possible. Can say no more without further details.—T. C., Bristol.

[60913.]—**Cheap Dynamo.**—TO MR. BOTTONE.—Full instructions have been given as to the construction of such a dynamo at pp. 1, 46, 94, *et seq.*, of the ENGLISH MECHANIC, Vol. XLIII. If you do not understand these, write to me again, and I will try to clear away your difficulties. The best way to drive is by a steam-engine: the next best water-power or a gas-engine; then a windmill. If you use an electric motor you must use a battery or another dynamo to drive the motor; and since you always waste some power in transformation, you would actually get less light out of your dynamo, driven from a motor and battery, than you would out of the battery if used directly with the lamps.—S. BOTTONE.

[60917.]—**To Mr. Wimshurst.**—"J. B." will find it safer to use wood for the top of the case. A glass top is liable to get broken, and its pieces in falling may injure the discs. The proper thickness of the discs depends upon their diameters, 13oz. glass, or not more than one sixteenth of an inch thickness glass, does very well for discs up to 20in. diameter. Mahogany will not answer for the handles. Thick brass wire will do for the collecting combs: it does not require shellac varnish—simply polish and lacquer it.—J. W.

[60918.]—**Screw-Cutting.**—In cutting odd pitches you should, when all ready for starting, make a chalk mark on bed of lathe at end of saddle, also a mark on top of face-plate, and one on top of change-wheel on leading screw. By bringing all these marks in same relative position at each cut, the thing is done.—T. C., Bristol.

[60918.]—**Screw-Cutting.**—"Chalk your bobbins." I mean to say, chalk-mark your mandrel and head-stock, and also the leading screw-wheel and its bearing. Do this when ready to take first cut, and also drop a piece of wood, cut to width, between carriage and tailstock. Now take your cut, run carriage back till it touches the wood, and run your lathe until the two pairs of chalk-marks coincide. Now your lathe is in the same position as in starting, and the half-nut will be again in position for grasping the right threads of the screw. By a little practice in watching the chalk-marks as they come into view, you will (if a power-lathe) be able to start the carriage at the right moment without stopping the lathe; but do not run any risks with so fine a screw—NEPHESH.

DR. A. FOTTINGER has found chloral hydrate to be a good medium for preserving polyzoa and the lower animals. In the case of polypa, when fully expanded, crystals of chloral hydrate are dropped into the water, and in the course of a short time the colony becomes insensible, when the specimen may be placed in alcohol without any contraction or change of form. Star fishes may also be treated in the same manner to advantage. The chloral seems to act as a narcotic from the effects of which the animals may recover.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

QUERIES.

[60919.]—**To Mr. A. H. Allen.**—(1) Could you please give a quantitative method of determining the borax and boracic acid in a mixture of the two? (2) Why in calculating the percentage of foreign fat present in a butter, do you direct (page 235, foot-note, Vol. II. of your admirable "Commercial Organic Analysis") to use the formula there given? Why multiply by 13·3?—E. G.

[60920.]—**Mangel Wurzel.**—Will some correspondent conversant with the chemistry of the root tell me if there is a particular time when sugar gets developed in it, or is sugar always present and develops concurrently with rest of the root? When is the most profitable period to give the root to cattle—fresh from the ground when the leaves are still on, or after the root has been stored for a considerable time?—AMATEUR.

[60921.]—**Petroleum Spray.**—Will any reader tell me how I can make an effective sprayer for spraying petroleum by steam, so that when the steam and petroleum mix they will burn? Some time ago, I saw the furnace of a small engine burning steam and petroleum in the form of spray, and I have since tried to make a similar sprayer, but, so far, not with success. Will any reader inform me how to make the best form of sprayer for the purpose?—ERNESTO.

[60922.]—**Albatross Skin.**—A fine specimen of the above has been given me pretty much in the condition it was taken off the bird—i.e., with a lot of grease about the roots of the feathers on inside of skin. Will someone tell me in detail how to dress or cure it, and suggest a few things it might be made into? It is much too large for a lady's muff. It is a sort of white elephant in my hands; still it seems a pity it should not be utilised in some useful or ornamental manner, inasmuch as the bird has been deprived of it.—RARA AVIS.

[60923.]—**Simple Screw-Cutting Apparatus.**—Would "W. E. D." (letter 26430) kindly say if this is made for sale, or, if the whole apparatus is not sold, where one could get the circular cutter. It seems an admirable notion, and would, I should think, be readily bought by amateurs, if advertised.—C. H. C.

[60924.]—**Portable Electric Light.**—Will any of "ours" inform me how many cells of the chloride of silver cell (silver and zinc plates, 4in. by 2in.) would light a 2-candle-power incandescent lamp, and how long it would last with one charge?—SEPTO.

[60925.]—**Violin Query.**—Will any reader of the "E.M." kindly tell me if there is any advantage in making the back of a violin in two pieces, and also if the usual grain of the wood of which violins are generally made is essential to good tone?—NOISE BOX.

[60926.]—**Hokey Pokey and Coker Nut Candy.**—Will any kind reader inform a poor widow-woman how to make the above?—POOR WIDOW.

[60927.]—**Re-cutting Chasers.**—Could any of "ours" inform me how to re-cut inside and outside chasers—the best method?—NOVICE.

[60928.]—**Reversing Gear to Motor.**—Will any reader kindly tell me whether I could reverse motion of a Cuttriss' motor at pleasure? I have tried changing poles of battery; but motion is in same direction—no matter how joined. Perhaps such a thing could not be done. Please help—A COUNTRY PARSON.

[60929.]—**Nickel Plating.**—Will someone kindly tell me how I can dissolve nickel and prepare it for electro-deposition in the bath? I have a book on silver electro-plating, but do not know if nickel is treated in the same way. Can aluminium be deposited on another metal, and will it prevent rust or tarnish when in contact with water?—DAVID.

[60930.]—**Triangular Tool.**—Will some reader please inform me how to make triangular tool for lathe, with sketch, if possible? Also parting tool?—BEGINNER.

[60931.]—**Bicycle Making.**—I am thinking of building a bicycle; but not being a rider, am doubtful as to the best size, &c. My height is 5ft. $9\frac{1}{2}$in., weight about 11 stone, and measure 2ft. $9\frac{1}{2}$in. in fork, standing upright, without shoes. I think I ought to ride a 54in. easily; but I am anxious not to get one too high. What is the best method of building driving hub? The modern ones appear to have the gunmetal hubs bored and then soft-soldered on the axle. I propose putting plain bearings in, but do not quite understand the cone principle as applied to them

Should the axle be hardened, and, if so, will it temper, or must I caseharden? Are hollow forks of real advantage? I do not see anything relating to this subject in the last few back volumes that I have, but shall be glad of other back references.—MIDNIGHT OIL.

[60932.]—**To Anyone who Knows.**—How is the inlaying done that is used to decorate the shelves of walnut whatnots, such as are frequently brought to the door in the country for sale? The inlay is white, and apparently let into real walnut, well faced and polished. The price asked may be 14s., or less, for four shelves supported by twelve pillars of stained wood. The inlay is not deep, nor is the walnut perforated, as in marquetry, where three or four veneers are cut, and each becomes the inlay of its fellow. Surely it could not pay to chisel out the matrix. Even the errors, such as badly-shaped curves, are repeated in each. The inlay is not paper, for I have picked out a chip.—O. J. L.

[60933.]—**Gut Driving Bands.**—Will "Hendon" please give fuller description, and how to make, if possible, the lathe band fastening mentioned by him in "E.M.," Nov. 8th?—BEGINNER.

[60934.]—**To Mr. Bottone or Mr. Eaves.**—I have an ordinary electro-magnetic machine. I am unable to obtain a current from it. It seems apparently short-circuited. I believe the spindle carrying the coils should be insulated one end. Mine is made as follows: the cross piece of iron carrying the coils is insulated from the spindle, and pivots of spindle work in insulating pieces each side of frame. What should the resistance of coils be, and how shall I connect coil ends? The magnets of this machine are good.—G. R. H.

[60935.]—**Aluminium.**—Can any reader inform me if there is a yellow aluminium leaf which can be substituted for gold leaf? Want something to come in cheaper than gold. Have tried Dutch metal, but it tarnished so soon. Want something that will not tarnish.—A. L.

[60936.]—**Oxygen.**—Will any reader kindly inform me what heat is required to make oxygen gas from oxide of manganese alone, and whether gas so made is as good for optical lantern work as that made from chlorate of potash? Also, does the gas require purifying in any way?—W. M. B.

[60937.]—**Photography.**—Could any reader of "ours" inform me how to copy lantern slides by the powder process?—AMATEUR PHOTOGRAPHER.

[60938.]—**Photography.**—What is the difference between burnishing machines and glazing machines? Which are the easiest worked, and which would be the best of the two for an amateur to purchase? Would some practical photographer advise?—B.

[60939.]—**Casting of Gunmetal upon Wrought-iron Shafts.**—I should be extremely obliged for information from anyone who has had experience in casting of gunmetal upon wrought-iron shafts. We have lately had to cast some sleeves, 20in. long and 5in. diam. outside, upon wrought-iron shafts that are 4in. diam. and 9ft. long. Two sleeves were cast upon each shaft; but we have not been very successful with them—there was always a number of air-holes in the gunmetal, caused, I believe, by air from the wrought iron. We have now some wrought-iron spindles to encase with gunmetal the entire length. The spindles are about 23in. long and 1¼in. square, with the corners flattened. The gunmetal to be cast on them will be 2½in. diam. I am afraid we shall have the same trouble with these, so should be glad to have some advice before commencing them. Our mode of casting this kind of work previously has been: after the mould is made and skin dried, the wrought iron is made hot, and at once placed in the mould. The metal is then poured in before the shaft has time to cool; but we have invariably found air-holes in the castings. These have had to be burnt afterwards by a continuous flow of metal in the usual way, but having to patch the castings is not satisfactory. I should be glad to have any practical advice from a brother mechanic how these air-holes may be prevented.—MOULDER.

[60940.]—**Oxalic Acid.**—I am desirous of making some oxalic acid on a large scale for commercial purposes, and shall esteem it a favour if any fellow reader will tell me the amount that may be produced from a ton of sugar, and how much nitric acid it will take. In what vessels (lead or iron) should the operation and evaporation be carried on, and are the nitrous fumes allowed to waste, or can they be converted into anything commercially profitable? Any information will be thankfully received. Are there any books published that will give particulars of manufacture from sugar and sawdust? How much can be produced from a ton of sawdust?—J. MONTAGUE JACQUES.

[60941.]—**Fire.**—My inquiry of 15th Oct. concerns two old people, both invalids, living alone in a small cottage house. The wife finds the cold of the kitchen, before the fire burns, very trying in winter, and I am anxious she should be able to keep it in during the night, if it be possible. I have been making inquiries about the Edford briquettes, but find they will not stand so long a journey. Ilkeston and Derby Brights are new names to me. I wonder if they resemble a kind of coal we know as Cannel. My old friends spend a good deal of time in bed. The fire might have to burn 11 or 12 hours without being looked to.—E. G., Liverpool.

[60942.]—**Spirits of Wine.**—Having a small still, can I make lamp spirit from sugar satisfactorily? Kindly give practical directions.—J. B.

[60943.]—**Power to Grind Coffee.**—I find I exert 1500 foot-pounds per minute in grinding my coffee every morning. Will Mr. Seal's hot-air engine do this work? I see he advertises a small one in the Sixpenny Sale Column. H.

[60944.]—**Copper Green.**—Will some chemical friend kindly tell me the quickest way to get a deep copper green into candle material?—PARAFFIN.

[60945.]—**Working Model.**—Will any reader kindly give dimensions and sketches of the working parts of model horizontal slide-valve engine—cylinder 1in. by 2in.?—F. BOTTOMS.

[60946.]—**Locomotives.**—Will any reader kindly inform me what the consumption of fuel per train mile of 7ft., 5ft. 3in., 4ft. 8½in., 3ft. 6in., 3ft., and 2ft. gauge locomotives, and if peat is used as a fuel on any of the Irish railways mixed with coal?—C. D.

[60947.]—**Chloride of Silver Cell.**—Will Mr. Bobadil kindly answer the following:—Why is unslaked lime used in this battery and 1oz. of chloride of silver? For how many cells will this do? The cells round inside 1 by 2½in. How many minutes will the cell keep a constant current?—HOLLAND.

[60948.]—**Electric Indicator.**—I should feel much obliged if any reader would kindly send sketch showing connections of an indicator with electric replacement for four rooms.—H. E.

[60949.]—**Repolishing Gun Stocks.**—Would any of "ours" versed in gunnery give me a few hints on doing the above in a satisfactory manner? Also the way in which the stock is cut, and what substance gunsmiths fill in the nicks or cuts? I have seen some where a kind of red substance seemed to have been run in. I would be very glad of an answer from "Armourer," if he would be so kind.—J. W. B.

[60950.]—**Tricycle House.**—I have a well-built house for tricycle made entirely of match-boarding, well fitted, including floor, and standing on bricks to allow current of air underneath. Not a particle of rain could enter anywhere, and the boards inside are always perfectly dry to the feel; but the machine, particularly the nickel parts, suffers from damp very much. Kindly say which is the best means of remedying this. Would a few holes drilled at either end or along one side be sufficient? Should also be glad to know what to coat the nickel with during the winter to keep it nice.—TRI.

[60951.]—**Electro-Deposition of Copper.**—Will some expert mention the cause of, and remedy for, the following? On cathode of bismuth 1, tin 2, no deposit takes place, and the surface is eaten away. The same solution, acid sulphate of copper, giving perfect deposit both before and afterwards on ordinary type metal. I should mention that connection was made with battery in each case before insertion. The first-named alloy takes a far higher polish, which makes it preferable for the purpose required.—A. B. COTTON.

[60952.]—**Lathe Matters.**—When examining an anti-friction chain connection between the treadle and crank of a lathe, it occurred to me that we might easily substitute an eccentric for the crank. This would be an advantage to amateur lathe makers, as no forging would then be needed, and the shaft could be made much lighter. I should like to know the opinion of "O. J. L.," or other of our lathe men, as to whether it will work well.—L. H. R.

[60953.]—**New Electric Machine.**—I very much like the looks of the machine described by "A., Liverpool," but as I do not quite see the theory of it, I should be obliged if he would enlighten me on a few points. Ought there not to be a piece of brass similar to A (Fig. 2) in front of the top rubber? What ought these to be connected to? What is lining paper, and what size and number of sparks per minute can be got from the machine described?—L. H. R.

[60954.]—**John Wilkinson, Iron Master.**—I have in my possession a copper coin or token, somewhat over an inch in diameter, on the obverse side of which is a bust of "John Wilkinson, Iron Master," in profile, the name and designation appearing around the head near the edge of the coin. On the reverse side is a representation of the old-fashioned tilt forge hammer and furnace, and a forgeman manipulating a "heat" on the anvil, the year 1787 being placed below. Around the edge of the coin are the names "Willey," "Snedshill," "Bersham," and "Bradley." I shall be glad if any of your readers can give some information regarding it, and the purpose for which it was struck.—OXIDE.

[60955.]—**Steam Hammer.**—I have a steam hammer. The piston, piston rod, and hammer head weigh 5cwt.; the dia. of cylinder, 10¾in.; stroke, 2ft.; and boiler-pressure, 40lb. What blow will this hammer strike? I wrote to you on the same subject a few weeks ago, and you referred me to some back numbers, where I found the formula for the weight of a falling body, which, if I apply it to my hammer, gives something like 20 tons, which I think far too great. The steam is, of course, admitted throughout the stroke, and I added this total pressure to the 5cwt. Am I right in doing so? I remember a condenser falling 2ft. which weighed 16 tons, and this shook the place. My hammer surely does not give a blow equal to that.—FORGE.

[60956.]—**Corn Thresher.**—I should like to know the proper way of balancing a corn threshing drum, so that it may run quite steady when at a very high speed.—J. P.

[60957.]—**Pitch.**—Supposing the pitch to be given to find the diameter line, how is diametrical pitch worked out? Where ought the pitch line of a V-thread pitch line to be—either top, centre, or bottom? Please give the best book on wheel gearing, and the price.—H. G. NURSE.

[60958.]—**Crutch Slipping.**—At the bottom of my crutch I use a piece of indiarubber for ease to the arm, and to prevent the thud when walking. In wet or greasy weather the crutch slips very much with the rubber on, as I do not use the crutch directly perpendicular. Can anyone suggest any material that would answer as well, but not slip when the flags are greasy, or assist me in any other way with a remedy?—MAGNET.

[60959.]—**Chuck.**—Would someone who has experience let me know which is the best kind of chuck for holding drills and studs up to 1in.? I have tried Cushman's, but the grip is weak, and it gets inaccurate when used some time.—J. P.

[60960.]—**Bearings Heating.**—I have a shaft, each end fits to wall box, and the centre to bracket shaft, is driven from one end, and from the centre drives a grindstone or buff as required; at other end also drives stone or buff. The centre bearings will get hotter than the hand can bear in less than an hour, whereas the outer ends remain cool after six or eight hours' works. The end which I should think has all the pull from engine does not get hot. I use sperm oil to lubricate as used for Otto. Length of shaft 13ft., dia. 1⅝, runs about 180 revs. There is a collar on shaft each side of centre bearing, I presume, to keep shaft in its place. Why are they placed there? Would not one collar at each end inside box bearings be better?—YOUNG CUTLER.

[60961.]—**Chemistry.**—Is there any sympathetic ink known which, after having been written, will be invisible when cold and a bright red or crimson when heated by a fire? Also an ink which will have the reverse effect to above in any colour—i.e., visible when cold and disappear on application of heat?—LETTER WRITER.

[60962.]—**Exhaust.**—What are the objections raised to exhausting steam into a brick chimney? Will it cause any serious injury to the brickwork through dampness, and if the exhaust pipe is put in the chimney, should the delivery end of pipe be highest?—STOKER.

[60963.]—**Terracotta.**—Is there any arrangement for burning articles, such as plates, vases, statuettes, busts, &c., modelled by an amateur in clay, into satisfactory terracotta in existence? It has struck me that there probably exists some sort of small kiln or furnace heated by gas. If so, I should be glad to have particulars.—ARCHITECT.

[We fancy Mr. J. J. Lish, the Vice-president of the Society of Architects, could give you some information. He is not a very distant neighbour, and has made many experiments with terracotta.—ED.]

[60964.]—**Rubber and Lead.**—I want to fasten vulcanised indiarubber on lead. I have three various kinds of cements, glues, &c. By the constant knocking of the stamp, the rubber comes off the lead. I have also roughed up the surface of them so that it would help it.—JAS. LOCKWOOD.

[60965.]—**Saxophone.**—Can any reader give me information about this instrument? I bought one, thinking the scale was like the clarionet, being similar in appearance to it, and blown with a clarionet reed, but I am unable to make anything of it. When overblown it sounds the octave above instead of the twelfth, as the clarionet does. It has two keys at top, apparently, to sound the overblown notes. Why two? Any information, especially the use of some keys that I can make nothing of, would be welcome. The instrument is of French make—Loisette and Quandieu, Valenciennes.—SAX.

[60966.]—**Accumulator.**—I have a 2-volt accumulator, which is out of order. I sent it back to the makers, but they informed me that they found it would retain its charge. It lit a small lamp after being charged by a dynamo; but the next morning the charge was vanished. Can anyone inform me where to look for the defect? I presume it cannot be short-circuited internally, or it would not light up at all. Perhaps the better plan would be to convert it into a De la Rue's battery. If so, will someone kindly give me full directions for making same? When this battery is exhausted, what salt of silver does the residue contain, and is it difficult to regain the metallic silver? I only want to use it occasionally to light a surgical lamp.—GRATEGOSH.

[60967.]—**Ferrous Oxalate Developer.**—I have heard of a method of revitalising used ferrous oxalate developer with, I think, tartaric acid. Will someone in the "know" kindly state what proportion to use, as I often use a half-pint only twice when enlarging?—GRATEGOSH.

[60968.]—**Bichromate Battery.**—I have an induction coil that gives 4in. sparks with 5 pint Bunsen cells, but wishing to avoid the use of nitric acid, and also the time lost in charging so many cells, I thought of constructing one large bichromate cell of the following size: Three carbons, 12in. by 6in., and two zincs between, also 12in. by 6in., the solution to be contained in a two-gallon jar. The questions I wish to know are: (1) Will one cell containing carbons and zincs of the size named work coil as well as two smaller ones containing carbons and zincs half the size? (2) Which is best to use in making solution—chromic acid or bichromate of potash?—J. W. J.

[60969.]—**Fulcrum.**—Would some kind mathematician give me dimensions of a malleable casting that would stand the strain of 30cwt., the casting to form a fulcrum? I want to insert a 2in. square hole in casting for stud to form fulcrum, I should think, 4in. from end, say; the lever would be of wood to the length of 8ft. from centre of fulcrum. Would the following dimensions be sufficiently strong enough, say size of casting 2ft. long, 1½in. thick, 3in. deep at ends, and 4½in. deep at the hole for fulcrum, and gradually reduce back to ends?—ONE IN THE DARK.

[60970.]—**Lathe Work.**—Would one of our kind friends state what is the usual rate of feed on an 8in. centre screw-cutting lathe, as I now travel saddle about 2ft. per hour? Also, please say what is a usual cut to take with roughing tool on a 1½in. or 2in. bar from 4ft. to 7ft. long, as I think it is rather slower and a lighter cut than is usually taken.—IRON TURNER.

[60971.]—**To Mr. Bottone or Mr. Eaves.**—I have one of Jones's shunt wound dynamos, 30c.p. It runs well with one lamp on. As soon as I put two on I can only get them red hot, and the engine runs away as though the belt had come off. As soon as I take one of the lamps off again, the engine seems to get its work again, and one lamp is fully lighted. The machine is nearly new. I run it six or seven hours every night with one lamp without any trouble. Any advice will greatly oblige—A THREE YEARS' SUBSCRIBER.

[60972.]—**Dewrance's Asbestos Packed Valves and Water Gauge.**—Could any of our readers give their experience in the use of Dewrance's asbestos packed valves and water gauges? Are they liable to leak or get out of order? If they do leak, do they require packing afresh, or can they be ground? Can a fitter repack them or put them to rights again?—S. C. W.

[60973.]—**Double Engine.**—Would any of the readers of the "E.M." tell me the power of a pair of engines 2in. bore, 3½ stroke, set at quarter stroke?—NOMINAL.

[60974.]—**Steering Apparatus.**—Would someone kindly give me any information as to the steering of torpedo boats? I mean the latest developments in the way of quick steering. I think there is something new within the last month or two. Also, are twin screws placed side by side?—OS.

[60975.]—**Paraffin Oil or Coal Gas.**—Information required respecting the paraffin oil gas-works now exhibiting at the Edinburgh Exhibition—mode of manufacture and the number of cubic feet of gas, and the cost per 1,000ft., which can be made from the various kinds of mineral oils now in the market. Which would be the cheaper and better gas for a village four miles distance from a railway station or coal depot—coal or oil gas?—JIMBO.

[60976.]—**Arithmetical Question.**—I wish to pay off a mortgage of £1,000 by ten equal annual instalments, the principal and each continuing balance carrying interest at 5 per cent. less tax of, say, 6d. in £. Will one of your readers show a simple way of arriving at exact amount of instalment required to extinguish principal and accruing interest by end of period? The only way I know of is by approximating amount of fixed instalment, and then experimenting to find exact sum required.—PUZZLED.

[60977.]—**Ventilation of Sewers.**—Would any reader kindly say what formula is generally employed in ascertaining the necessary amount of ventilation for sewers, and would he explain the formula by working an example?—SURVEYOR.

[60978.]—**Electric Lamp.**—TO MR. BOTTONE.—I have got one of the wonderful lamps from Messrs. Shippey Bros. It is labelled 12 volts, and should give 10 candle-power. I put twelve Fuller's cells on it, but could only get about 2-candle-power out of it. How many pint bichromates will it take, and how should they be coupled up?—DE BONNE FOI.

[60979.]—**Polishing in the Lathe.**—Will some of our experienced readers kindly tell me what tools are required for, and the method of, dressing the surface of ornamental brasswork in the lathe, such as gasfittings, &c.?—POL DOL.

[60980.]—**To Mr. Striffler.**—I want to light one 5c.p. lamp with the Daniell battery you mentioned in last week's "E.M." If you will tell me what size and how many calls I should want, and how long the battery would last without recharging, I shall be extremely obliged. Also what solution to use with the zinc, and if the zinc should be amalgamated.—ELECTRA.

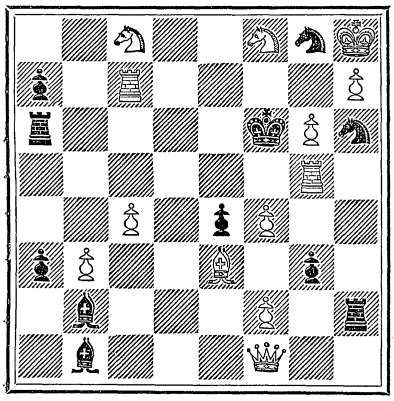
[60981.]—**Cracked Wheel.**—Have a corn-crushing machine with two crushing wheels, one 12in. diameter and one 3ft. diameter. The 3ft. wheel is cast iron, and by some accident is cracked through the main crushing-rim. The rim is about 1in. thick, 4in. wide. When first seen was only just visible, but is now open 1-16in. Would some kind reader of our most valuable paper say the best way to bring it together and keep it in place? Should it be made hot round to bring it up in place, and then riveted with straps under, or drill holes in the crack and put in studs?—FORCE PUMP.

CHESS.

ALL Communications for this department must be addressed to J. PIERCE, Langley House, Dorking.

PROBLEM MXVIII.—BY J. PIERCE.

Black.



White. [13 + 11

White to play and mate in three moves.

SOLUTION TO 1,016.

White.	*Black.*
1. P-Q 3.	1. Anything.
2. P-Q B 4	2. K or B moves.
3. P-Q Kt 5.	3. K moves (disc. mate).

NOTICES TO CORRESPONDENTS.

CORRECT solutions to 1,016, by G. A. A. Walker (very easy), A. Dean, A. Bolus (very simple problem), and F. Krassor; to 1,017, by Black Pawn (very neat and interesting).

J. THOMPSON should have been bracketed first with full marks in Tourney C.

R. PILKINGTON and E. F. Gerahty are thanked for games.

W. BIDDLE.—Thanks for the problem; it is neat, and seems quite sound.

A. TUPMAN.—You do not appear to have given Black his best defence. How if 1. $\frac{\quad}{\text{R-K 5}}$?

A. BEGINNER.—You have overlooked in 1,016 the defence 1. $\frac{\quad}{\text{K-K 5}}$ In 1,017, why not (after 1. $\frac{\quad}{\text{R-K 5}}$) 2. $\frac{\quad}{\text{B-Q 5}}$?

BLACK PAWN.—Thanks for inclosure. We have entered your name for the two Tourneys.

WE have pleasure in drawing attention to a new Chess Monthly, proposed to be started Jan. 1, 1887, styled the "Yorkshire Chess Magazine." It will consist of 16 pages, and will relate principally to the play and Chess news of the county which has always been distinguished for its Chess strength. There will also be a problem department.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, Nov. 17, and unacknowledged elsewhere:—

WATT, WINNALL, AND CO.—T. B. Etty.—H. Milnes.—Foster and Williams.—Gilford Mills Reading Society.—H. H. Holt.—J. F.—Grantham Crank Co.—G. Yule.—B.—T. W.—Acier.—J. H.—S. Bottone.—Brick.—H. S. H.—A Poor Sawyer.—Welsh Hog Hair.—Lumsie.—A. B. C.—A Student.—Nil.—Gerard Smith.—Blacksmith.—An Engineer.—Country Parson.—Workman.—Chemistiana.—Oldham Chap.—Retlaw.—Puzzled.

LEVER. (The reason could have been found in any cyclopædia. When a day is added every fourth year, the "year" is made a trifle too long (it is 365d. 5h. 48m. 50·4s.), and it was arranged to make what is known as the "Gregorian correction," that is, to omit three leap years in four centuries, the years chosen being those which terminate centuries in which the first pair of figures is not divisible by 4. Thus 1800 and 1900 were omitted from the list, but 2,000 will be a leap year.)—WILLIAM HEATH. (The letter you sent was received, and an answer was duly inserted on p. 184, third col., "Transfer," in which you were referred to a reply which appeared on p. 90, this volume.)—W. S. M. (See several articles and replies in back volumes, and procure the work noticed on p. 123, "Photo-Engraving and Photo-Lithography," by W. T. Wilkinson, Otley, Yorkshire. Unless you have a good deal of the work to do, it will pay better to "give it out.")—JAMES HUNTER. (Mastic varnish is generally used on oil paintings. It is made by dissolving mastic in turpentine.)—JENEVA. (How can anyone say without examining the two watches? There is a large quantity of low-priced rubbish in the market now; but as a rule price is an indication of the value.)—CANNOT HEAR. (Take the pipes away from the noise—that is the only remedy.)—W. R. (It is a question for the "Wanted" column of advertisements; but you will find some information in back volumes. As a matter of fact, any tough paper will answer.)—NOVICE. (What do you mean by "renaming a child"? Consult a lawyer. The question is of no interest to our readers.)—FENDER. (The best thing, perhaps, is to cover the parts with a thin smear of black lead and pure grease. When metals are plated and parts become uncovered, corrosion or rusting goes on apace. The only radical cure is to replate.)—R. C. B. (Consult the advertisements. Such a query is unsuitable; but we should think you would obtain what you require from any of the large stationers in Leeds.)—SCRIBENDUS. (Sufficient directions have been given over and over again in our columns; but Zaehnsdorf's "Art of Bookbinding" will help you.)—U. BEATON. (You will find a sketch of a coil-winder in No. 917, p. 166; but all that is necessary is a spindle having a crank attached to one end. The bobbin is placed on the spindle, and the latter mounted in movable bearings.)—TEKE-LI-LI. (The choice depends on local circumstances. There are plenty of gas-engines double the size you mention. See p. 145, No. 891.)—MALLEABLE IRON. (We can only refer you to the Directory.)—AN AMATEUR. (Do not understand what you mean by "japeing." If japanning, see indices of recent volumes.)—W. A. T. (It must be left in the acid for some time, and be well scoured with sand and washed. Then it is immersed in dipping acid until the colour is bright, when it is washed and dried off in hot sawdust. 2. Amber is a fossil mineralised resin, found in various beds, but it mostly comes from the Baltic shores of Germany.)—CALEB TILLEY. (Suppose you read some elementary work on astronomy before setting out to criticise. Your nine questions are answered, so far as they can be, in any elementary manual of astronomy. For the present it will be sufficient to say that the sun "as" a "rotarey" motion, but does not "revolve around an orbit"; it has an atmosphere. It is amusing to learn from you that Prof. G. H. Darwin's address to the British Association contains "some very grave errors connected with the theory of the universe.")—G. M. S. (No pamphlet on the subject; better take a few lessons from a laundryman if you cannot refer to back volumes. Put a little wax in the starch.)—A. STACEY. (Use tin-lined pipe, or see that only steam comes over. If either of these suggestions does not provide the remedy, try a glass retort.)—H. HARPER. (Yes, by unconscious—sometimes conscious—muscular movements of the operators. See indices for Table-turning.)—DRIVER. (Not that we are aware of; but there are friendly societies bearing such names all over the country.)—DUPLEX. (Answered many times; see indices. For nickel-plating, refer to Nos. 993, 994, 995. 2. Mr. Sprague's book on "Electricity" is published by E. and F. N. Spon, 125, Strand, W.C., price 15s. 3. Procure fresh solution when the old becomes dead; but recover any valuable metal which the latter may contain.)—AMATEUR, W. L. (Procure an iron box or piece of pipe, and imbed the screws and nuts in clippings of leather, filling up with animal charcoal dust. Lute the box air-tight with a lid or clay, and bring all to a soaking red heat for a couple of hours, say; then immerse the contents in water.)—LEROY. (It would be well to keep to one until he is old enough to discriminate between the two languages.)—W. P. (That query is suitable only for the advertisement columns. See Hints No. 4.)—AJAX. (For polishing black marble see p. 456, No. 1088.)—PLATO. (Todhunter's, Newth's, and others. Lower priced works are published by Collins and by Chambers. Perhaps Gregory's "Mathematics for Practical Men: Pure and Mixed Mathematics" would suit you. That is published by Lockwood and Co., Stationers' Hall-court, E.C., price a guinea.)—HARRISON. (Chavasse's "Advice to a Mother"; Day's "Treatise on the Diseases of Children"; Ellis's "Practical Manual of the Diseases of Children"; Goodhart's "Student's Guide to Diseases of Children," all published by J. and A. Churchill, New Burlington-street, W.)—J. M. C. (You mean an hydraulic motor. A simple one is to have two high-pressure taps (two-way) at each end. These are connected by a link, and the motion of the piston rod is made to "tap" that up and down. See catalogues of makers or indices of back volumes.)—T. C. SMITH. (The art of electrotyping is described in such books as "Watt's Electro-Metallurgy," published by Lockwood and Co." Stationers' Hall-court, E.C. It has been frequently described in back volumes, and unless you have power and a dynamo you can have electrotype blocks made for you much cheaper than you can do the work yourself. A mould is taken in gutta-percha or composition from an engraved wood-block or type, and a thin shell of copper is deposited on that by means of the electric current. The shell is then filled up with metal and mounted on wood. See p. 559 last volume, and the indices.)—R. W. (Several have already been given in recent volumes. See Nos. 1026, 1027, 1029, 1041, for a series of illustrated articles on electro-motors.)—AMATEUR. (The hardening of mill bills and picks has been described many times. No chemical at all is required, though many pretend to have some secret preparation. See pp. 152, 174, 196, Vol. XLI.)—E. S. MORLEY. (What are they to answer when you give no description? Why not apply to the designer?)—G. M. S. (It is known as Oleum aurantii, and consists to the extent of 95 per cent. of a terpene and of an oxygenated oil having the composition $C_{10}H_{16}O$. The terpene is known as hesperidene. Nothing remarkable in the fact that the oil ignites at once when a piece of orange peel is squeezed near a candle flame. Almost any oil would do that if thrown into a flame in drops so minute.)—A. L. (We do not know of any books on lacquering; but details have been given many times. You must clean and polish the metal, which is perhaps best done by scouring well and immersing in "dipping acid." Wash in hot water, dry off in hot sawdust, and apply the lacquer. The article must be quite as hot as can be conveniently held, and the brush should be a broad flat camel hair. Don't go over the same part twice. Lacquering is very simple, but requires a lot of practice to do it well.)—POLO. (It is essential to destroy the germs in the air and to exclude oxygen, both of which have no doubt an influence in breaking down animal tissues to the putrid state.)—AL. DE HYDE. (See indices, or No. 898, p. 313, No. 885, pp. 15, 16. 2. No instrument of the kind. You want an ammeter, a voltmeter, and a resistance instrument. 3. Rather too antiquated. It is simply a little electromotor, which drives a steel point through the paper, making a series of minute holes. The paper can then be used as a stencil for making copies of the writing.)—FREDERICK. (Kindly look through back volumes, or procure an elementary textbook.)—FRITZ. (Dissolve sealing wax in methylated alcohol, or make it at once by proceeding as if about to make sealing-wax, as described in No. 1073. 2. Brunswick black generally.)—CLOTH. (The nap is raised by means of "teazles," the heads of the teazle plant, which contain a number of very fine hooks.)—R. M. K. (1. Yes; a weekly tenancy makes no difference. 2. No, not until the Stock Exchange grants a quotation. Any stockbroker will buy or sell for you; but you had better exercise caution with regard to the numerous new companies which are just now being promoted. Not one in ten have the faintest chance of success.)—ARTHUR MEE. (They were received, but we could not spare space, and besides, the drawings really would not reproduce well—best thanks all the same.)—RACKRENT. (You had better pay the money. It will cost you more to defend the action, and the judge is quite as likely as not to allow the costs of the two writs after all.)—KITTY. (Yes.)—MISERY, M.M.I.SC.S., HARRISON. (In type.)

NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve Months, Post Free to any part of the United Kingdom. For the United States, 13s., or 3 dol. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office Order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. JAMES W. QUEEN and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII., XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX., XL., XLI., XLII., and XLIII., bound in cloth, 7s. each. Post free, 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post free from the office (except index numbers, which are 3d. each, or post free, 3½d.).

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XL., and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

CHARGES FOR ADVERTISING.

ADVERTISEMENTS in the SIXPENNY SALE COLUMN.

	s.	d.
Sixteen words	0	6
For every succeeding Eight words	0	6

*** It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions and in cases where the amount sent exceeds One Shilling, the Publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O.'s.

The address is included as part of the advertisement, and charged for.

Advertisements *must* reach the office by 1 p.m. on Wednesday, to insure insertion in the following Friday's number.

OUR EXCHANGE COLUMN.

The charge for Exchange Notices is 3d. for the first 24 words, and 3d. for every succeeding 8 words.

Good Value Offered (cash or instruments) for all kinds of sound or repairable Scientific Appliances.—CAPLATZI, Science Depot, Chenies-street, near British Museum. Established 1862.

Wanted, **Photo Apparatus**, wet or dry, cameras, sundries, &c., in exchange for Microscopic or Magic Lantern Slides.—Apply, PIGGOTT, Chemist, Huddersfield.

"English Mechanic," 500 numbers, from 593 to 1093, with indices, clean and perfect. What offers in exchange?—STUBBIN, Buckshorn Oak, Alton.

"Knight's Mechanical Dictionary," first 18 parts, quite new, cost 2s. each. Will exchange for Engineering Books, cash, or offers.—T. BATCHEN, Inness-street, Inverness.

"English Mechanic," Vols. XXXVII. and XXXVIII., for Microscopic Slides, stained or injected.—JONES, Duke-street, Settle.

Photographic.—Half-plate or larger lens wanted; will give 12in. plate electric machine, or small electro-motor, suitable for driving sewing machine.—B. D., 40, Sandbourne-road, Brockley, S.E.

Tricycle, Coventry lever, double steering, two track, adjustable pedals, cushioned seat, good condition, newly painted, Offers.—FORD, 75, St. Paul's-road, Camden, N.W.

Electric Bell, 4in., 3-cell battery in box, indicator 6 holes, 6 china pushes, 1 barrel push, all new. What offers?—M., 11, Victor-road, Holloway, London.

Steam Gauge, Bourdon's patent, equal new, 6in. dia. Exchange for smaller, or offers.—T. H., 5, Kingsley-street, Sunderland, Durham.

Unbound Vols. XIV. to XVII. **"Electrician"** for Sale, or Electrical Books accepted in exchange; back vols. "Electrical Review" preferred.—ELLIOT, Gennaro Serra, Naples.

What offers for complete **Parts of Six Tricycles,** rear steering, partly made, rims drilled, hubs drilled and tapped, 6 wheels made, all lugs brazed on, cranks finished; when completed eminently suitable for hiring out; good winter occupation ready for next season. Wanted, one horse-power Gas Engine, suitable for dynamo. Other offers requested.—BLACKFORD, Machinist, Windsor.

What offers for good 5-keyed **Piccolo**? Small Slide Valve Engine or Electro-Motor preferred.—A. PAYNE, 36, Brunswick-street, High Town, Luton.

Steam Engine, powerful one-horse, Washing and Wringing Machine combined, Hand Sewing Machine, small Boiler on wheels, Shop Stove. Exchange.—MILLER, 1, Melbourne-square Brixton-road, S.W.

Camera, Lancaster's ¼-plate Instantograph, complete, only been in use three months, 6 dark slides. What offers?—LAING, Bridge of Earn, N.B.

Saw Bench, planed iron beds and frame, rising and falling spindle, 36in. saw, band saw attachment, nearly new, first-class order, for good Screw-cutting Lathe, or good Piano, or offers.—NEWMAN, Mill, Stanstead, Essex.

Splendid **Cardboard Model** of Buckingham Palace, in glass case. What offers in exchange? Anything useful.—W. C., 49, Mill-lane, Leicester.

Kelly **Orchestral Harmonium,** 21 stops, walnut, 6 rows, percussion, cost 68 guineas. Want small Gas Engine and Dynamo.—INWOOD, 74, Chestnut-avenue, Forest Gate.

Lathe, back motion, expanding chuck, 10in. centres, slide-rest, no bed; for Vertical Engine and Boiler, 3 H.P.—WM. SKINNER, 26, High-street, Elgin, Scotland, N.B.

"Comparative Anatomy," by Gegenbaur, 8vo., 645 pages (Macmillan), bought three months ago by mistake, never used. Offers.—A. MITCHELL, Sutton-on-Hull.

Wanted 1 or 2-man **Gas Engine.** Will exchange a Cruiser Tricycle (makers, Hillman, Herbert, and Cooper), in first-class order, cost last year £22 nett.—GREENWOOD, 76, Manchester-road, Rochdale.

Lathes.—Turning, Polishing, Scratchbrushing, Tools, and chucks, cheap. Giving up business.—CATON, 60, Ludgate-hill. Third floor.

Stamping Press, with chucks and dies, also Dynamo, cheap. Giving up business.—CATON, 60, Ludgate-hill. Third floor.

Wanted, 2½ or 3 H.P. Vertical **Engine and Boiler** combined, in good working order, cheap. Exchange Black Oats, mixed, few white, and some cash.—H. ROGERS, Bassett's Farm, Mayfield, Sussex.

Flute, Blackman's patent, 4 keys, German silver mounts, cost 15s., nearly new. Joiner's tools or offers.—R., 22, Marlborough-road, Dublin.

Exchange 36 numbers **"English Mechanic,"** for ½lb. No. 24 Silk-covered Copper Wire, or offers.—PRITCHARD, 5, Sloan-street, Lisburn, Co. Antrim, Ireland.

Wanted, **Magic Lantern,** 3½ or 4in. condenser. Exchange 4in. centre Lathe, 3-speed wheel.—HOULT, 28, Westville-road, Shepherd's Bush, London, W.

Old **Watch and Clock Works,** suitable for experiment. Exchange small Printing Press and Type.—ROBERTS, 50, Menzie-street, Liverpool.

"English Mechanic," 5 Vols., Nos. XXXVII. to XLI., inclusive, for sale or exchange. Should like Mr. J. T. Sprague's "Electricity," latest edition.—J. GRAY, 10, Pancras-road, N.

A 10-stop Pipe **Finger Organ** for an American Organ. Space required.—Address, EXCHANGE, No. 83, Stanhope-street, Newcastle.

"English Mechanic," to date, 44th volume, complete and clean. Offers in scientific articles.—Address as above.

Wanted, small **Rolling Press,** suitable for zinco-transfers. Offers.—BEAVEN, Warminster.

Wanted, small **Litho. Press,** suitable for amateur. Exchange Lenses, &c.—BEAVEN, Warminster.

Wanted, a really well made Model Vertical **Engine** and BOILER, about 1in. stroke, for good scientific exchange.—W. S. HOW, 75, Great Portland-street, London.

50 **Microscope Slides** in exchange for small Printing Press, Unmounted Objects, or anything useful.—P. LINTIN, 170, Freedom-road, Walkley, Sheffield.

Model **Vertical Engine,** cylinder 2¼in. by 1½in. Would take a Slide-rest, or anything useful for a 2½ centre lathe.—W. MARTIN, 25, Willow-grove, Plaistow, Essex.

New double **Vertical Engine,** 2 cylinders, 2in. bore, 3½ stroke, suitable for boat or anything. Exchange for good Telescope. Stamp for particulars.—SEDGLEY, 22, Ryding-square, West Bromwich.

Electro-Platers.—Brass Moulds for casting Britannia-metal Cruet, handle, feet, supports, weight 30lb. Samples sent. Exchange for Gramme Armature (Dynamo Castings, Xero), value 70s.—HEMMING, 165, George-street West, Hockley, Birmingham.

Tricycle, nearly new, part exchange; also 50in. Bicycle, nearly new, Bown's ball bearings, cowhorn handle bars.—F. GRIFFITHS, Wednesfield Heath.

Chaff Machine for hand or steam power, by Bentall, good condition; also Oat Crusher, nearly new, by Bentall, for hand or steam. Offered exchange, anything useful.—F. GRIFFITHS, Wednesfield Heath.

6-ton **Weighing Machine,** in good condition, lever 4ft. long, part cash and exchange.—F. GRIFFITH, Heath Town, Wolverhampton.

54in. "Fleet" **Bicycle,** ball bearings throughout, latest improvements and accessories, new last season, cost 19 guineas. Exchange for 1½ H.P. Engine.—W. J. CROFT, Highclere, Marlborough-road, Merton.

Large tourist **Telescope,** Bottle Jack, Hand Sewing Machine, good condition, for small Lathe Heads, Bar Lathe, or offers.—A. T. INSKIP, Shefford, Beds.

Wanted, good half-plate **Camera Lens,** Lancaster's Instantograph preferred. Good 2½in. centre Clockmaker's Bench Lathe in exchange.—HEWETT, 14, Melson-street, Luton.

Wanted, a small **Plating Dynamo** in exchange for Assay Balance and a Fletcher Crucible Furnace, Vice, Water Still and Condenser, or Field Glass.—Address, W. C. REID, 7, Graingerville, Newcastle-on-Tyne.

"English Mechanic," Vols. XXXIX. to XLV., unbound, clean, 4 Nos. short, also ditto for years '71-2, bound, '71 incomplete. Take anything useful, optical line or offers.—Address, R GIBSON, 3, Gulistan-terrace, Rathmines, Dublin.

Bichromate Battery, Dressing Case. Exchange for Lathe Heads, Rest, Wheel, Crank, and few Tools or offers.—7, Russell-street, North Shields.

Electric Motor and an Edison Electric Pen for exchange. Offers invited. Value 15s. and 42s. respectively.—BRAUN, 1, Kilburn-square, N.W.

Exchange Howe's 6-guinea treadle lockstitch **Sewing** MACHINE, very little used, and part cash, for Lathe or Piano.—T STEVENS, 4, Princes-street, Clerkenwell.

Magic Lantern, 8ft. discs, 24 coloured 3¼ slides, in grooved box, screen, aphengoscope. Wanted, "Bottone's Dynamo," "Watts' Electro-deposition," "Hospitalier's Domestic Electricity," Sprague's, &c.—Above.

Copper Boiler, 18in. long, 9¼in. diameter, with flue through, working pressure 40lb. What offers?—A. B. WALKER, 245, Kensington-street, Girlington, Bradford, Yorkshire.

Wanted, **Launch Boiler,** Engine, Propeller, &c., for 16 by 5ft. boat. Can offer lot new Hammers, Axes, Planes, Ironmongery, Cutlery, &c.—HARRISON, Devoran, Cornwall.

Sausage or Mincing Machine. Exchange Medical Coil in good order. 5s. in value.—ROBERT HUGGARD, No. 2, Peter's-row, Dublin.

Wanted, good portable bellows **Camera** and Lens. Exchange first-class 20 candle-power Dynamo, in perfect working order.—LOWE, 11, Wills-street, Lozells, Birmingham.

Portable Billiards, full-sized ivory balls; Medical Coil and Battery, Electrical Machine, Silver Watch. Offers.—A. PERCY SMITH, Rugby.

Will exchange 48in. **Bicycle,** cost £10 of few months, for 3½in. centre back-geared Lathe and Slide-rest.—W. A. COBB, Diss.

Exchange **Gold Albert,** cost 4 guineas, for 1½ H.P. Boiler.—J. B., Post Office, Muirkirk.

"English Mechanic," 280 numbers, for Magic Lantern, Telescope, or offers.—Address, H. O. W., 17, Penford-street, S.E., London.

48in. **Bicycle,** Æolus balls, cone back, coil spring, cost 150s., quite new, splendid machine. Part exchange, anything useful. Camera, &c.—LEONARD WRIGHT, Hall-street, Willenhall.

Wanted, **Microscope** and Accessories, second-hand, by good maker, in exchange for Dynamo to light two 5 c.-p. lamps, or Electro-Motor to drive heavy sewing machine, &c. If microscope in thorough working order, would exchange both before-mentioned machines and a smaller motor for it.—A. W. MORGAN, 7, Railway-street, Chatham.

Look here!—Pair of Irish's Loud-speaking **Tele-**PHONES, new; 4 hole Electric Indicator, good; new 4-stop Pipe Organ, nearly finished; C.-D. V. Embossing Press; Gem Camera, 12 Lenses, good; Victrix Camera, 2 lenses, good; 12 by 10 View Lens, good; Cabinet View Lens, good; Set of Bagpipes; several large Photographic Porcelain Dishes; 8-day English Case Clock, splendid case; several hundred Negatives. All must be cleared out. What offers?—CLARK, Photographer, Spennymoor.

Youths' **Tricycles,** Meteor pattern, 3 machines, part finished; 1 cwt. loose fitting. Exchange good Lever Watch, offers.—Letters to W. SMITH, Bilston-road, Wolverhampton.

Sliding Resistance Box, Galvanometer, cost £9. Offers in Ruby Lamp, scales, 1-1 W. A. Landscape Lens, to value £3.—194a, Mare-street, Hackney, E.

Model **Boiler,** 10⅜ long, 6½ wide, all copper, tubular, Locomotive shape, with internal firebox, safety valve, taps, &c. Offers in exchange.—H. BUDD, Stoke-road, Gosport.

Mathematical Instruments.—Wanted, a thoroughly good set, in exchange for a first-class capped English Horizontal Watch, in good condition, cost £7; mutual approval—Below.

Ship's **Telescope,** worth 25s., offered for good Violin, with case and bow, or offers. Approval.—R. MILNE, 13, Observatory-road, Redhill, Surrey.

Pair best 10½ **Acme Skates,** half set Joiner's Hollows and Rounds. Exchange either for Cylinder Casting above 3in. bore.—H. L. See Sale Column.

Wanted, 120c.p. **Gramme Dynamo** and Arc Lamp. Exchange for 30 c.p. Laminated Armature and Incandescent Lamp.—A. POOL, Chipstaple, Taunton, Somerset.

Several new **Gas Bags,** to hold 6, 8, and 10 cubic feet, also some 6 and 8in. Lenses. Exchange for jewellery and part cash.—F. SWIGG, 159, Drummond-road, Bermondsey, London.

Leading Screw and **Change Wheels,** suitable for 5in. Lathe, and set suitable for 7in., in exchange for anything useful.—R. SMITH, Fazackerley-street, Chorley.

Blocks and Rope, three sheave, 1¼ rope, very good condition. Exchange good Opera-glass or offers.—R. SMITH, Fazackerley-street, Chorley.

"Ure's Dictionary of Chemistry," with plates, What offers? (or "Electrics.") Requires rebinding.—C. TARR, 5, Providence-place, Ayliffe-street, New Kent-road, London.

What offers in exchange for 18in. plate **Electrical** MACHINE, lock-up mahogany case; also 4½in. compound slide-rest; singly, or together; lantern, microscope, or photo apparatus preferred.—VARDEN, Boundary-road, Notting-hill.

Exchange Thomas's Lockstitch Treadle **Sewing** MACHINE, in good order, for lathe, model engine, or 50in. bicycle.—MARTIN, 45, Brunswick-road, Gravesend, Kent.

Fine 12 by 10 **Double Dark Slide,** fitted complete with focus and reversing frames, ready for fitting up camera. Offers.—See below.

44in. **Bicycle,** bent handle bar, by Davies and Co. Offers.—W. SAUNDERS, Dickleburgh, Scole.

Wanted, **Lathe,** 3in. centre, 3ft. bed, cheap, or exchange dynamo, motor, and batteries.—CHARCOAL WORKS, Hodson-street, Liverpool.

Six candle-power **Dynamo,** on mahogany base, also two Electromotors, 6 powerful Batteries (constant), and several Incandescent Lamps. Offers.—Address above.

Don't fail to find it.—See "Hope for the Unemployed," Sale Col., this issue.

THE SIXPENNY SALE COLUMN.

Advertisements are inserted in this column at the rate of 6d. for the first 16 words, and 6d. for every succeeding 8 words.

Economic Cookery.—Patent Heat Conductors for roasting, 2s. 6d.; baking, 2s. 3d.; boiling, 2s. per pair, carriage paid. See ENGLISH MECHANIC, Oct. 15, 1886, page 147.

The Patent Heat Conductors save a family pounds a year.—Agent, TALLACK, 28, Hatton-garden, London.

New Illustrated Price List of **Screws, Bolts, and** NUTS for Model Work, drawn to actual size, sent on receipt of stamp.—MORRIS COHEN, 132, Kirkgate, Leeds.

Fretwork.—Catalogue of every requisite, with 600 illustrations, free for 6 stamps.—HARGER BROS., Settle, Yorks.

Wimshurst Influence Machine.—Sole manufacturers of new and improved pattern. 12in. from 30s.—KING MENDHAM, and Co., Bristol.

Deposition of Smoke.—Complete Apparatus to perform this never failing experiment, with static electricity, 5s. 6d and 10s. 6d.—As above.

Standard Ohm, in boxwood cylinder, guaranteed correct to ten thousandth of ohm, 18s. 6d., with copper poles, 21s.—As above.

Galvanometer Cards for tangent and ordinary combined, vertical, astatic, reflecting, and unmounted compass cards.—As above.

Variable Resistance Incandescent Lamp STAND, invaluable for battery power, vide ENGLISH MECHANIC, Oct. 16, 1885, price 3s. 6d.—As above.

AND WORLD OF SCIENCE AND ART.
FRIDAY, NOVEMBER 26, 1886.

HAND-PLANING MACHINE CONSTRUCTION.

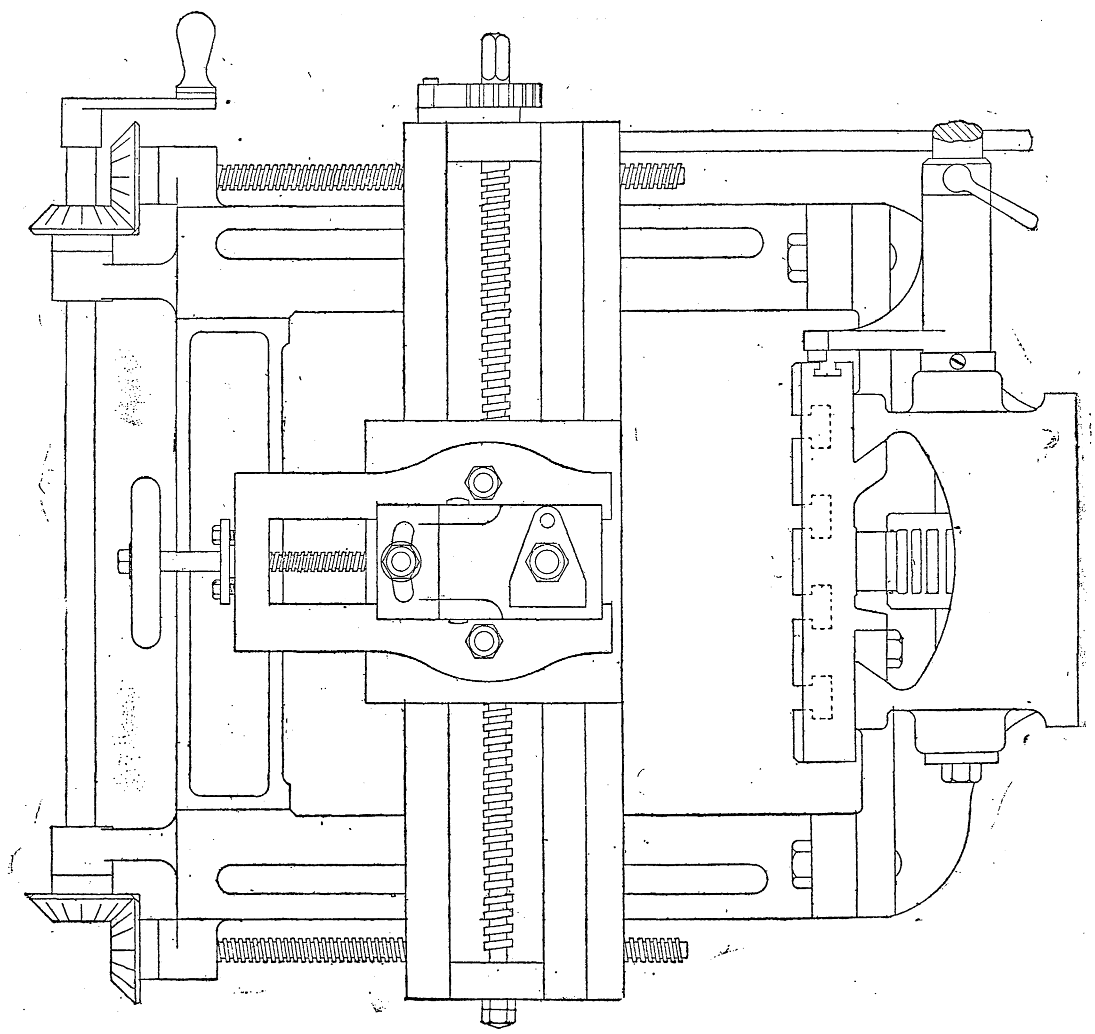
THE machine illustrated by accompanying engravings is capable of planing any object within the following dimensions :—30in. long. 13in. wide, and 12in. deep. A rectangular block of iron of those dimensions could be operated upon in the machine. The illustrations show three views: side, end, and top of the machine drawn to scale. In each view there is some slight modification in arrangement of the parts to better show the details of construction. In the side view, the screws for elevating the cross slide and the cross spindle with their mitre wheels, are removed. The central casting, which unites the four arms of the handle, is removed, but shown apart. One arm of the handle is drawn exactly in the position it would occupy if the central cross-piece were on the main spindle. In the end view the projecting part of the main spindle, and with it the handle, are not shown; the spindle is drawn broken off to economise space. In other respects this view is complete, and the dimensions of many parts may be got from it by measurement. The top view has all the cross slide and its belongings, including the mitre wheels, removed so that the dimensions of the bed, the table, and the standards may be clearly shown.

The general construction of the machine may be inferred from a brief description of its parts. The bed is a rectangular frame, 33in. long, 8in. wide, and 6in. deep, somewhat like a box without top and bottom; end and side views of it are given. The frame is braced together by three cross stays, which divide the box into four compartments. The sides have a strengthening bead along the bottom; the tops have the dovetail ways, which carry the table. Brackets to carry the upright standards are cast on the sides as shown. There are also bosses, one on each side, near the middle of the bed, to form the bearings for the main spindle.

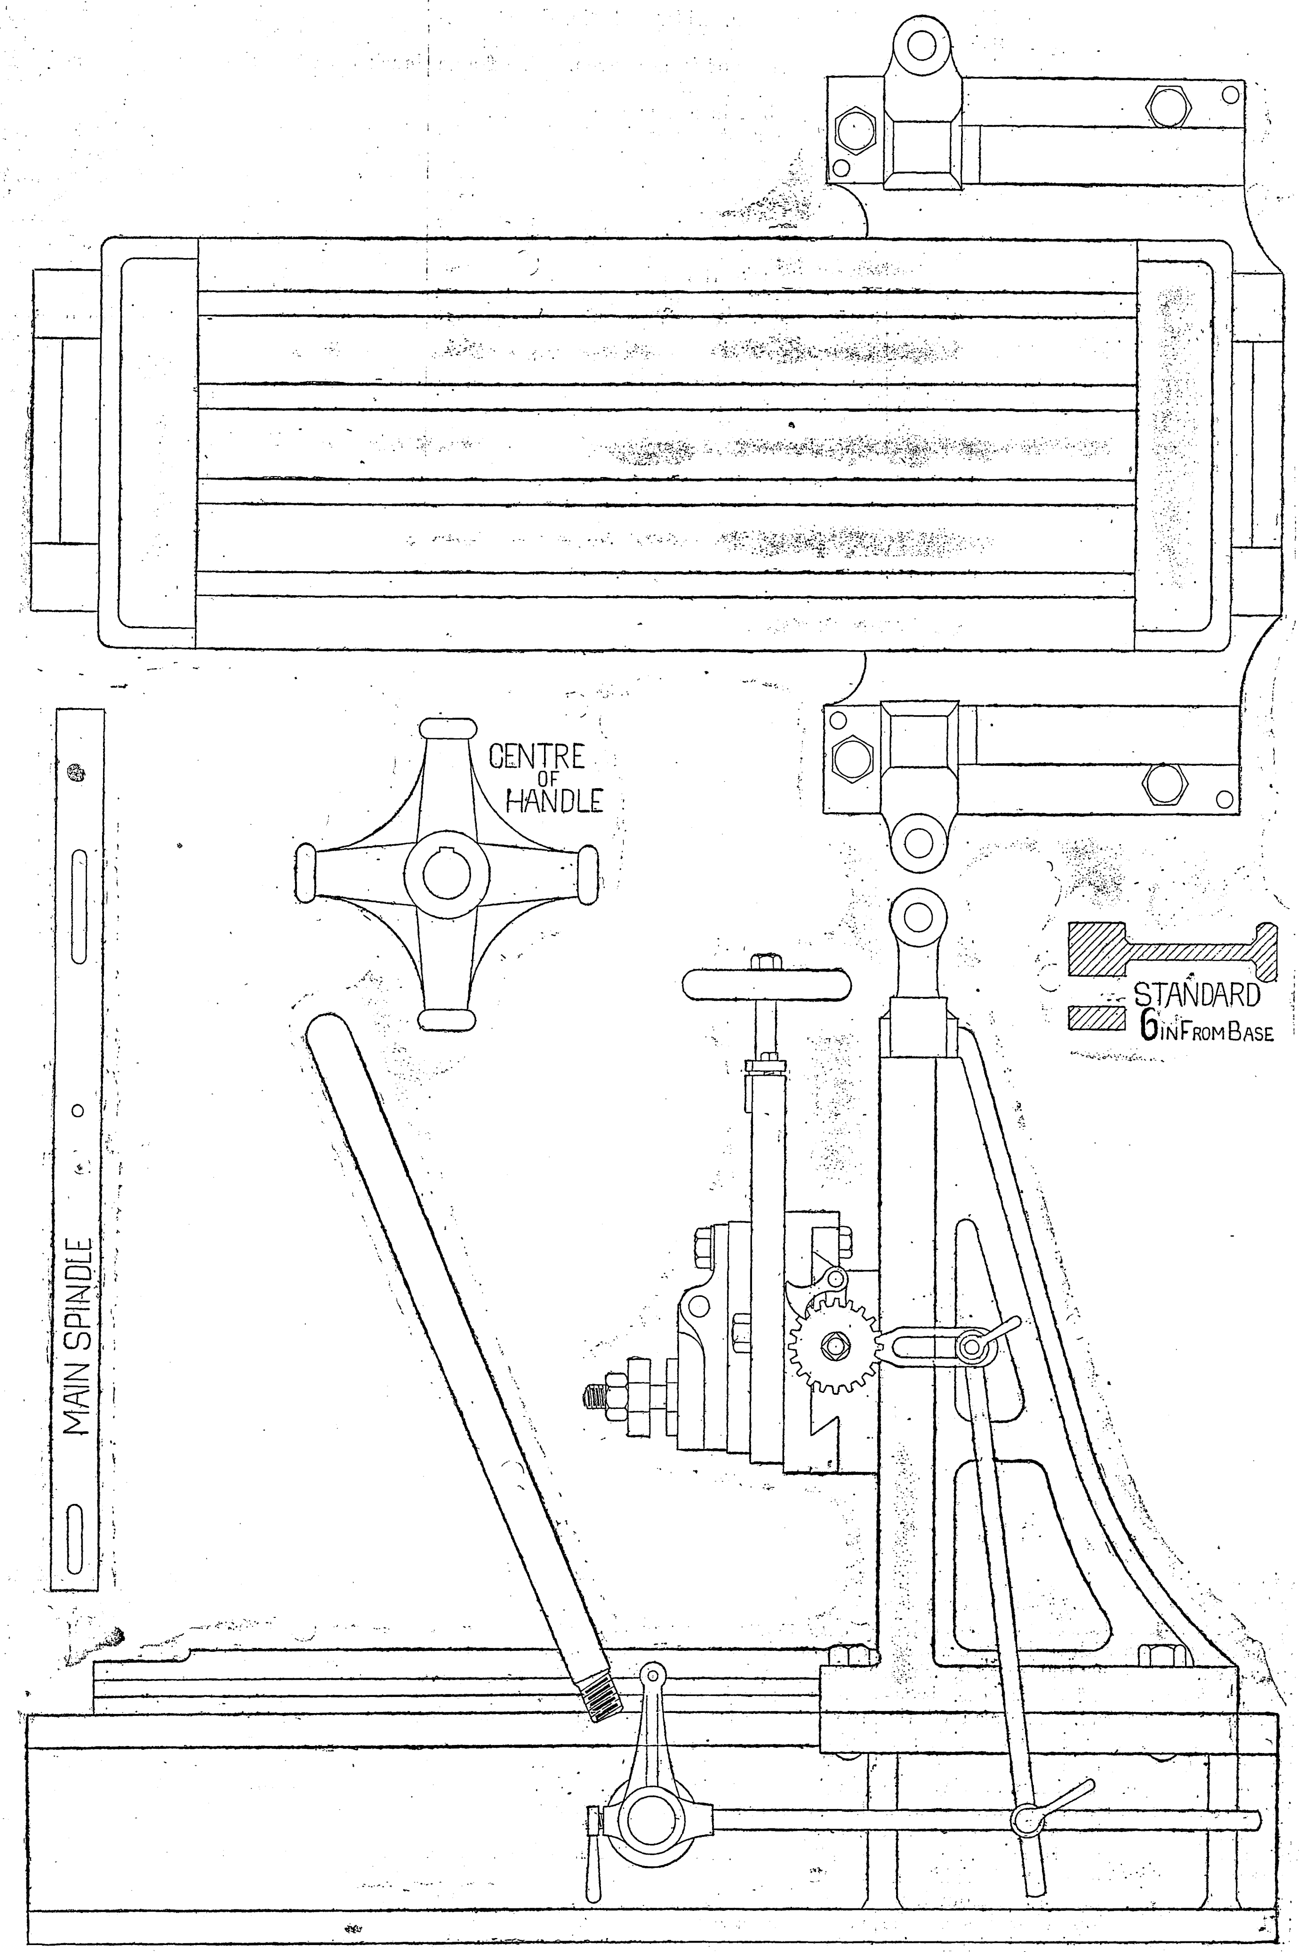
The table which slides on the bed is 30in. long, having 25in. of its middle part planed on the top and grooved with four ⊥ slots. To this part any work is fixed for planing. The parts at the ends beyond the planed part form trays to catch the chips planed from the work. The shape of the table may be seen on reference to the front view. It is fitted to slide on the bed, and has the loose strip fixed with six $\frac{3}{8}$in. bolts; the head of one of these is shown. The rack is fixed along the middle of the table by three screws. This rack projects $\frac{1}{2}$in. beyond each end of the table, so as to allow the pinion on the main spindle to traverse the table its full length.

The main spindle, shown apart, is simply a rod of mild steel, $1\frac{1}{4}$in. diam. and 22in. long, having a keyway sunk where the pinion comes, and another at the end where the handle comes. The other end has a hole, tapped to take a $\frac{3}{8}$in. bolt. The small circle near the middle of the spindle shows the position of a countersink, which takes the point of a grub screw, fixing the collar shown in the front view. The handle for the main spindle is made by screwing four rods into the central casting, which is shown apart in the side view, and so forming a cross, the four arms of which stand out 22in. from the centre.

The two standards that support the cross-slide are each fixed by two $\frac{5}{8}$in. bolts to the brackets cast on the frame of the bed. The shape of the standards will be seen by the front and side views, also by the sectional view shown apart. The two standards form a pair right and left—that is to say, they are not cast from the same pattern, but are reversed: the front and top views show this. The height, from the base to the centre of the cross spindle, is $20\frac{1}{2}$in.; the planed parts against which the cross slide fixes are 17in. long and $2\frac{3}{4}$in. wide, including the space for the bolt. The two standards are braced together at the top by a cross-bar fixed with bolts. Bosses, to form bearings for the axes of the mitre wheels, are shown cast on in convenient positions.



The cross slide is 23in. long, and may be moved vertically by the two square-threaded screws shown in the front view just beyond each standard. It is clamped at any required height against the standards by nuts at the back. The saddle sliding on this main slide is a plate $7\frac{1}{2}$in. by 7in., having a large hole in the centre to take the back of the fiddle-piece, which swivels upon this saddle, and is fixed at any angle by the two nuts shown in the front view. The fiddle-piece is 10in. long, and has a piece sliding vertically, moved by the left-handed screw and the handwheel shown. On the face of this sliding piece is fixed the cradle, in which what is usually called the tool-box swings; tool-box in this case being, perhaps, hardly the correct term to apply, as this machine is fitted with a tool-holder of the style known as Prof. Willis's. The cradle has a slight angular motion to allow of its adjustment when planing sides, so that the tool lifts clear of the work. The segmental slot in the front view shows this.



The tool-holder has for its base a plate, swinging on the cross-pin shown in both front and side views, and allows a tool to be clamped in any position to suit the work. This is such a great advantage over the confining limits of the usual tool-box that the latter is condemned by most people when the facilities afforded by the tool-holder shown on this machine are really understood.

The self-acting motion to the cross-slide, shown chiefly in the side view, a detail missed in the foregoing general description, remains to be noticed. The leading screw has fixed to it, by a cross pin, a wheel of 20 teeth; on

the boss of this wheel, and between it and the slide is fitted a two-armed flat piece, having a reversible pawl attached to its short vertical arm, and a light rod 15in. long attached to its longer horizontal arm. The lower part of the rod is attached by a swivel coupling to another rod centred on the main spindle and shown in a horizontal position. The motion for this arrangement is derived from a sliding bar on the edge of the table. This bar may be fixed at any desired place, and it rides over the upright arm of the cannon on the main spindle. This cannon has the end of the horizontal bar clamped to it by the screw shown; consequently, any motion of the upright arm is communicated, increased in amount, to the upright rod, and so moves the arm carrying the pawl. This moves the wheel and screw of the cross-slide, and as much as half a turn of the cross-screw can be got at a time by suitable arrangement of the levers. The complication of adjustments at the various joints may be all done away with by making the arm on the cannon adjustable; so all the joints and levers might be incapable of alteration without affecting the machine, provided that the horizontal and the vertical arms of the cannon could be adjusted angularly.

Having got the general construction of the machine illustrated and described, and its principal dimensions enumerated, an account of how the machine was made, involving, of course, some description of its details, are deferred for another article.

The accompanying illustrations, printed exactly one-fifth full size, may be carefully studied meanwhile.

ASTRONOMICAL NOTES FOR DECEMBER, 1886.

The method of finding the Sidereal Time at Local Mean Noon at any other Station will be found on p. 353 of Vol. XLII.

Spots and faculæ in greatly diminished numbers may still be seen at distant intervals on the sun's disc.

At 9 p.m. on December 21st the Sun is technically said to enter Capricornus, and Winter is supposed to commence. It is the so-called "Sign," however, and not the constellation, which he enters, as at the instant specified he is at the right angle of a rudely right-angled triangle which he forms with λ and μ Sagittarii.

This is the shortest day, as the Sun is only above the horizon in London for 7h. 44m., and is, of course, 16 hours and 16 minutes below it.

The Moon

Enters her First Quarter at 2h. 25·0m. in the afternoon of the 3rd, and is Full at 9h. 30·2m. a.m. on the 11th. She will enter her Last Quarter at 6h. 39·1m. in the early morning of the 18th, and be New at 9h. 54·7m. a.m. on the 25th.

Mercury

Is for all practical purposes a Morning Star throughout December, as he comes into inferior conjunction with the Sun at Noon on the 3rd. He attains his greatest elongation West of the Sun (21° 52′) at 2 p.m. on the 22nd; but he is very badly placed for the observer during the entire month. His angular diameter diminishes from 9·8″ on Dec. 1st to 5·6″ by the end of the year.

Day of Month.	Right Ascension.	Declination South.	Souths.
	h. m.	° ′	h. m.
1	16 50·9	21 50·6	0 9·8 p.m.
6	16 23·8	19 26·9	11 23·2 a.m.
11	16 8·4	18 7·1	10 48·1 „
16	16 10·4	18 18·1	10 30·5 „
21	16 25·2	19 25·0	10 25·6 „
26	16 47·7	20 50·2	10 28·3 „
31	17 14·7	22 10·3	10 35·6 „

The pendulum-like path indicated by the above Ephemeris commences in Ophiuchus, extends into the narrow northern strip of Scorpio, and returns to the Constellation in which it began. Mercury will be in conjunction with Venus at 1 p.m. on the 3rd.

Neither

Mars

Nor

Jupiter

will, for the purposes of the ordinary amateur observer, be again visible this year.

Venus

Is a Morning Star at the beginning of December; but at 5 a.m. on the 3rd she comes into superior conjunction with the Sun, and, subsequently, Souths after him. Even towards the end of the month, though, she only presents a tiny circular disc of 9·8″ in diameter, and from her great Southern Declination is miserably placed for the observer.

Day of Month.	Right Ascension.	Declination South.	Souths.
	h. m.	° ′	h. m.
1	16 28·6	21 36·2	11 47·6 a.m.
6	16 50·1	22 27·1	11 54·7 „
11	17 22·6	23 23·2	0 2·1 p.m.
16	17 50·1	23 50·5	0 9·9 „
21	18 17·6	23 59·2	0 17·7 „
26	18 45·2	23 49·4	0 25·5 „
31	19 12·6	23 21·1	0 33·2 „

As in the case of Mercury, the path of Venus this month begins in Ophiuchus, but it is described directly, or in the order of the Signs, and so extends into Sagittarius, where the planet will be found when the year terminates. On the 10th she is rather more than 1° North of θ Ophiuchi, and on the 22nd about 1½° North of λ Sagittarii. Neither of these stars, however, is visible under the circumstances. The conjunction of Venus with Mercury at 1 p.m. on the 3rd has been referred to above.

Uranus,

Continues invisible for the purposes of the ordinary observer; but

Neptune

May be seen, practically, all night long.

Day of Month.	Right Ascension.	Declination North.	Souths.
	h. m.	° ′	h. m.
1	3 36·7	17 33·5	10 53·8 p.m.
6	3 36·1	17 31·7	10 33·6 „
11	3 35·6	17 30·0	10 13·4 „
16	3 35·1	17 28·5	9 53·3 „
21	3 34·6	17 27·0	9 33·2 „
26	3 34·2	17 25·7	9 13·0 „
31	3 33·8	17 24·6	8 53·0 „

This retrograde path lies to the south, and very slightly to the west, of the Pleiades, in a very blank region in Taurus.

Saturn

Although, in so far as his Southing is concerned, he is a Morning Star, yet is fairly visible during the major part of the working hours of the night. His angular equatorial diameter increases quite insensibly from 18″ on December 1st, to 18·4″ by the 31st of the month. His ring system, as we remarked last month (p. 187), is slightly less open than it was last year, although this makes little or no difference in the amount of detail perceptible.

Day of Month.	Right Ascension.	Declination North.	Souths.
	h. m.	° ′	h. m.
1	7 34·1	21 26·9	2 54·7 a.m.
6	7 33·2	21 29·2	2 33·9 „
11	7 31·9	21 32·5	2 13·0 „
16	7 30·5	21 36·0	1 52·0 „
21	7 29·0	21 39·7	1 30·8 „
26	7 27·4	21 43·5	1 9·6 „
31	7 25·4	21 48·3	12 44·0 p.m.

Hence it will be seen that Saturn is travelling towards δ Geminorum.

Shooting Stars

May be watched for, with the greatest probability of success, from the 11th to the 13th inclusive, and again on the 24th.

Greenwich Mean Time of Southing of Seventeen of the Principal Fixed Stars on the Night of December 1st, 1886.

The method of finding the Greenwich Mean Time of Southing of either of the Stars in the above list for any other night in December; as also that of determining the local instant of its Transit at any other station, will be found on p. 355 of Vol. XLII. It must, though, be noted that the rules there given are not rigidly accurate when applied to Polaris, or any other close circumpolar star; though they will probably be found quite sufficiently so in practice.

PROF. S. P. THOMPSON'S IMPROVED DYNAMO.

About four years ago Prof. S. P. Thompson obtained a patent for improvements in connection with simple dynamo-electric machines, in which the field-magnet is in one piece without joint. A short time back he obtained another patent (No. 7860, 1886), which embodies some improvements in the armature, the object being the obtaining of a more efficient machine, having greater electrical output in proportion to its size and cost, less liable to wasteful heating in the electro-magnets or in the polar surfaces thereof, and having in general better magnetic and electric conductivity. Prof. Thompson prefers to employ a single core to receive the field-magnet coil, and makes the core shorter and thicker in proportion than in the older form of machine. He also prefers, for convenience of winding, to make it straight rather than arched. The core which receives the coil may be made in one with the pole pieces by casting or otherwise, or it may be of wrought iron, the pole pieces being cast upon it, or screwed or riveted to it. The field-magnet itself serves as a framework for the machine, and its pole pieces or either of them may constitute the bed-plate of the machine, the magnets themselves being of great solidity and mechanical strength, and presenting the advantage of a magnetic structure without joints. The field-magnets may be wound and excited in any of the ways known in the construction of dynamo machines, the coils being joined either in series with or as a shunt to the external circuit, or they may be separately excited, or they may be excited in any combination of these ways according to the circumstances in which the machine is to be used.

Fig. 1 and Fig. 2 illustrate the two ways of

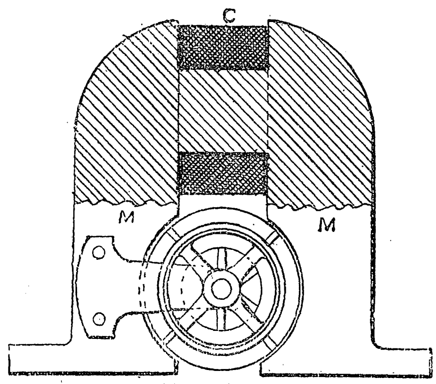

FIG. 1.

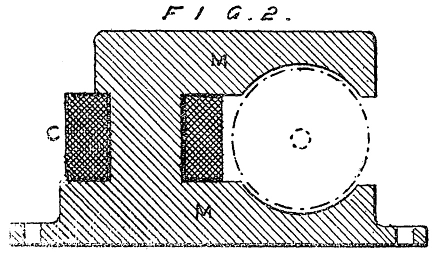
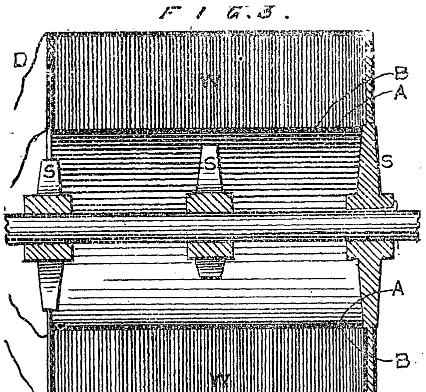
FIG. 2.



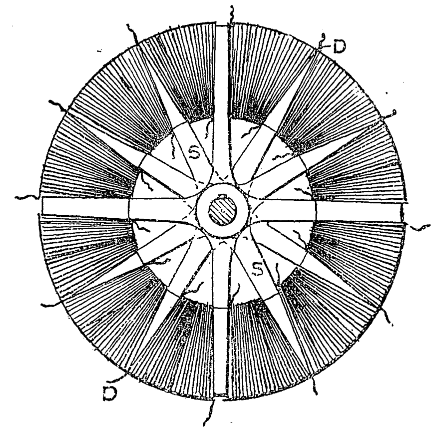
forming the field-magnets of the improved machine, the magnets themselves M M being of great solidity, having great mechanical strength, and possessing the advantage of a magnetic structure without joint. The coils are shown in position at C C. The armature is constructed upon spiders of suitable material, such as a non-

FIG. 3.



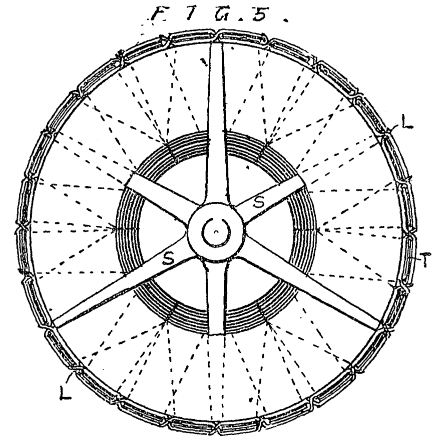
magnetic metal, keyed, or otherwise suitably fixed upon the driving-shaft, the spiders being formed with shoulders to receive and support a thin supporting cylinder or mantel, preferably made of thin sheet iron, well insulated from the spiders. The cylinder or mantel may be of some strong insulating material, such as hard vulcanised fibre or dermatine. There may be one or more such cylinders or mantels, each being borne at its ends upon the shoulders of a spider. The cylinders or mantels support and keep in place a number of thin iron washers, which are either plain or toothed externally. The process of construction of the armature frame and core consists in fixing one spider on the shaft by its key or other convenient and suitable mechanical means, then placing upon it one of the cylinders or mantles, then outside this the washers to a suitable number, preferably insulated from one another by sheets of varnished or paraffined paper, or asbestos, or other non-conducting material; then the next spider is fixed in position on the shaft, thereby securing the cylinder and washers in their proper places, and so on until the requisite number has been provided. Instead of washers of thin iron, iron wire, preferably varnished or oxidised on its surface, may be wound upon the

FIG. 4.



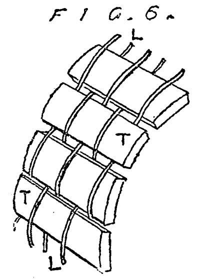
cylinder, as in the armature known as Gramme's, to serve as a magnetic core. Outside the core, whether constructed of washers or of wire, a layer of varnished paper or other insulating material is placed. The end washers may for greater strength be made thicker, and be secured to the spiders by screws. The core and frame so constructed secure great strength, requisite magnetic properties, proper insulation, and simplicity of construction. The armature coils are then wound over the core, which may,

FIG. 5.

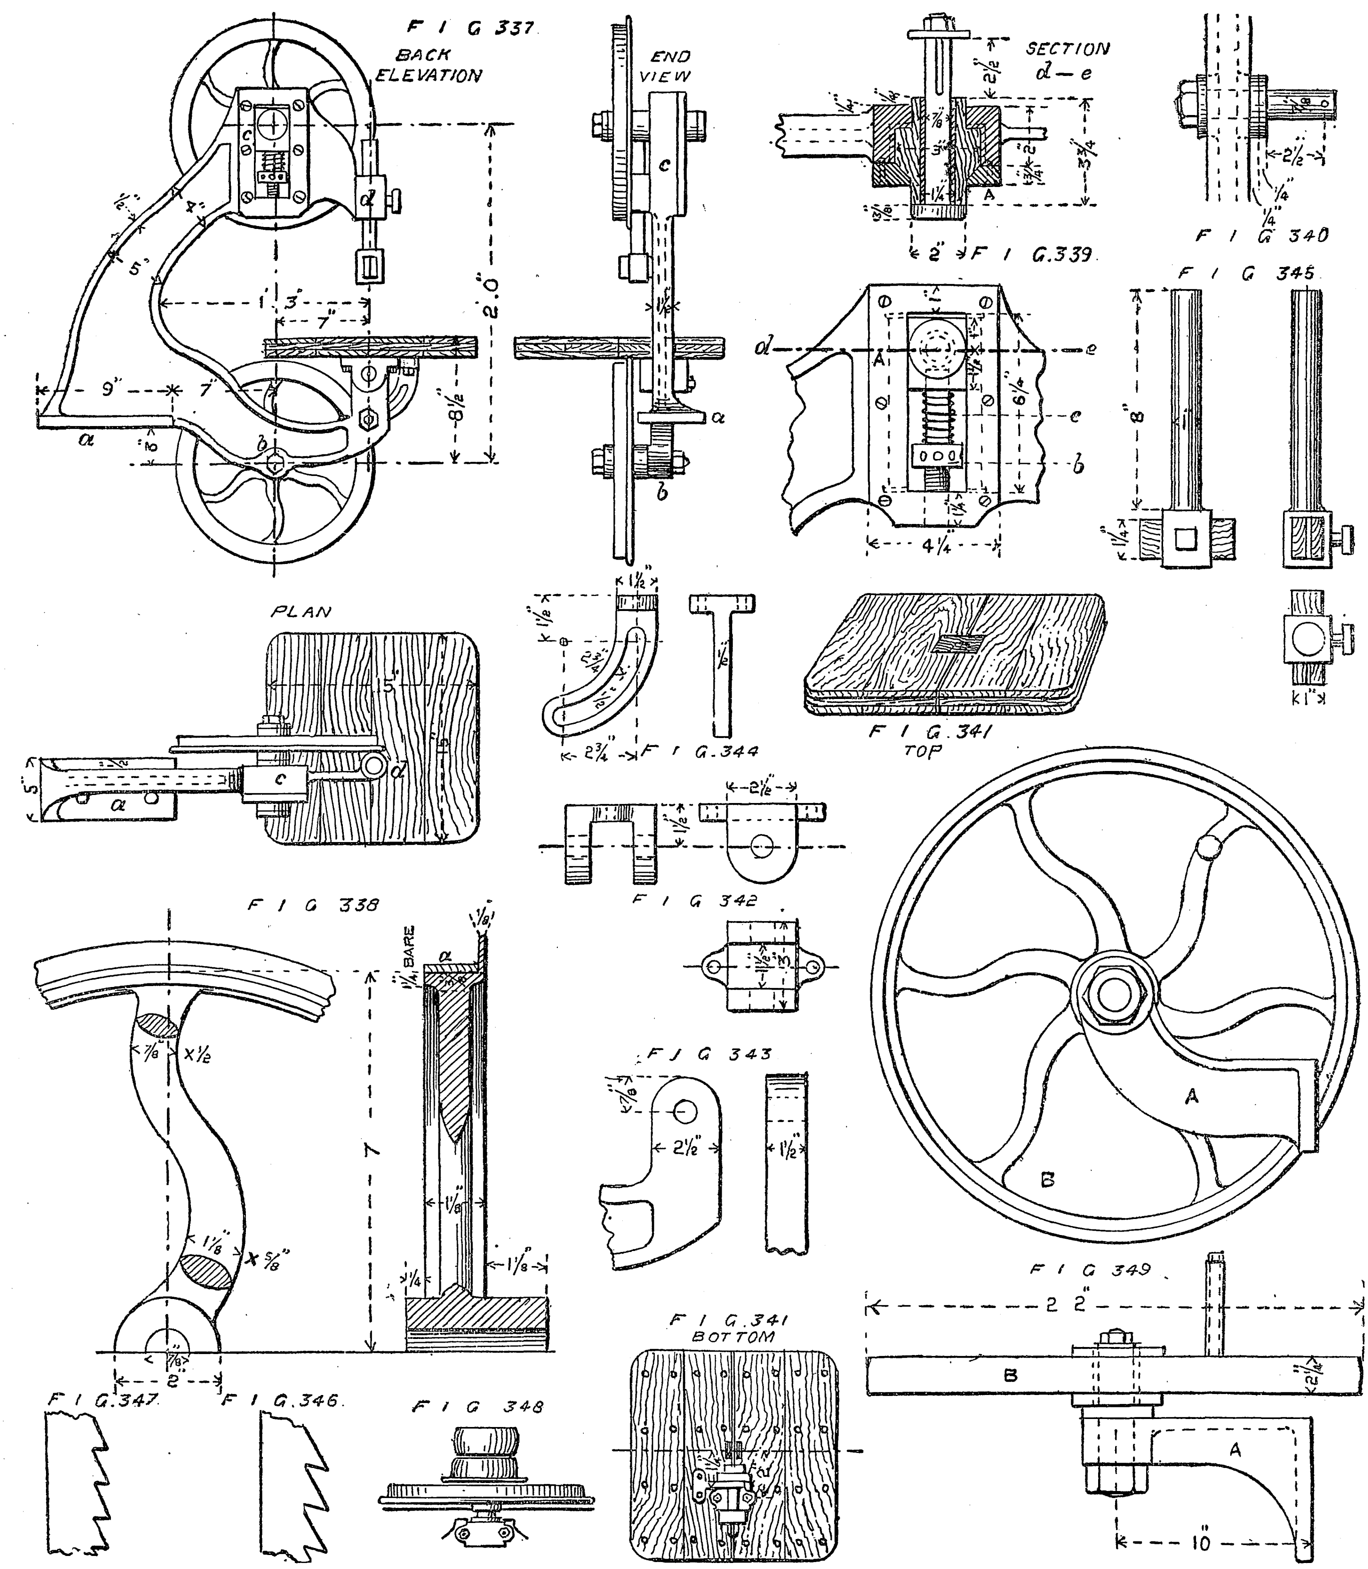


if so desired, be effected in any ordinary way, either ring-fashion or drum-fashion, but the patentee prefers the ring method of winding When armatures of low resistance are required (such as for electro-plating) he prefers to make the coils of thin copper tape, two, three, four, or more pieces of which are laid upon one another to form a single laminated conductor, which, after securing the usual insulation, is

FIG. 6.



wound over the core. This is more flexible than solid copper conductors. In some cases the patentee binds or weaves together the portions of the wires or tapes which lie on the external periphery of the armature by means of a peripheral lacing of thongs, or straps of leather, catgut, or dermatine, or other similar or suitable material, such as thin metal wires covered with suitable flexible insulation, the thongs or straps passing over one conductor



and under the next one, and so on after the manner of wickerwork, thereby holding the wires or tapes firmly in place, and preventing flying.

Where only one external layer of conductors is used, this layer may be woven before the ends of the conducting tapes or wires are drawn through the interior of the ring. Or if more layers than one are wound upon the core frame, the outer layer only of conductors may be thus woven or laced. Figs. 3, 4, 5, and 6 illustrate a method of carrying out the improved construction of armatures, S S being the spiders, A A the supporting mantles or cylinders, W W the iron washers, B B the outer layer of insulating material, D D the conductors.

In Figs. 3 and 4, these are shown as of ordinary insulated wire. In Figs. 5 and 6, they are shown as constructed of copper tape, T T. The method of securing the outer conductors by lacing or weaving with thongs or straps, L L, is shown at Fig. 6.

THE AMATEUR WORKSHOP.—XXX.

Band Saws.

THE advantage of a band saw over a jigger is that the cutting action is continuous, and, therefore, economical, and that the line of cut is only slightly obscured by the accumulation of sawdust. The attachment of the band saw to the table of a circular saw is convenient for two reasons—first, because very much labour is saved thereby—the labour of making a separate standard and self-contained mechanism for driving; secondly, because three wheels are readily applied to carry the saw, which wheels can be smaller in diameter than if two wheels only were employed. Thus the minimum diameter for a two-wheeled saw is usually fixed at from 20in. to 24in.; but where three are used, we may go as low as 14in. or 15in. On the other hand, the band saw framing crowds the table of the circular, and is in the way of cutting wide stuff. But this, though objectionable in a large shop, is not so, or at least, not to the same extent, where amateur work alone is concerned. If, moreover, we put the band-saw frame upon the side of the circular-saw frame instead of on the top, in order to gain a little room, we make too much depend upon the bolts themselves, the overhang of the frame putting excessive leverage upon them. But bolting it on the top, it is impossible for it to become shifted.

There are a number of important particulars to be regarded in the designing of band saws, and these we will note as they arise in succession. But first we will commence at the main framing (Fig. 337). The chief essential in this is rigidity, and the frame here dimensioned is stiff enough for the size of saw. In larger saws the box type of framing is usually adopted, but this would be too heavy in this instance. Note that the frame is carried backwards at a little below the level of the table in order to give room for cutting wide stuff. The pattern is made by halving together two horizontal pieces, one for the top arm, and the

other for the bottom, into a back upright piece, each being wide enough to allow of cutting the outline of the frame. These are glued and pegged, and when dry are struck and cut to outline. Fillets are fitted in—short pieces round the curved portions, in the manner described in previous articles, and a flange, *a*, for bolting to the table. A boss, *b*, is fitted at the lower end of the frame to receive the stud upon which the bottom saw pulley runs. The top, *c*, is thickened up and cored out to take the sliding block which carries the spindle of the top pulley. The end of the upper arm is formed into a boss, *d*, for carrying the sliding saw guide. The portion of the frame immediately underneath the table is thickened up to receive the hinge pin for canting movement.

When attempting to make a saw of this kind it would be better to buy the pulleys ready made of the saw manufacturers. They would then be already turned and balanced, and covered with indiarubber, without the trouble of making a pattern. If they are to be constructed, the patterns must be properly proportioned, preferably have curved arms, and be cast in moderately soft metal. The proportions given in Fig. 338 will insure a safe pulley. When cast, it is to be turned on the outside of the rim, around the flange, and inwards as far as the arms will permit, and the allowance for turning should be as little in amount as will permit of the tool getting under the skin, because the removal of much metal from any portion of a light casting of this description alters the conditions of tension, so that a pulley which would not break when first cast will often break when an excessive amount has been turned off the rim; and conversely, a pulley which would be correctly proportioned supposing it were turned, will break across the arms as a rough casting through too excessive an allowance of metal in the rim. The space between the arms which cannot be turned should be filed to merge into the turned portions. The boss will be bored and turned in the same chuckings as the rim. It is important that the pulleys should be truly balanced, on account of the high speed at which they run. Insert a spindle temporarily into the bored hole, and pivot on a pair of machine or other centres, and note if one portion of the circumference is heavier than the rest. If so, the excess of weight must be removed from the heavier side by filing.

Some manufacturers prefer to make the pulleys without flanges, on the ground that they have a tendency to break the saws. But it is, nevertheless, the usual practice to retain the flanges, and appears to me to be the safer course —at least, in the case of saws whose spindles are not provided with a set screw for correct adjustment. In ordinary machines, when the spindle bearings wear, there is trouble experienced by the saws running to front or back of the pulleys. To prevent them from running off at the front, taper is given to the rim, for the same reason as convexity is given to a belt pulley, and the flange prevents them from running off at the back. Of course, if the pulleys wabble, and the packing pieces and guides are not properly adjusted, the saws must break under the unequal strains to which they are subject.

The covering on the pulleys (Fig. 338, *a*) is sometimes made of guttapercha, but usually of indiarubber, or of leather. Its purpose is to form an elastic cushion for the saw, and so diminish the risk of fracture which would result if the saw ran on a hard, unyielding surface. The coverings are bought as rings, ordered to any length, and stretched over. An indiarubber ring will last for an almost indefinite time, certainly for six or eight years in constant use. It requires to be scraped from time to time in order to remove the resinous accumulation which clings to it. The objection to guttapercha is that it becomes partially melted with accidental overheating of the saw. Neither guttapercha nor leather is nearly so elastic as rubber, and therefore the last-named is to be much preferred.

What is termed the tension arrangement refers to the mode of adjustment of the top pulley. The bottom pulley centre is always fixed, but in order that saws differing in length within moderate limits, as, for instance, saws which have been broken and re-brazed not exactly to their original dimensions shall be used, the bearing of the top pulley is made to slide in vertical guides in the frame of the machine, and the amount of range will vary from 1in. to 4in. with the size of machine. The tension proper is an arrangement by which an elastic spring of some kind or other is interposed between the sliding bearing and the frame, so that the bearing rests on, or is supported by, the spring, in order that when the length of the saw alters by reason of expansion or contraction due to the heat generated in cutting, its fracture will be prevented by the elasticity of the spring allowing the bearing to accommodate itself to the altered length of the saw in a manner both sensitive and automatic, and which could not be effected by the mere operation of a screw and hand wheel. How many different kinds of tension arrangements there are I cannot tell, since each maker seems to have his own mode of construction, and several are the subject of patents. In a limited number of machines the tension is given by means of a lever, which is so weighted as to counterbalance the weight of the wheel, and to impart besides the elastic tension necessary to maintain the saw taut. The end of the lever is in some cases cut into the form of a segmental rack, engaging with straight rack teeth on the sliding block which carries the top wheel. In some, again, the lever is attached to a stirrup fastened to the top of the slide; in others, it lifts against the underface of the slide, being pivoted to the main framing. Lever tension was formerly universally employed, but is now generally superseded by the spring. The principle of the latter is, that while the slide is moved vertically up and down by means of a screw and hand wheel actuating a nut fastened to the slide, a certain amount of vertical movement is possible to the whole combination—hand wheel, screw, nut, and slide at once—quite sufficient to compensate for the various alterations due to temperature in the length of the saw. In some machines the spring is a thin plate arched like a carriage spring, but differing therefrom in comprising a single lamina only, and the pressure of the spring is capable of adjustment and regulation within moderate limits, and bears either against the boss of the hand wheel or the end of the screw. But in the vast majority of cases the ordinary coiled spring is employed, and this is what I have adopted, though not in the combination in which it is usually found. In fact, this machine is not an orthodox design in all matters of detail, but about as simple an affair as can be, without sacrificing efficiency. The top part of the frame is, as we just now noted, cored out to receive the sliding block which forms the bearing of the saw spindle, and into this recess the block is fitted closely, yet freely; by shaping when practicable, and if not, by filing. Note that near the ends of the sliding ways (Fig. 339) the metal is cored out for a width of about ⅜in. to a depth a trifle below the sliding surfaces. This is done to save the unnecessary trouble involved in shaping right into the sharp angle. Both faces of the block are not alike, but while the front one is square, the hinder one is vee'd like a machine slide. Then the plate A, which is screwed on the face of the slide, allows of the introduction of the block, and affords a means of adjustment for wear against the faces, and so prevents the tipping of the spindle out of the horizontal which would result from a slack fit. The block is prolonged beyond the plate to give sufficient length of bearing, and is also brass bushed and provided with an oil hole or a proper lubricator. The block itself has a vertical range in its slides of about 1in. upon the end of the screwed pin *a*; the circular nut, *b*, provides the means of adjustment; the spring, *c*, which becomes the elastic cushion for the wheel and block, intervening. When it is desired to alter the centres of the wheels, the weight of the upper one is lifted by one hand, and the circular nut run up or down by the fingers of the other until the proper height for the pulley is obtained, then two or three turns of the nut by means of a podger against the spring imparts the requisite tension to the latter. A hand wheel, screw, and nut would mean more work than this, and though slightly more convenient, is hardly worth the trouble for an amateur's machine. Fig. 340 shows the bottom pin *b*, in Fig. 337. The table may be of cast iron of about ½in. in thickness, stiffened with a rib about ½in. × ¾in. deep carried around its lower edge. But I have shown one of wood (Fig. 341) made by crossing three thicknesses of ⅜in or $\frac{7}{16}$in. thoroughly dry mahogany, the whole being glued together and screwed from the under face. The canting motion is provided for by a simple hinge, the casting (Fig. 342) being screwed to the bottom of the table (Fig. 341), and embracing the lug on the main framing (see Fig. 343.) A turned pin connects the two. The table is clamped in any position through the medium of the quadrant plate (Fig. 344) and pinching screw, and when the end of the slot in the plate is checked by the stud, the table is in a horizontal position. The saw groove in the table is bevelled downwards and backwards to right and left of the actual saw faces to prevent pinching of the table against the saw while canting.

We now come to an important section of the work—the adjustable guides for the saw blade. When material is being cut there is pressure of the material tending to force the saw backwards; and when cutting curves there is also the twisting action bending the blade out of its proper plane; and the heavier the work, and the quicker the curves, the more injurious is this action. To prevent the first, many makers place a small hardened cast-steel wheel or roller immediately behind the saw, and running in bearings on the adjustable guide shown at Fig. 345, so that there is rolling friction set up between the saw and roller. Instead of the roller a plate of steel is sometimes substituted, and rubbing friction is allowed to take place. A hard wood roller is also used, and has this advantage—that it can be readily replaced when worn. I have shown neither of these plans, preferring the simple arrangement of Fig. 345. The guide (Fig. 345), adjustable vertically, carries a socket, and into this fits a block of hard wood, having a kerf cut in it just wide enough to receive the saw blade, and brought up and set by the screw to bear against the back of the saw. This can be readjusted or replaced as it wears, and is perfectly efficient. Two slips (Fig. 341) are fitted into the table top for a similar purpose, and these also can be replaced at intervals as they become worn.

Very little lubrication suffices for a band saw if it is not forced overmuch. The usual mode of lubrication is to place a wad of tow saturated with tallow behind the saw, and resting on the upper wooden guides. If the saw is kept in trim, and not overstrained or forced, this should prevent immoderate heating, which is the source of frequent breakages.

The repairing of broken band saws is done by filing a scarf joint of 1in. or 1½in. in length, binding it together first with iron binding wire and then with brass wire. The saw is moistened with spirits of salts or with water, powdered borax is sprinkled over it, and the joint put into the clear heat of a smith's, or better still, of a charcoal fire, until the brass runs into the joint. The saw is then immediately removed to cool. Some use a pair of red-hot tongs in preference to the fire. When cold, file the joint to the same thickness as the rest of the blade (this is an important point), and file the teeth ready for use. A well-brazed joint is as strong as any other part of the saw, and is, I think, even less apt to break. Burning of the blade should be guarded against as a source of after-fracture.

The teeth of band saws are variously modified according to the work which they have to do. When discussing circular saws we remarked in effect that teeth whose shapes are theoretically incorrect will nevertheless do good work. In hand saws and pit saws this is not the case, but each description of timber, dry, wet, fluffy, hard, or harsh, requires some corresponding modifications in set, angle, rake, &c., because there being no excess of power, any want of adaptability in the saw for its work at once asserts itself. Band saws occupy an intermediate position, because, though driven by power, they are fragile, and liable to break when forced to their work. Hence the conditions which we laid down when speaking of circular saws should be regarded in the case of band saws. For soft woods the teeth will be coarsely spaced and set, and have forward rake. For hard woods the spacing and set should be finer, and the teeth have no rake at all, or very little. Fig. 346 shows a typical tooth for soft, Fig. 347 one for hard wood.

In conclusion, there is the question of driving power. Since this saw is designed specially to go on the bench of the circular figured in our last, it is driven from the pulleys on the

circular saw-spindle, the latter being lengthened beyond the dimensions there given (Fig. 323, p. 232) to receive the third band-saw pulley (Fig. 348.) The question of motive power does not affect the relative arrangements of the band and circular saw pulleys which are shown in Fig. 348, the band-saw pulley being keyed on the spindle. When the circular saw is running, and the band saw not required for a considerable time, the latter should not only not be allowed to run, but the tension should be removed. This is done by lowering the top saw pulley, and either removing the saw altogether, or by letting one lap rest on the table, and the other on a pin or peg at the side of the circular saw pulleys. Or as an alternative, the band-saw pulley on the circular-saw spindle could be made a free fit thereon, that is without a key, and temporarily held to the driving pulley of the circular-saw spindle when required by means of a turned pin passing through a boss on one of the arms of the former into a hole in the body of the latter, but the former arrangement is equally efficient.

If the saws are to be driven by power our task ends here, but if by hand, a wheel and bracket must be designed. The bracket may take the form of Fig. 349, A, and be bolted at that end of the table opposite to the band saw. A suitable wheel is shown in Fig. 349, B, but the design is quite arbitrary, and any wheel approaching to this in dimensions can be utilised.

HYGIENIC MEDICINE.

OUR readers are familiar with the opinions of Dr. Allinson as they have appeared in our columns. The second edition of his "Hygienic Medicine" lies before us; in it are many questions of vital importance. The doctor discusses man's place in nature, and says we ought to be placed among the Frugivora or fruit eaters. He is of opinion that our civilisation is the cause of many of our diseases. He blames the close confinement of our houses with the production of respiratory diseases; and also that the artificial warmth due to fires, clothes, and hot foods and fluids is injurious. Many civilised men, he thinks, do not get sufficient exercise, whilst others bring on disease by not keeping their skins clean. On the question of food, Dr. Allinson is very particular. He argues, from man's structure, that men should live on fruit, grain, green vegetables, nuts, and other vegetable products. He says that three meals a day, about five hours apart, are enough, and that the food and fluids should be taken only lukewarm, and not scalding hot. He points out, and justly, that we do not eat enough fruit, but take it as a luxury instead of an essential article of diet. We eat it at the end of a meal instead of making a meal of it with bread. He denounces alcohol and tobacco as unphysiological. To bad air he blames all our respiratory diseases and chest complaints, from influenza to consumption, and that infectious diseases are worst where there is least pure air, as amongst the poor. According to Dr. Allinson, "all diseases are one with different names, according to the locality where they manifest themselves." He has only one disease, and that is a wrong or unhygienic state of the system. He says, "It matters not of what disease you die; if you die above a certain number per thousand" we are doing wrong. Having only one disease, he has only one remedy, and that may be summed up in the term "Hygienic living"—i.e., in proper food, at proper intervals, pure air always, regular exercise, and clean skins. When he writes of drugs, he declares that they are useless as curative agents—in fact, instead of helping cure, he believes they retard it. He allows the use of drugs for two or three purposes; to kill or expel parasites that are on the skin, as the itch, or in the intestines, as various worms. Also to produce anesthesia during surgical operations, and occasionally to allay pain in incurable cases, such as cancer. Otherwise he objects to their use in ordinary diseases, and banding all the drugs together, he brands them as poisons and life-destroyers. How he would treat a case of ague without quinine we do not know. He objects to the free use of the knife, and says that many surgical diseases would be best treated by hygienic treatment alone, and not by surgical interference. This is the outline of the book, and though we cannot agree with all he writes, yet he makes out a good case for himself. We should advise all our readers to buy a copy of this book, and study it for themselves. The price is 1s.; it can be got from the author at 29, Charlotte-street, Portland-place, W., post-free for thirteen stamps; or from Pitman, Paternoster-row, E.C., the publisher. It will repay perusal.

HALF A CENTURY OF RAILWAY WORK.

ALTHOUGH the past half-century has witnessed a great change in railway work it is not a little remarkable that in all the chief characteristics there have been no essential changes in the practices which were adopted after a few years of practical experience. Improvements there have been, it is true; but they followed the onward march of progress and invention; and if modern engineers had to do what was done by the pioneers of railways, and with only the resources available at the time, they would act much in the same way. Those who were old enough to take an intelligent interest in the work of the early railway engineers more than half a century ago are becoming fewer every year, and it is only occasionally that they refer to the work of former years. Mr. Edward Woods, the President of the Institution of Civil Engineers, took occasion, in his inaugural address at the opening of the session, to refer to some matters which are within his personal cognisance, and are not without interest to railway men of the modern school. Thus, his connection with the profession dates from the time when he entered the service of the Liverpool and Manchester Railway Company — a line which was the example and pattern of its immediate successors. That line was originally laid with the so-named fish-bellied rails of 35lb. to the yard, resting in iron chairs supported on stone blocks wherever solid ground permitted their use—wooden sleepers being used only as temporary supporters. Stephenson himself took advantage of the rocky bed of the Olive Mount cutting, near Liverpool, to form a bed on which the chairs should directly rest. Owing mainly to the enormous traffic which rapidly developed—it is said that loads of 250 tons were hauled by locomotives like the Samson—the rails were frequently broken, and it was quickly seen that the "road" was too rigid, and it was, therefore, relaid, piecemeal, with rails of 50lb., 62lb., 72lb., and latterly with still heavier metals, while stone blocks were discarded for the more elastic wooden sleepers and the compressed wooden key in preference to the iron wedge which was formerly deemed necessary for holding the rail in the chair. Nowadays steel sleepers are coming into vogue in place of wood, especially in India, but they are so formed that they give a maximum of elasticity and avoid that fatal blunder of the early railway engineers—a rigid road-bed. Steel rails have supplanted iron, and can now be bought for £3 10s. per ton, whereas in 1870 iron rails, which have a life of only about one-third of steel, cost £7 10s., the price of the better quality being then about £10 per ton. Mr. Woods, referring to the locomotives, remarked that the present advanced type retained the essential characteristics of those which held the field at the commencement of the half-century. There is the water-surrounded furnace chamber, the multitubular boiler, the wheels on crank or straight axles, single or coupled, driven by a pair of horizontal or inclined cylinders, the smoke-box, and the steam blast. Great improvements have no doubt been effected in most of the constructive details —probably as great as in the external appearance of the engines,—but the essential features of the locomotives of fifty years ago are still to be seen. The modern engines possess at least four times more steaming power, coupled with six-fold weight, which means adhesion—an important factor in calculating their hauling power. From 1832 to 1836 the "Planet" was the approved type; but, compared with a modern locomotive, the weight appears as 7½ tons to 45 tons, the fire-grate area as 7 sq. ft. to 20 sq. ft., and the heating surface as 300 sq. ft. to 1,400 sq. ft. As to the consumption of fuel, the economy that has been effected almost passes the bounds of credibility. Thus, about fifty years ago the consumption of coke on the Liverpool and Manchester line amounted to 12,600 tons per annum; but a few years later 3,100 tons sufficed for a traffic of greater volume. The expansive working of the steam and the use of higher pressures—now up to 180lb.—had much to do with effecting the economy, and since 1852 coke has been supplanted by coal, an increased area of firegrate, permitting of slower rate of combustion, and a larger capacity of furnace, with appliances therein for maintaining high temperature of evolved gases, having solved a problem which must have puzzled the early railway engineers. The tractive power has increased five-fold, and inclines which at one time were considered too severe to be worked by locomotives are now readily surmounted. The recognised limit of gradient is about 1 in 20, for beyond that the weight necessary to be given to the engine to secure adhesion absorbs, by reason of the gravity of its own mass, the greater part of the power it is capable of exerting. Increased speed, so far as the bulk of the traffic is concerned, is another feature, though as regards express and special trains there is little advance to chronicle; but in all the accessory details of railway work, such as signalling, switching, braking, &c., there is a great and important advance. Referring to the growth of railways in the Colonies, Mr. Woods spoke of the question of gauge, and mentioned a fact which the Australians will regret some day. Instead of profiting by the experience of the mother country, we find that in New South Wales the gauge is the standard 4ft. 8½in.; in Victoria, 5ft. 3in. (in some places 3ft. 6in.); and in Queensland, 3ft. 6in.; South Australia has two gauges, 5ft. 3in. and 3ft. 6in.; while Western Australia, like Queensland, has a gauge of 3ft. 6in. This mixture cannot but have a retarding effect on the development of the railway system in Australia, and whatever may be said in favour of this or that gauge, the President of the Institution of Civil Engineers might have spoken with more severity than he did of the folly of a young and growing country mixing its railway gauges. The experience of the Old Country and of America should have warned the Australians that in course of time they will either have to put up with increased cost of working or make the gauge uniform. The next fifty years is scarcely likely to witness so much improvement as has taken place in the last half-century; but there is still much to be done before railway working can be considered as perfect as it is possible to make it.

RECENT IMPROVEMENTS IN MICROSCOPE OBJECTIVES.*

SCARCELY ten years have passed since Professor E. Abbe, of Jena, presented to the scientific world his theory of vision with the microscope, which resulted from a long series of investigations conducted mainly by Helmholtz and himself. It is not my intention to enter upon a general discussion of this theory, but rather to present, as briefly as possible, an account of the practical results to which it has led.

Did time permit, I would be pleased to review the progress that has been made during the last twenty or thirty years, but I must refrain. The microscope is capable of separately defining lines or markings as close together as the 1-115,000 of an inch. This is about the limit of resolution with white light, the theoretical limit being somewhat higher. The length of a vibration of red light is about 1-39,000 of an inch. How is it possible to resolve a band composed of lines ruled so much closer than a wave-length of light? Obviously, such minute spaces cannot be imaged by the dioptric method illustrated in the textbooks in explanation of the action of the microscope. The effect of such a band is to break up the rays by diffraction, and Professor Abbe has shown that, in order to resolve a band of lines as close or closer than 1-39,000 of an inch, it is necessary that the several diffraction spectra produced by the illuminating pencils be taken up by the object-glass. These spectra are imaged back of the objective, in its upper focal plane, and may be seen by removing the ocular and looking down the tube of the microscope.

By the combination of the spectral images, which are images of the source of light, or of the diaphragm, opening, in the conjugate focal plane

* By ROMYN HITCHCOCK, F.R.M.S., in the *American Monthly Microscopical Journal.*

of the object, the image of the refracting elements is produced, by interference.

The closer the lines the greater will be the number of diffraction spectra. When we observe a lighted candle through a diffraction plate the closer the lines the more images will be seen. It will be obvious, therefore, that since the portrayal of the structure depends upon the gathering in of the diffraction spectra by the object-glass, it is important that all the diffraction spectra should be so taken up, for each series of spectra will produce a definite number of lines in the image, and no more, independently of the structure of the object. The number of spectra that an objective will collect, the successive spectra being formed further and further from the optic axis, will depend entirely upon the angular aperture of the lens. We are thus able to understand the value of angular aperture, and we see at once why it is that resolving power increases with angular aperture.

The spectral images portray only the minute structure of an object. In addition to this we have the images of grosser parts formed by the ordinary dioptric action of the lenses. The skill of the maker is severely tested to bring the dioptric and diffraction images into the same plane. In the resolution of a diatom frustule, such as you will see this evening, we have the dioptric image of the outline and the central longitudinal line and the diffraction images of the cross markings. In the case of Nobert's bands of lines ruled on glass there is no dioptric image.

It results from the facts stated above that the images of minute structures seen in the microscope are interference images, and are, to a certain extent, independent of the details of the structures under examination. In other words, whatever elements will give identical diffraction spectra will be portrayed as identical structures. Moreover, in the case of bands of lines, by excluding certain spectral images and admitting others, the number of lines in the image, supposing the object to be a band of ruled lines, may be doubled. Various other modifications may be made in the image, which time does not permit me to mention.

Having thus reviewed the present theory of microscopic vision in a very superficial manner, it remains to consider the improvement in the construction of microscope objectives which the theory has led to. The greatest improvement of late years has been the adoption of a system known as homogeneous immersion, in which the front lens of the objective is brought into optical contact with the object or the cover-glass by means of an immersion fluid having an index of refraction the same as glass. It is assumed that rays from the object pass without refraction from the object to the objective. With such lenses the angular cone of rays entering the front lens is much smaller than that entering a lens without an immersion medium; nevertheless, a greater number of diffraction spectra will be taken in by such a lens.

Owing to the effect of the immersion media, it is evident that while increase of angular aperture in any medium gives greater power of resolution, the same result may be attained by reducing the angular aperture and the use of an immersion medium of higher refractive power.

Therefore, the term angular aperture is not sufficiently definite for practical purposes, and Prof. Abbe has introduced the term numerical aperture, which is the product of the index of refraction of the medium multiplied by the sine of half the angular aperture in that medium, *n* sin. *u*. It expresses the resolving power of an objective, of whatever kind it may be, dry or immersion. A table of numerical apertures, with the theoretical power of resolution corresponding to them, is published in the microscopical journals. From such a table I have selected some figures to illustrate the subject.

N.A.	Air Angle	Water Angle	Oil Angle	Resolving Power (Line *e*.)
	° ′	° ′	° ′	
1·52	—	—	180	146,521
1·33	—	180	122 6	128,212
1·00	180	97 31	82 17	96,400
·94	140 6	89 56	76 24	90,616

It will be seen that a numerical aperture of 0·94 gives a resolving power equivalent to a dry objective of 140° 6′, angular aperture, a water immersion of 89° 56′, and a homogeneous immersion of 76° 24′. The highest possible numerical aperture in air is 1, in water, 1·33, but in a homogeneous medium 1·52.

The resolving power of an objective is calculated by the formula $\delta = \frac{\lambda}{2a}$ in which λ = the wave-length of the light, and a = aperture. According to this formula, the number of lines that can be resolved by an objective of the highest possible numerical aperture is with white light ($\lambda = 0{\cdot}5269$) 146,543 in an inch, with blue light ($\lambda = 0{\cdot}486$) 158,845, and with the actinic rays which may be used in photography ($\delta\ \lambda\ 0{\cdot}4000\ \mu$) 193,037. Practically the limit is considerably lower. The homogeneous immersion lenses made by Mr. Zeiss do not generally have a numerical aperture above 1·30.

The greatest resolution yet made, so far as I am aware, with any lens is the 19th band of Nobert's plate, having about 112,000 lines to an inch. It is probable, indeed, almost certain, that this limit can be exceeded with the fine objectives now made, but authentic records that it has been done are as yet wanting. Ambitious amateurs have reported resolutions of 120,000 and more, but the results cannot be accepted without question, particularly when they are in excess of the theoretical limit. As an indication of how easily observers are sometimes deceived in such work, I have a photograph of *A. pellucida* showing spurious lines which were supposed to be an indication of longitudinal markings.

It may be incidentally remarked that the resolving power is a function of angular aperture, independent of magnification. Sufficient magnification is required to cause the markings resolved to subtend an angle such as will enable the eye to distinguish them. Beyond this point no possible increase of magnification can disclose additional structural details.

The question of resolution of close lines or particles is entirely distinct from that of the visibility of isolated lines or particles. A line one millionth of an inch in diameter may be seen, but a space of 1-175,000 of an inch between such lines will probably never be seen.

A subject closely connected with the discussion of the aperture of microscope objectives is the consideration of mounting media. The optical character of the substance in which an object is examined is of great smportance as regards the visibility of the object. The visibility of an object is proportional to the difference between the index of refraction of the object and that of the medium in which it is mounted. Canada balsam has been universally used, and is certainly a very useful and convenient medium, but more highly refracting media are now demanded, and quite recently Prof. H. L. Smith, of Hobart College, has published several formulas for preparing compounds with refractive indices of 1·7 to 2·4. The best of these is probably a solution of antimony bromide in boro-glyceride dissolved in glycerine. This medium was first described in January of this year, and is but little known. The very highly refractive medium mentioned above is realgar, arsenic sulphide, which may be used alone or dissolved in arsenic bromide.

Dr. Morris, of New South Wales, has used sulphur for mounting and also selenium, the latter having an index of refraction of 2·6. Prof. W. H. Seaman has prepared an excellent medium by dissolving sulphur in anilin.

So great are the advantages of these media that a few persons have been led to believe they in some way increase the resolving power of an objective, and enable one to do as much with a lens of low angular aperture as can be done when balsam is used with another of greater angle. Obviously this is not true. The distinction between visibility and resolution should be clearly drawn.

RECOVERING SILVER FROM PHOTOGRAPHER'S WASTE.

THE following hints on recovering silver from photographer's waste are by Mr. A. C. Hopkins, in *Anthony's Bulletin*:—In common with most photographers, I have a small dark room, but because there is a sink and waste-pipe in the room I do my toning there. At the end of the sink I had, until recently, a large barrel into which I poured the first two or three washings from my prints, and to which I would occasionally add a handful of salt. When the barrel became full (which took a week or ten days), I put in more acid to clear it up, as directed in a circular issued by the refiners. But I found that it did not clear well, either because I used too much salt or not enough acid; and, drawing off the water before it had settled, I knew that I was wasting a great deal of silver. Then, too, a barrel of stagnant water, standing in a small room, is not conducive to health or comfort. So I decided to dispense with mine, and found a substitute in the following simple process:—

After soaking my prints for five minutes in water made slightly acid by acetic acid, I remove them to another dish, and add to the water from which I have just taken them about a teaspoonful of salt, and stir it rapidly for a moment with the hand, when it becomes as white and thick as milk. This solution I then pour into a common wooden pail, which will hold enough water for the first washing of a hundred prints, and the next day, when I am ready to tone again, I find that my solution has become perfectly clear, and in the bottom of the pail I have a clear white sediment—pure chloride of silver. I then pour off the water to within an inch of the bottom, and the pail is then ready to be filled again. I find that by adding salt to the second water in which I washed the prints, there is hardly a trace of silver, and it is not worth saving. About once a month I pour the settlings from the pail through a fine cloth to filter, and throw the cloth and contents into the silver paper clippings. In this way I save more than half of the silver used in making the print.

REMOVAL OF SUPERFLUOUS HAIRS BY ELECTROLYSIS.*

By JAMES STARTIN,

Late Surgeon and Lecturer at St. John's Hospital for Diseases of the Skin, Consulting Surgeon to the Sheffield Public Skin Hospital.

UNTIL the last two years, in England the removal of superfluous hairs from the face has been an unsatisfactory operation. Superfluous hairs that grow on the face, upper lip, and chin of women, and sometimes on the noses of men, are always a source of annoyance, and very naturally they desire to have them removed.

In the summer of 1884 my attention was turned to the removal of superfluous hair from the face by reason of several cases coming under my notice, the patients in most instances complaining of the very unsatisfactory results obtained from the use of depilatories. In the autumn of that year, in answer to an inquiry in the *Lancet*, I recommended the process of destruction by electrolysis, having then had several successful cases. In consultation with my friend, Dr. W. Kilner, electrician to St. Thomas's Hospital, I devised the apparatus required—that is, I had made for me by Mr. Groves, of Bolsover-street, a nice portable case containing a small twenty-cell bichromate battery, which can be regulated to three powers at will, two ordinary sponge electrodes, two yard-and-a-half wire conductors, and a needle-holder, devised much like an ordinary pen-holder. I found, after considerable trial, that toughened gold, well sharpened, was the best material, and wore the best.

Now, with regard to the operation. The application of the needle electrode cannot be made without more or less pain, varying much in different patients, no matter how the sponge electrode is applied. I then, after a prick or two of the needle electrode, brush over the part a 5 per cent. solution of hydrochlorate of cocaine, with good result, almost invariably deadening the pain. In one or two instances I have had an anæsthetic administered; but I find this is seldom necessary, as the pain is slight. The operation can now be proceeded with. The negative needle electrode is plunged into the root of the hair for about $\frac{1}{16}$in., and the positive electrode sponge is applied in the immediate neighbourhood. The needle should be kept in for about the space of five seconds, then the sponge electrode should be removed, and afterwards the needle electrode. To know that the operation is effectual, the needle should produce slight frothing of the tissues. The hair destroyed can now be easily epilated with an ordinary pair of dressing forceps, and it should come out without the slightest adhesion. This operation applies more especially to hairs that are noticeable to the naked eye. Fine downy hairs can always be destroyed by the application of a properly made depilatory. A slight inflammation of temporary character occurs for an hour or two after the operation in the destroyed follicle; this can be controlled by the use of a soothing lotion. The operation, if carefully done with a battery in good working order, is invariably successful, especially if the hairs are few and of good size—from $\frac{1}{4}$in. to $\frac{1}{2}$in. long. If many hairs have to be removed, then several sittings will be required at intervals of about ten days. A hundred hairs can be removed at a sitting. The following cases may serve to illustrate the operation.

1. A young woman, aged thirty-two, consulted me on March 15th, 1884, with superfluous hair on the upper lip and chin; she had pulled them out herself, and there remained about a hundred short, dark, stumpy hairs. I removed in two sittings as many as I could see; for the removal of the remainder I prescribed a depilatory for her to use. I recently saw this patient, showing the result of the operation to be successful.

2. In August, 1884, a young lady, aged thirty, was sent to me from the north of England, who had had a superfluous growth of hair on the upper lip and chin for about five years. I removed all I could see in two sittings. I heard recently that the operation was successful.

3. I removed a patch of superfluous hair from the neck of a young lady last August, and I received a letter from her mother last week to say the operation was successful.

4. In October a young woman came to me to have a large quantity of hairs removed from the chin and upper lip. This was the worst case I have had, both from the numbers of the hairs, their depth of growth, and the extreme sensitiveness of the patient to electricity. I used the electrode with

* From the *Lancet*.

difficulty after painting the skin with a 5 per cent. solution of hydrochlorate of cocaine, and could only remove about fifty at a sitting. After seven sittings I have nearly accomplished their removal.

5. A gentleman consulted me in the summer of 1885 for a few superfluous hairs on the tip of the nose. I removed these at one sitting, the result being successful.

6. In July, 1885, I removed about fifty hairs 1in. in length round the nipples of the breast of a young woman, also some from her upper lip. One operation proved successful.

Since I wrote this paper I had the honour to show my battery and electrodes in the museum, and demonstrate the process in the surgical section to the president and members, at the meeting of the British Medical Association in August last, in connection with the destruction of the lupus nodule, moles, warts, and nævi, in a paper on the "Surgical Treatment of Lupus and Acne" I read at Brighton.

Sackville-street, W.

CROSS-CUT SCREW CAMS.*

THERE are various methods of changing a rotary motion into a reciprocating motion, but not all are equally adapted to similar situations and to the same purposes. The crank, the eccentric, pinion and racks, heart-wheel cam, worms, gear wheels and chain and other devices will develop a reciprocating movement from a rotary motion, but they are not all suited to all requirements. Perhaps no one of them is entirely satisfactory in some circumstances. In the writer's active mechanical experience it became necessary, after tests of the crank and heart-wheel cam, to resort to a cross-cut screw to produce a thoroughly equal motion that would instantly reverse and instantly return.

This peculiar cam is less used than its merits deserve, partly from a belief that it wears out rapidly, and partly, mainly, because it is thought to be difficult of production. These objections are neither of them valid; the cross-screw cam will last forty years if properly cared for, and any machinist who can cut a thread in a lathe, and who wears a common-sense head, can make the cam.

It is a cylinder threaded with a square thread screw, right-handed, and one of the same pitch left-handed; the thread of one direction crosses that of the other direction, so that when it is finished the screw presents a series of "lands" of a diamond-shaped area separated by crossed threads.

Of course it is quite easy to cut a single thread; but to cut another thread crossing the first requires some care. This necessity for care is increased from the fact that neither of these threads "run out"—are cut to the end of the blank—but at each end they join together, so that when finished a shot or other round pellet can be made to traverse the grooves, back and forth, simply by turning the screw as though on its axis. In fact, a follower does thus traverse these grooves. The follower is a crescent-shaped blade, conforming to the diameter of the screw or cam at the bottom of the thread, and pointed at each end. It is pivoted to a slide so as to turn freely. Now it follows that if the screw cam is turned on its axis, the engaging blade, or crescent-shaped follower, will move along in the grooves, carrying with it the slide to which it may be attached, and when it has reached the thread in one direction it will swivel or turn in the other direction, retracting its course. The follower may be swivelled to a fixed object, and the rotating screw cam be forced to slide on long journals, and thus become the reciprocating movement. There are instances when this adaptation would be desirable and preferable to the other; in many cases there would be less friction attending the sliding of the rotating screw cam than in the sliding of a bar.

The length of the screw cam or the distance of its stroke is not material; it may be adapted to the conveniences of the machine, and the length of stroke of the slide or other piece to be reciprocated may be determined by a lever pivoted to the slide to which the crescent-shaped follower is swivelled.

To make a cross-cut screw cam the diameter and length of the blank should first be determined, under such limitations as the character of the machine will permit; but an outer diameter of less than 2in. is not advisable, and the pitch of thread should be governed largely by the diameter of the blank. For a blank of 2in. diameter a pitch of $\frac{1}{4}$in. is not too fine; the coarser the pitch the larger must be the turn or curve where the right and left threads connect at their ends. The groove of the thread should be less than the lands; thus, in a pitch of four to the inch let the total of the width of the grooves at the surface be $\frac{13}{32}$in., and that of the lands $\frac{19}{32}$in. The grooves should be slightly inclined, making the sides of the threads tending slightly to the V form.

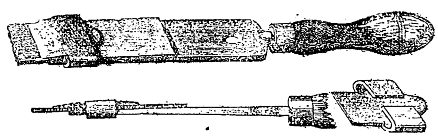
To cut the threads, the blank, after having been turned true and finished, should be dogged in the lathe, and the dog wedged to the face-plate to prevent all back lash. Calculate the number of revolutions of the screw cam required to make the traverse desired. In the case of the 2in. blank and the four-threaded pitch, 4in. traverse will be got by sixteen revolutions, and $3\frac{1}{2}$in. traverse will require fourteen revolutions. Draw a line longitudinally across the face of the blank, as it is on the centres in the lathe, by sliding the tool carriage along, with a pointed tool in the tool post. Turn the blank half way around and make another longitudinal mark. Then with the same tool make a mark around the blank at the starting point near the end, and another at the other end, the two being exactly so many inches and fourths of inches apart, as each entire revolution makes one-fourth of an inch in this case. Now drill two or three holes just inside the circumferential line, close together, and of the same diameter as the width of the score of the contemplated screw. The first of these holes should have its outer edge just on the circumferential line, the next a mere trifle inclined to the direction of the proposed thread, and if a third is made the same instruction is applicable. Similar holes are to be drilled at the other end (half way round) of the blank, with an opposite slight inclination for the return, or left-handed thread. These holes are the starting and the ending points of the screw-cutting tool. They are drilled the same depth as the scores of the screw are to be, as they are but continuations or connecting portions of the score. As the cutting-tool approaches the end at each chip it may be necessary to bring up the cut by hand-pulling the lathe belt. When the right-hand thread is completed cut the left-hand in the same way; the joinings will be where the holes were drilled, and will be slight curves on a radius corresponding with the pitch of the threads.

For these screw cams cast iron is greatly to be preferred to wrought iron. Larger blanks and coarser pitches than named above may be used, but a pitch of more than two to the inch is too rank to permit an easy turn at the ends.

* By JESSE H. LORD, in the *Manufacturers' Gazette.*

WRIGHT'S SCRAPING TOOL.

IN the annexed illustrations is shown an invention, patented by Mr. J. Wright, of Torrington, Connecticut, which gives a peculiar elasticity to the scraper, and allows of the smooth working of the tool. Secured to a suitable handle



is a bar of uniform width throughout its length, but diminishing in thickness from the end next the handle. Fitted to the bar is a clamp, shaped as shown in the enlarged view. The thin end of the bar is inserted between the arms and body of the clamp, and a hardened and tempered scraping bit is placed between the clamp and the bar. When the clamp is driven on the bar, the latter causes the clamp to draw tightly against the bit, which is held firmly in position for use. By means of this improvement, the bit may be made of uniform temper throughout its entire length, and may be moved forward as fast as it is worn away by grinding.

The "Air Telegraph."—The Edison-Gilliland-Smith system of telegraphing to and from trains without a direct connecting wire—the system described by Mr. Edison as the "air telegraph"—is now in use on the Chicago, Milwaukee, and St. Paul railway, only a few months after the first test at Staten Island. One car on each train is furnished, it appears, with an inexpensive instrument, and induction is relied upon for carrying the electric current from this instrument through the air to the ordinary Morse wires at the side of the track. Construction trains on the St. Paul road are provided with these instruments and operators to work them. A construction train frequently has 70 or 80 labourers aboard, and must get out of the way of all regular traffic along the line. Accordingly, such a train has to be constantly moved on to sidings, in order to leave the road free for passenger and freight trains.

IF a fragment of potassium hydroxide be placed in some ferric-chloride, a few drops of bromine added, and if necessary gently heated, the mass dissolves in water, yielding a fine red solution of potassium ferrate resembling permanganate in its tinctorial power. A fine red solution of calcium ferrate is obtained by adding ferric chloride to bleaching powder and boiling with water. Manganous sulphate destroys the colour, and filtration through paper discharges it; barium chloride produces a purple precipitate of barium ferrate.

SCIENTIFIC SOCIETIES.

ROYAL METEOROLOGICAL SOCIETY.

THE first meeting of this Society for the present session was held on Wednesday evening, the 17th inst., at the Institution of Civil Engineers, 25, Great George-street, Mr. W. Ellis, F.R.A.S., President, in the chair.

The following gentlemen were elected Fellows—viz., Mr. B. A. Dobson, Mr. T. Gordon, Mr. H. Mantle, Rev. J. Watson, and Mr. F. Wright.

The papers read were:—

(1) "The Gale of Oct. 15th-16th, 1886, over the British Islands," by Mr. C. Harding, F.R.Met.Soc. The storm was of very exceptional strength in the west, south-west, and south of the British Islands; but the principal violence of the wind was limited to these parts, although the force of a gale was experienced generally over the whole kingdom. By the aid of ships' observations, the storm has been tracked a long distance out in the Atlantic. It appears to have been formed about 250 miles to the south-east of Newfoundland on the 12th, and was experienced by many ocean steamers on the 13th. When the first indication of approaching bad weather was shown by the barometer, and wind at our western outposts, the storm was about 500 miles to the west-south-west of the Irish coast, and was advancing at the rate of nearly 50 miles an hour. The centre of the disturbance struck the coast of Ireland at about 1 a.m. on the 15th, and by 8 a.m. was central over Ireland. The storm traversed the Irish Sea, and turned to the south-east over the western midlands and the southern counties of England, and its centre remained over the British Isles about 34 hours, having traversed about 500 miles. The storm afterwards crossed the English Channel into France, and subsequently again took a course to the north-eastwards, and finally broke up over Holland. In the centre of the storm the barometer fell to 28·5in.; but, as far as the action of the barometer was concerned, the principal feature of importance was the length of time that the readings remained low. At Geldeston, not far from Lowestoft, the mercury was below 29in. for 50 hours, and at Greenwich it was similarly low for 40 hours. The highest recorded hourly velocity of the wind was 78 miles from north-west at Scilly on the morning of the 16th, but, on due allowance being made for the squally character of the gale, it is estimated that in the squalls the velocity reached for a minute or so the hourly rate of about 120 miles, which is equivalent to a pressure of about 70lb. on the square foot. On the mainland the wind attained a velocity of about 60 miles an hour for a considerable time, but without question this velocity would be greatly exceeded in the squalls. In the eastern parts of England the velocity scarcely amounted to 30 miles in the hour. The force of the gale was very prolonged. At Scilly the velocity was above 30 miles an hour for 61 hours, and it was above 60 miles for 19 hours, whilst at Falmouth it was above 30 miles an hour for 52 hours. The erratic course of the storm and its slow rate of travel whilst over the British Islands were attributed to the presence of a barrier of high barometer readings over Northern Europe, and also to the attraction in a westerly direction owing to the great condensation and heavy rain in the rear of the storm. The rainfall in Ireland, Wales, and the south-west of England was exceptionally heavy. In the neighbourhood of Aberystwith the fall on the 15th was 3·83in., and at several stations the amount exceeded 2in. Serious floods occurred in many parts of the country. A most terrific sea was also experienced on the western coasts and in the English Channel, and the number of vessels to which casualties occurred on the British coasts during the gale tell their own tale of its violence. The total number of casualties to sailing vessels and steamships was 158, and among these were five sailing and one steam ship abandoned, five sailing and one steamship foundered, and 42 sailing and two steamships stranded. During the gale the lifeboats of the Royal National Lifeboat Institution were launched 14 times, and were instrumental in saving 36 lives.

(2) "The Climate of Carlisle," by Mr. T. G. Penn, F.R.Met.Soc. This is a discussion of the observations made at the Carlisle Cemetery. The mean temperature for the 23 years 1863-85 was 47·5°; the absolute highest was 95·0° on July 22nd, 1873, and the lowest 55° on January 16th, 1881. The mean annual rainfall was 29·80in.; the greatest monthly fall was 7·84in. in July, 1884; and the least 0·30in. in January, 1881. The average number of rainy days was 174.

(3) "Results of Hourly Readings Derived from a Redier Barograph at Geldeston, Norfolk, during the four years ending February, 1886," by Mr. E. T. Dowson, F.R.Met.Soc.

(4) "Results of Observations Taken at Delanasan, Bua, Fiji, during the five years ending December 31st, 1885, with a summary of results for the years previous," by Mr. R. L. Holmes F.R.Met.Soc.

SCIENTIFIC NEWS.

THE scheme for making a photographic atlas of the starry heavens, originally suggested by Dr. Gill to Admiral Mouchez, is taking a more definite character, and some time next spring accredited representatives of each nation willing to take a part in the work, will meet in Paris, probably. The idea is to make photographic charts of the heavens by the aid of telescopes of large aperture, and it is hinted that the atlas will contain, when completed, from 1,500 to 1,600 maps. A labour of such magnitude will, of necessity, take a long time; but now that the Brothers Henry, Mr. Common, and others have shown us what can be done by photography towards the advancement of astronomy, there will not be any lack of help in accomplishing the work. Prof. G. P. Bond may be said to have been the "father of stellar photography"; but the first photographic image of a star was, we believe, obtained by Mr. J. A. Whipple, under the direction of the late Prof. W. C. Bond, at Harvard College Observatory, Cambridge, Massachusetts, on July 17, 1850, when a sensitive daguerreotype plate was placed in the focus of the 15in. equatoreal, and the latter by means of the driving clock, was kept pointed to Vega (Alpha Lyræ). Nowadays we are far in advance of Mr. Whipple and his daguerreotype plate, but the record may be interesting to many.

Old pupils of the Royal Military Academy, Woolwich, will be sorry to hear of the death of John Fry Heather, M.A., for many years mathematical master at that establishment, and the author of several really valuable works which were issued in Weale's series. His "Drawing and Measuring Instruments," "Optical Instruments," and "Surveying and Astronomical Instruments" are probably the most useful works of the kind—certainly they are at the price charged for them.

The death is announced of Prof. Paul Morthier, of Neuchatel, a pupil of Oswald Heer and the founder of the Swiss Botanical Society. Dr. Morthier was an acknowledged authority on sponges.

The Royal Society medals have this year been awarded as follows:—The Copley Medal to Franz Ernst Neumann, of Königsberg (For. Mem.R.S.), for his researches in theoretical optics and electro-dynamics; the Davy Medal to Jean Charles Galissard de Marignac, of Geneva (For.Mem.R.S.), for his researches on atomic weights. Prof. Samuel P. Langley, of Allegheny, Pennsylvania, is awarded the Rumford Medal for his researches on the spectrum by means of the bolometer. Mr. Francis Galton and Prof. Guthrie Tait are nominated for the Royal Medals, the former eminent for his statistical inquiries into biological phenomena, and the latter for his various mathematical and physical researches. The medals will be presented at the anniversary meeting on Nov. 30.

From the report of the prize committee of the Royal Scottish Society of Arts we learn that Complimentary Keith medals have been awarded to Daniel William Kemp, J.P., Vice-President, for his "Unwritten Chapter in the Early History of the Iron Industry in Scotland: Iron Smelting in Sutherlandshire and the North of Scotland"; to Ernest William Moir, engineeer, Forth Bridge Works, for his paper on "The Pneumatic Caissons at the Forth Bridge Works"; and to William Hume, instrument maker, for his "Historical Demonstrations in Photography, with Illustrations and Specimens." The following prizes have been awarded:—1. To Nicol Arthur, shipbuilder, for his "Improved Machine for Bevelling Angle Iron" (the Keith prize, value £20); 2, to Walter Macdowall Hardie, printer, for his "Fluid Prisms of Novel Construction" (the Reid and Auld prize, value £10); 3, to John Greig, jun., engineer, for his "New Anti-friction Bearings, requiring no Oil or other Lubricant" (a Keith prize, value £10); 4, to James Watson Johns, law agent, for his "Automatic Shrapnell Shell" (a Brisbane prize, value £5); 5, to Alexander Fraser, M.A., optician, for his paper on "Recent Improvements on Freezing and other Microtomes" (a Hepburn prize, value £5); 6, to Alexander Fraser, M.A., optician, for his "Improved Centring and Focussing Nose-Piece (4523) and Self-Centring Turn-Table (4525) for Microscopes" (a Brisbane silver medal); 7, to John Miller Turnbull, photographic chemist, for his "Improved Sliding Nose-Piece and Adapter for the Microscope" (a Hepburn silver medal; 8, to Magnus Finlayson, carpenter, for his "Adaptation of Roller Gearing to Wringing Machines" (the Society's Honorary silver medal).

Steps are at length being taken at Cambridge University to provide Prof. Michael Foster with additional accommodation for the teaching of physiology. Dr. Foster found himself confronted this term with a class of nearly 100, who were to receive practical instruction in a room capable of containing about 80. He accordingly laid before the University the alternative of diminishing his class by about half, or providing fresh room. Naturally the latter alternative was adopted, and the Museum Syndicate has recommended the erection of a large lecture room on the east side of the Museum of Comparative Anatomy, at a cost of about £450.

Among the papers to be read during the session of the Society of Arts before Christmas, we note that Major-General Webber is to describe the use and manufacture of glow-lamps on Dec. 8, and on Dec. 15, Mr. J. B. Marsh will have something to say about "Cameo-cutting as an Occupation." Five courses of Cantor Lectures will be given during the session—viz., "Principles and Practice of Ornamental Design," by L. F. Day; "Diseases of Plants, with special reference to Agriculture and Forestry," by Dr. J. L. W. Thudichum; "Building Materials," by W. Y. Dent, F.C.S., F.I.C.; "Machines for Testing Materials, especially Iron and Steel," by Prof. W. C. Unwin; "The Structure of Textile Fibres," by Dr. F. H. Bowman, F.L.S. Two juvenile lectures on "Soap Bubbles" will be delivered by Prof. A. W. Reinold, F.R.S., on Jan. 5th and 12th next.

The City and Guilds Institute have arranged for a course of technical instruction for teachers of public elementary schools at the Central Institute, Exhibition-road, W. The course comprises lectures on the construction and manipulation of wood-working tools and practical instruction in the workshop. The applications for admission to this course far exceed in number what was anticipated, and the committee have accordingly arranged that the class shall meet three times a week instead of once.

"Degrees of heat" is a common error in the newspaper press; but "parallels of longitude" are the invention of a writer who endeavours to explain to his readers how a vessel sailing eastwardly gains on the sun.

The London Ornithological Society has signalised its first year of existence by holding a great cage-bird show in St. Stephen's-hall, at the Westminster Aquarium. It seems that for the high-sounding "ornithological" we should really read "bird fanciers." Let us hope for better things from the society in future.

An International Exhibition of Railway Appliances and Industries will be held in Paris from May to October of next year, when the jubilee of the fiftieth anniversary of the introduction of railways in France will be celebrated. The exhibition will comprise the various industrial and professional branches connected with railways, such as engineering and mechanics, locomotives, machinery, passenger carriages and freight trucks, hoisting and wrecking apparatus, apparatus for heating and lighting, apparatus for inter-communication, couplings, and other railway appliances, building, furnishing, and conveyance material, metallurgical and electrical apparatus, &c. At the same time an International Railway Congress will be held by delegates from railway companies, chambers of commerce, scientific and professional societies, for the discussion of important questions of management, working, maintenance, rolling-stock, security, traffic, &c.

An idea of the cost of electric light when supplied in the same way as companies distribute gas may be obtained from the schedule rates of the Edison Company at Middletown, Maryland. For a 10 candle-power lamp to burn all night in a factory they charge 5s. 7½d. per month, and for two 10-candle lamps in a private house one dollar (4s. 2d.) per month; but in the latter case the current is presumably switched off at 10 p.m. Five 10-candle lamps are supplied for 8s. 4d. a month, which would not be expensive, considering the advantages, if the current could be used during the whole of the dark hours.

Lecturing recently before the Edinburgh Health Society, Dr. Stevenson Macadam said that cocoa-nut oil soap contained about three-fourths of its entire weight of water, so that when his hearers purchased this soap they were paying for a good deal of water. Toilet soap was represented very well in what was known as "old brown Windsor soap," provided it was really old. In many cases transparent soap was not good, lots of sugar being added to produce the transparency. Good yellow soap was usually better than toilet soap. There was one which he would exempt from the rest of soaps prepared roughly, or which did not possess the quality attributed to them, and that was an over-fatted soap which contained an excess of fatty matter, so that it could be used with great advantage on tender skins. The price of this soap, however, he thought, was much too high. He deprecated very much the use of soap powders, and producing a 6d. packet of this compound, on which a label was affixed stating that while possessing every beneficial quality, it had not the pernicious effects of washing soda—he observed that he had examined the packet and found that it was nothing but washing soda—2lb. of which could be bought for 1½d. He excepted borax powder from this catalogue, remarking that a little of it might be found beneficial for washing purposes. In conclusion, he showed by experiment that bleaching powders, while of assistance to cleansing, destroyed coloured fabrics, and also destroyed the fibre.

A Greifswald correspondent reports to the *Kölnische Zeitung* a beautiful lunar phenomenon seen there some evenings since. The crescent clearly defined was in the south-western heavens, when suddenly at its right side an enlarged reflection of the crescent appeared, just as sharply defined, and shining as clearly as the original crescent which it gradually seemed to embrace. After some minutes there appeared on the left side a further reflection of this original image, but less bright and distinct. Both images remained visible for a considerable time, and then faded gradually away with the deepening darkness, leaving the crescent moon shining brightly as before.

The Belgian Société des Ingénieurs et des Industries will open on Dec. 3rd at the Brussels Bourse an exhibition of the practical applications of indiarubber, guttapercha, and similar substances. Lectures will be given during the exhibition.

The San Francisco Microscopical Social held its annual reception on October 16 last, and a very enjoyable evening was spent by the members and their friends, no fewer than forty-five microscopes being tabled,—the largest number ever exhibited at one time on the Pacific Coast. At the regular meeting on Oct. 27, Dr. Harkness reported that the "reception" was unsurpassed in three respects—viz., the quality of the instruments used, the skill shown in regard to methods of illumination, and the very attractive selection of objects shown. The President exhibited the new "Zeiss" microscope ordered some months ago. The workmanship of the stand was critically examined by the members, and was greatly admired. The instrument was specially constructed for biological research, and is equipped with a complete outfit of accessories. The battery of objectives contains two specimens of the recently perfected "apochromatic" lenses, constructed of the new optical glass made under the direction of Prof. Abbe and Dr. Schott. These two lenses are of 1-12in. and 1-18in. focal distance respectively, and their performance over some slides of pathogenic bacilli left nothing to be desired. Their definition is very crisp, and both the spherical and chromatic aberrations have evidently been corrected to a degree closely approaching absolute perfection. No trial of their resolving powers has yet been made here, but it will soon be done. Both lenses have ample working distance, that of the 1-18, being 2mm., or nearly a twelfth of an inch. They are also provided with what are termed "compensating oculars." These have been specially constructed with a view to correcting the colour-aberration caused by the

front lens of each objective, this front glass being a single lens and therefore unachromatic.

Mr. C. E. Stretton, the Consulting Engineer A.S.R.S., has lately taken a northern lecturing tour in the interests of the society, and given lectures on locomotive engineering and railway safety at Edinburgh, Glasgow, Carlisle, Liverpool, Leeds, Leicester, and Birmingham.

LETTERS TO THE EDITOR.

[*We do not hold ourselves responsible for the opinions of our correspondents. The editor respectfully requests that all communications should be drawn up as briefly as possible.*]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, *332, Strand, W.C.*

All Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

**** In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks, a vice from whence great inconveniences derive their original."—*Montaigne's Essays.*

SIRIUS.

[26520.]—THERE must be some mistake, probably in the printing, in the mass of the Sirius system, as obtained by Mr. Gore, given on page 258 of the ENGLISH MECHANIC. Auwers found with a Gyldén's parallax of 0·193", and his own orbit period 49·4 years, that the mass of Sirius was equal to 13¾ times the sun's mass, that of the companion being equivalent to 6¾ suns, the mean distance being 13 times the earth's orbit. Gyldén's value was obtained from a discussion of Maclear's Cape declinations, and is, therefore, an *absolute* parallax. Gill found from heliometer measures at the Cape that the parallax of Sirius relative to a star of the 7th magnitude was 0·370"—Elkin finding 0·47" and 0·39" with the same instrument—a small heliometer of 4in. aperture. Of course, to get the absolute parallax from these figures the actual parallax of the small star observed, whatever such parallax may be, must be added. The distances of the comparison stars were, however, so large—in Gill's case 1° 1', in Elkin's case 1° 24'—that errors of considerable magnitude may very conceivably have arisen. Henderson found from his own meridian observations a parallax of 0·23"; Abbe, from Maclear's later declinations, 0·27"—both being, of course, absolute values. The report in the ENGLISH MECHANIC does not mention the parallax employed by Mr. Gore. Elkin's of α Centauri is relative; he found a much smaller one on discussing Henderson's declinations.

Nov. 21. **H. Sadler.**

FINLAY'S COMET.

[26521.]—FINLAY'S comet was observed here by my assistant at 6.30 p.m., Nov. 16. Position R.A. 20h. 3m.; Decl. 23° 9' S. The comet is a bright nebulous body, with a very condensed centre and no tail. Instrument used, 6in. o.g., power 25.

C. E. Peek, M.A.

Rousdon Observatory, Lyme Regis, Nov. 21.

IS JUPITER SELF-LUMINOUS?

[26522.]—PERHAPS some of the readers of the "E. M." may be willing to explain the value of the comparisons made by Mr. Biggs as set out in the extract from his paper ("E. M.," Nov. 19, page 255). At first blush they do not seem to prove more than what has never been questioned—that Jupiter is brighter than ruddy Mars. One has always been led to think that the surface of Mars was not possessed of good reflective powers. Redness in light one associates with impaired brilliancy. The difference between the apparent sizes of Jupiter and Mars have also to be reckoned with, and more complicated still must be a comparison of the white spots, or polar snow, on Mars, with the surface of Jupiter, if the comparison is to be anyway accurate and, consequently, useful as evidence. These and other points leave one as far as ever from the impression of there being as yet any known reason, let alone proof, that Jupiter shines by any other than borrowed light. Questions of interest might be asked as to the relative reflective powers of the four satellites, and the relative density of their atmospheric surroundings. The bright planets, Venus and Jupiter, I believe, are considered to have dense vaporous envelopes, while from observations and drawings it would seem that the eyes of our astronomers are able to penetrate the atmospheric surroundings of Mars.

Since jotting down the above difficulties, I have found a paragraph in Lardner's "Handbook of Astronomy" (fourth edition, by Mr. Dunkin, F.R.A.S., page 234) bearing directly on the subject. It would be interesting, I think (if space will admit) to insert the paragraph:—

"The apparent splendour of a planet depends conjointly on the apparent area of its disc, and the intensity of the illumination of its surface. The area of the disc is proportional to the square of its apparent diameter, and the illumination of the surface depends conjointly on the intensity of the sun's light at the planet, and the reflecting power of the surface. On comparing Mars with Jupiter, we find the apparent splendour of the latter planet much greater than it ought to be, as compared with the former, if the reflecting power of these surfaces were the same, and are, consequently, compelled to conclude that the surface of Mars is endowed with some physical quality, in virtue of which it absorbs much more of the solar light incident upon it than that of Jupiter does. When the apparent diameter of the latter is twice that of the former, its apparent area is fourfold that of the former. But the intensity of the solar light at Jupiter is at the same time about thirteen times less than at Mars; and if the reflective power of the surfaces were equal, the apparent splendour of Mars would be more than three times that of Jupiter. The reflective power must, therefore, be less in a sufficient proportion to explain the inferior splendour of Mars, unless, indeed, the very improbable supposition be admitted that there may be a source of light in Jupiter independent of solar illumination."

Hendon, Nov. 20. **P. E. Duke.**

METEOR.

[26523.]—WHILE observing on Wednesday, the 17th, at 7.15 p.m., I was startled by the sudden apparition of a brilliant meteor or fireball. It appeared to commence its course in the neighbourhood of Andromeda, and after crossing the sky at a distance of about 20° from the zenith in a north-westerly direction, finally disappeared in Cygnus. Its brilliance was many times greater than Venus when at her brightest, and the nucleus was followed by a luminous trail. Of the precise position and brilliance of the celestial visitor I could not be absolutely certain, as the part of the sky in which it appeared was, to my great annoyance, just then veiled by a passing cloud of mist; but I believe the above rough estimates are, as far as they go, accurate.

Coming, as it did, from the direction of the constellation Andromeda, had its appearance been a few days later, I should have concluded it to be a stray remnant of the unfortunate comet Biela, which favoured us last year with so brilliant a display of its former substance in the shape of a shower of "falling stars."

Handsworth, Birmingham. **B. A.**

[26524.]—A SPLENDID fireball was seen here on November 17th, 7h. 12m. G.M.T. Owing to trees, I could only get a rough determination of its apparent path, which was:—

	α	δ
From	10°	S. 8°
To	320°	S. 12°

Its diameter was fully one-third that of the moon, and it lit up the surrounding sky in a beautiful manner. It was followed by a short train, and its colour was bluish-green. Its disappearance was not accompanied by any detonation. Duration, three seconds.

Crawshawbooth. **C. L. Tweedale.**

ABNORMAL TELESCOPIC DEFINITION.

[26525.]—I AM much obliged to Mr. Franks (letter 26444) for the reference to the *Phil. Trans.* I had referred, however, to that volume before, as it contains H's observations on telescopic definition. There is nothing whatever said there about the *triangularity* of star discs. I have read many times with attention all that Sir W. Herschel has written in the *Phil. Trans.*, and I have also been over many of his MSS. works with great care; but I never remember having seen any reference to this in any of his writings. **H. Sadler.**

EGYPTOLOGY.

[26526.]—"PONTO" (26542) must remember that the "whole earth" is of exactly the same size as when Genesis was written. If the writer only knew a part, and called it the whole, it shows he was imperfectly informed. Whatever Genesis may be responsible for, there were multitudes of seas, islands, mountains, &c., before the time of the deluge, or the advent of man, as geology amply proves. During that long period we find innumerable traces of great rivers which could not be fed with water if abundance of rain did not fall. Even in old rocks, as Geikie in his "Textbook of Geology" says, at page 485, "The familiar effects of a heavy shower upon a surface of moist sand or mud may be witnessed among rocks, even as old as parts of the Cambrian system." I am afraid "Ponto's" theory is not tenable, as it appears to ignore the reliable information derived from geology, which proves that the surface of the world has changed over and over again, and that all the time sunshine, rain, frost, and storms were as now.

As to "E. L. G.'s" remarks (26510), I must say that the expression "Abraham was gathered to his fathers," may be taken in more ways than one. The books it occurs in are, by "E. L. G.'s" showing, much later than the time of Abraham or Moses, so the phrase may be late. But then it may simply mean that he had gone to the grave. We know that in late time "the bosom of Abraham" meant (according to Josephus) "A subterraneous region where the light of this world does not shine." Is that "E. L. G.'s" opinion?

The Sadducees could not hold any such view, and unless it can be pointed out in the official law that some promise or threat regarding the next world is to be found, we cannot set aside the great omission by such arguments as "E. L. G." offers. His curious remark about Italians is entirely beside the point. If all Englishmen had spoken and written in Italian at the time of Lord Beaconsfield's grandfather, I rather think Italian would now enter largely into the English language.

The stories of Abraham and Isaac referred to appear to be the same, with trifling differences.

"E. L. G." should quote Scripture with more care. He says, "It is never said of them; but only of Abraham that God blessed him in all things." He forgets Gen. xxvi. where God says to Isaac, "Sojourn in this land (Canaan), and I will be with thee, and I will bless thee; for unto thee and unto thy seed I will give all these countries." It may be the story of Abraham told under the name of Isaac; but "E. L. G." should not forget it.

His answer about the name Jehovah is curiously weak, as is also that of "Ramases." "E. L. G." says it was most natural for God to say to Moses, "By my name Jehovah was I not known," and then for Moses to sit down and write the words of Eve, "I have gotten a man from Jehovah," and to put the same name in the mouths of the particular persons named as those who did not know it. Such conduct does not seem to me to be reasonable or likely, and if really used deliberately, how can we rely on any word or name? It did not seem easily explainable or natural to the translators of the English Bible, or the Roman Catholic translators of the Douay Bible, for they both omitted the name Jehovah, and used for it the words "the Lord," apparently wishing to hide the fact from their flocks.

I cannot agree with "Ramases" that the theory of two writers, at least, being responsible for Genesis *is upset*. If so, will he kindly give the particulars on which he relies? It is usual for writers, especially theological ones, to suppose that their opponent's arguments are upset. Copernicus and Galileo were both supposed to be put down, and so were the geologists till lately, when it was found they had won the day. I have asked "Ramases" for particulars often, and do not get them.

The value of Josephus is not as great to orthodox writers as "E. L. G." supposes, as Josephus considers the Shepherd Kings to be the ancient Jews, which, if true, proves the account in Exodus to be quite wrong.

There is no really good testimony to the so-called historical Flood. The Egyptians knew nothing of it. The Assyrians had such a story, but as they were intimately related to the Hebrews, that is not wonderful. What is odd is that the two accounts differ so much. The Assyrian story makes the Flood last for seven days only, while that in Genesis lasts for a year or more, which, if true, would have killed nearly all trees and plants, as well as all animals not contained (together with their food for a year) in an ark the size of the Great Eastern steamship.

The reason why stories of floods in a few old nations occur is that the surface of the earth has been over and over again under the sea, and that fossil sea shells occur in many places, though how they got there was not known till quite recently. They are of immense antiquity, but used to be supposed to be deposited by the Flood about 2,000 years B.C.

Again, many seas—such as the Caspian Sea—are shrinking. It covers much less ground than it used to do, so that the surface of much land near it shows the action of water at no great distance from the historic period. In old times all remarkable occurrences were ascribed to the direct personal action of God, wishing to speak directly to man through them; but now such things are supposed to be merely specimens of the action of God's general law and to have no moral meaning. We know that by the action of law the present surface of the earth, its plains and valleys, its hills and mountains, were many times below the surface of the sea—so need no miraculous flood to

explain the marks of water or the presence of shells; neither need we suppose any mass of water was added to the world 4,000 years ago. Where "E. L. G." supposes it came from or went to I cannot imagine. If marvellous miracles are easily accepted, anything may be so proved; but more evidence is needed to prove them than is forthcoming. Such wonders generally occur in remote places and in uncritical ages; never in our own experience, or in presence of a critical audience, who would cross-examine.

The same remarks apply to the assertion that the sun stood still. "Ramases" says that in reality it was the earth that went slow; but, in saying so, he overlooks the plain words and evident meaning of the writer. Joshua spoke to the sun, and also to the moon, and both obeyed him. If the earth went slow, it would not have affected the moon. The stoppage of the moon was not necessary for the business in hand, and yet required the suspension of the law of attraction, as if it stopped it would have come down plump on to the earth if that law had not been suspended. It is singularly improbable that such a miracle should occur to enable the Jews to exterminate some of the people of Canaan, whose land they wanted to take; and, moreover, it is unaccountable how, with the aid of such great miraculous power, they conquered the land so imperfectly. The Jebusites and others were too many for them; and concerning the Jebusites, it is written in Joshua xv. 63 that "the children of Judah could not drive them out."

If such a marvellous miracle really happened, it would be known and noted all over the world, and would settle the question of date at once. This would especially be so in Egypt and Babylonia—both old States, where the study of the heavenly bodies was carefully carried on. There is no such record known in either of them.

These great miracles are also discredited by the fact that the early Jews seemed to be little affected by them, lapsing over and over again into idolatry; yet the same nation became steadily monotheistic when once the story was well written down and taught to them when young, after the Captivity.

They seem not to have relied on the so-called facts when they saw them—at least, the children did not believe what their fathers are said to have said; but they firmly believed in it as soon as it was written down. As to "Dens's" remark (26514) about Samuel, he will find it hard to prove he wrote Deuteronomy, or various parts of the other books, such as Gen. xxxv., where kings are promised as a reward to Jacob. Compare that with Samuel viii., where we find kings looked on with horror, their rights and powers being opposed to those of God. The Elohim documents are probably of about Samuel's time; but the Jehovistic ones are more likely to be of Solomon's, as they were written after the expulsion of the Canaanites, as is shown from Gen. xii. 6, and xiii. 7, "The Canaanite was *then* in the land"; "The Canaanite and Perizzite dwelt *then* in the land." And also after Saul's victory over Agag, Numbers xxiv. 7, "and his king shall be higher than Agag."

It must not be supposed that because Genesis is first in order at present that it was written first. Some parts *may* have been; but certainly not the book as it stands.

I cannot see why the Pentateuch is implied because Samuel was high priest and judge. Priests and judges are by no means uncommon amongst people who know not the Pentateuch. Moses probably wrote the Ten Commandments in a short way on stone, urged the worship of one God on an idolatrous people, and left general traditions, which later writers took up and added to, considering they were thereby carrying out his intentions. Little can be known with certainty as to what Moses did or said; but I cannot imagine that the wild tribes—idol worshippers mostly—exhibited to us in Judges ever had been in the highly-civilised condition implied by the Pentateuch. That a people should be at one time noble theists, with a clear law, good literature, and the ever ready help of tremendous miracles, and yet should immediately descend to the condition of a loosely-knit collection of wild idolatrous tribes, I cannot suppose. It is more likely that these highly-coloured pictures of antiquity were painted to urge them to improve, and aim at theism and virtue rather than to represent what had actually occurred. **Memnon.**

EGYPTOLOGY, &c.

[26527.]—In fourth line of p. 264 the omission of a short pronoun has made me appear very foolish. What I asked "Memnon" in that clause was whether a patriarch "losing his wife, and her being taken into the king's harem," was "the same as having it accidentally discovered that she was not his sister." The two ways Abraham and Isaac got into scrapes by the same fault, in ch. xii. and xxvi., are so entirely unlike that no reader would ever have called them "ascription of the same story"; but for a confusing of both with the unlucky ch. xx., that I said gives us the utmost measure of error we detect in these writings honestly scrutinised. We have no ground to suspect any deed or word is ascribed wrongly to the Almighty. In ch. xii. it was simply said that He "plagued Pharaoh and his house with great plagues," which implies it was somehow revealed who sent the misfortunes, and why. Now, ch. xx. seems a fuller account of the same event, though misdated and ascribed to another king and place. The dream there related was doubtless a real one, divinely sent, though not to Abimelech, but to Pharaoh 25 years earlier. Both Pharaohs of Genesis were plainly of the Hyksos dynasty, Asiatic, and probably Shemite, no idolators, and nearly as divinely honoured as the Hebrew patriarchs. Joseph's Pharaoh was the most so of any monarch hitherto, because he established socialism; and xlvii. 26 assures us that socialism succeeded for at least six or seven centuries, if we allow the book to date from when it professes to have been written (or professes to have been "forged," if "Dens" will have this word so applied); but if it is all preternatural and mystic, and anything but what it seems or claims to be, it cannot assure us of this, or anything else of use.

Having quoted "Dens," let me apply his own rule about credible miracles; that "they just supply the exact amount of help for the work to be done and then cease." The chief work in the rout of these Amorites, verse 11 says, was done by hail in the night. "They were more which died of hailstones than they whom the children of Israel slew with the sword." If the hail needed sunlight for its work, then the sun plainly did not stay long enough. But if "Dens" will have the hailstorm to be mythic, and that the work was mainly done by the Israelites, he merely contradicts the non-miraculous part of the story to bolster up the other, or rather abandons Scripture to support the inspiration of Jasher, a book never accounted Scripture, and now lost. That true miracles are "in strict harmony with the narrative" is just the reason why this, being in no harmony, but flatly inconsistent therewith, must be rejected, though the son of Sirach, and apparently even the LXX. misinterpreted it, and our Revisers (with a big R, as they always give themselves) dare not differ. No New Testament allusion to it occurs, even in Hebrews xi., where it seems as worthy of mention as stopping the mouths of lions, waxing valiant in fight, &c. And when Christ told men to be as their Father, who maketh his sun to shine on the just and unjust, why did none object, and ask, Nay, Rabbi; if the Lord had always so ruled His sun, even in Father Joshua's time, should we have had the Amorites' land?

As for topography, it is so extremely doubtful whether any other of the places than Gibeon can be identified, that whether Joshua marched 20 miles or 60 is unknowable. But, in this matter, neither "Ramases" nor "Dens" has searched Scripture enough, though their main fault, and that of us all in these discussions, is insisting too much that "the Bible says" this or that, and attending far too little to what the facts of nature say. This applies equally to the Bible's friends and enemies. The principle, barely 40 years old, if so many, that the more a thing opposes Scripture, the more likely to be valuable, is not a safe one. Poor Sir C. Lyell, who originated it, found it pay commercially; but all real progress in geology since then has been by foreigners, who were uninfluenced by it. All the British views that, in the absence of a Bible to kick, would have occurred to nobody, seem sterile or getting disproved.

Meanwhile the old and opposite misuse of Bible still clings to us non-Lyellists. Though nobody dreams now, like the Mediævals or Burnet, of the "Theory of the Earth," that science can be got out of Scripture alone, we get notions that some things the Bible is vulgarly supposed to say may help scientific theory, or even that versions thereof for us non-Hebraists may do so. Thus I got misled, though not so much as "Ponto" and the Duke of Argyll, and nearly all reasoners about the Deluge are still, when treating that event some years ago, in Vol. XVII. I then drew from the clause in Gen. vii. 11 that "all the fountains of the great deep were broken up," a notion of large seismic disturbance of the earth's crust, leading to submergence of lands, and their remaining submerged, mostly even longer than Noah was afloat. But the late Prof. Challis, a Hebraist as well as astronomer, did not take, in this text, the abyss (or the boundless) for the earth's interior, nor the ocean, but for the sky, and understood the clause merely as parallel to what follows, that cataracts fell from heaven. We have no warranty, I now think, for supposing any submergence (a non-Biblical word) of places now above sea-level; though large previously habitable lowlands became and continue sea-beds, as the English and Irish Channels, German sea, much of the Mediterranean, &c., not by sinking, but by the addition of so much water to our globe as to raise the ocean level about 100 fathoms. The time when all "hills under the whole heaven were covered," I now think was only during the actual downpour, which all fell in some hours, at the most in less than the week remembered in the Assyrian tablet. There was no time that our hills were covered with *standing* water, but only with rushing torrents. Though on all land (that was then land) new valleys were scooped out, and vast gravel-beds laid, the crust was not moved up or down, of most continents, or certainly not of Western Europe. All our strata kept their form unmoved. Whether there was submergence anywhere, depends on whether Armenia and Northern Syria were land or sea before the catastrophe. They may, for aught that travellers have yet said of them, have been a sea-bed that it caused to be, in a few months, upheaved for the first time. But if they are ancient land, that part of the crust sank and rose again, as we formerly fancied all continents had done. Noah's voyage was so contrived, unknown to him, as to give the whole vegetable world (and the few wild animals that drift-timber and other natural accidents saved) twelve clear months' start of him and his cattle. The upheaving Ararat, newest mountain, hoisted them in their prison into a pure air, above the clouds and the pestilential miasma of the rotting world, under the hottest summer it can have known; and then they descended into plains duly prepared for them.

Poor Darwin, the most famed—Evolution Darwin—contrived so well to forget the following bit of his early travels, not reprinted, I believe, since 1845, that for such youths as "Memnon" it is needed:—

"It is impossible to reflect on the changed state of this [American] Continent without the deepest astonishment. Formerly it must have swarmed with great monsters; now we find mere pigmies compared with the antecedent allied races. If Buffon had known of the gigantic sloth and armadillo-like animals, and of the lost pachyderms, he might have said, with a greater semblance of truth, that the creative force in America had lost its power, rather than that it had never had great vigour. The greater number, if not all, of the extinct quadrupeds lived at a late period, contemporaries of the existing sea shells. Since they lived no very great change in the form of the land can have taken place. What, then, has exterminated so many species and whole genera? The mind at first is irresistibly hurried into the belief of some great catastrophe; but thus to destroy animals, both large and small, in Southern Patagonia, in Brazil, on the Cordillera of Peru, in North America, up to Behring Straits, we must shake the entire framework of the globe. It appears from the character of the fossils in Europe, Asia, Australia, and in North and South America, that those conditions which favour the life of the larger quadrupeds were lately co-extensive with the world. It could hardly have been a change of temperature which, at about the same time destroyed the inhabitants of tropical, temperate, and arctic latitudes on both sides of the globe. Did man at his first inroad into South America, destroy, as has been suggested, the unwieldy megatherium and other edentates? We must, at least, look to some other cause for the destruction of the little Tucutuco, and of the many fossil mice, and other small quadrupeds in Brazil. No one will imagine that a drought, even far severer than those which cause such losses in the provinces of La Plata, could destroy every individual of every species, from Southern Patagonia to Behring Straits. What shall we say of the extinction of the horse? Did those plains fail of pasture which have since been overrun by thousands and hundreds of thousands of the descendants of the stock introduced by the Spaniards? Certainly, no fact in the long history of the world is so startling as . . . . [this] wide . . . . extermination of its [late] inhabitants."

I alter a word or two in that last clause, which ran, "the wide and repeated extermination of its inhabitants." But where had he found, or even hinted at, any other extermination for this recent one to *repeat*? No fact can be "startling" but one that we find as a fact; not things, "repeated" or not, that you infer to have perhaps happened because this did once! **E. L. G.**

[26528.]—In reply to "Memnon" (26513) respecting the testimony of the book of Joshua to the authenticity of the Pentateuch, "Memnon" says: "As for Joshua quoting Deuteronomy, that is rather against the age of the former, as the latter is supposed to be the book found in the Temple in the time of Joshua (Josiah?) by Hilkiah—who, it is likely, wrote it and placed it there." I again say, suppose "Memnon" offered a statement like this built upon "suppose," and "likely," as evidence in a court of justice, what would be thought of it?

When "Memnon" gave his list of great Egyptologists, he (very rightly) based them on Manetho, whom, as a matter of fact, they followed as regards great lengths of time. But what is the value of these authorities? Take the greatest of them, Baron Bunsen. With him, reigns and dynasties are made successive or contemporaneous on no internal or external evidence; kings are transplanted from one dynasty to another, and the result is an

arrangement which not only was never registered in an Egyptian temple, but never entered the thoughts of any Egyptian writer—a "German Manetho" in short, with whom it has been justly remarked that "names go for little and numbers for nothing." And nothing is more common with these great Egyptologists than to arrange the hieroglyphics so as to produce a different name or to slide a thousand years up or down the scale of time, for no other reason than to fit it better into their hypothesis. While quoting authorities in this connection, it should be mentioned that Champollion considered that he had demonstrated that no existing monument is older than 2,200 B.C.

The remaining portion of "Memnon's" letter is devoted to the argument derived from the length of time demanded, according to certain authorities, for the rise of Egypt and the erection of its great monuments. Here a great fallacy has been erected by following the imagination and neglecting the facts of nature and of history. Darwin and Spencer have shown that while for very long periods of time small changes have frequently been going forward among organisms, yet the vast variations have come to pass in relatively short periods of time. History exhibits the same phenomena. Nations rise rapidly, and their most important works are compressed into a relatively short space of time. Rome was changed from mud to marble in a single emperor's reign. Look at the signs of these present times. Men have been dabbling in science since the Great Pyramid was laid four square, yet more progress has been made in the last thirty years than in all the centuries which have gone before.

Thus, then, the facts of nature and of history are on the side of the Pentateuch, and they set aside entirely these *conjectures* of men.

As to Moses' alleged ignorance of Menes, I would ask what was there to know? since of that dynasty there are no monuments. As to the record of the death of the great Lawgiver, it could very well have been written by a scribe employed by him to write the book of Deuteronomy. Except to prejudice there is no difficulty here whatever.

To say that kings promised to Jacob is a proof of the lateness of the book of Genesis, is to beg the question in dispute.

Finally, be it remembered that I have given right evidence, traditional and historic, for the authenticity of the Pentateuch. "Memnon" has none whatever to give; he relies only upon objections, and these objections are either wholly without proof, or are easily shown to consist perfectly with the statements against which they are alleged.

Nov. 19. **Ramases.**

HOW A BOY MAY RAISE A SOLID TON WEIGHT WITHOUT MACHINERY.

[26529.]—IF "Nun. Dor." had read my letter, p. 195, carefully, he surely would have perceived that the boy must be on deck, for he has to pull each yarn separately "upwards," and make fast to a nail driven either into the combings of the hold or the deck. Each yarn on being stretched with a strain of 10lb. and fastened to a separate nail, lightens the weight or pressure upon the bottom of the hold, until it becomes suspended.

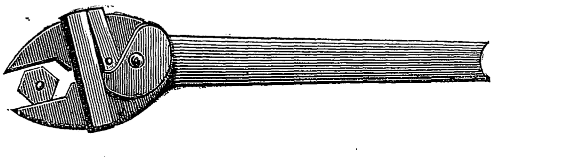
My demonstration consisted in pulling up a 7lb. weight, by using several lengths of cotton attached to it, either of which would have broken if pulled with a greater force than a quarter of a pound. By increasing the number of lengths of cotton, seven, or even seventy tons, may be raised in the same manner, and by a boy.

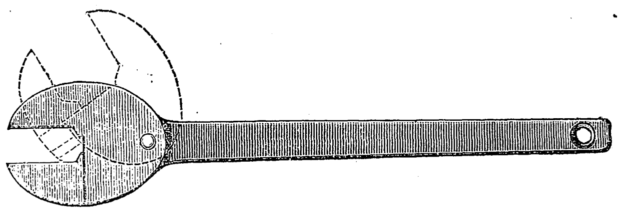
I will leave "Nun. Dor." to work out the little banter problems, of making 13in. to a foot, and carrying himself about in his own tub.

B. R.

INCANDESCENT LAMPS—TO MR. SHIPPEY.

[26530.]—I WAS very pleased to see Mr. Shippey's letter in the "E. M." for the 19th inst. (p. 266), and should be very glad if he will kindly enlighten me on the two or three points specified below. (1) Ought incandescent lamps to be raised until they scintillate, or appear to be surrounded with rays of light when observing them at some little distance from lamp? Any information as to the appearances indicating when a lamp is giving as much light as it will safely bear would, I think, be acceptable to many readers of "Ours," as a goodly number of amateur dabblers with the electric light have no means of measuring the current given by the dynamo employed. (2) In a 12v. l.r. lamp which I bought some little time ago, I notice that the carbon filament is very much shorter than in some 25v. lamps that I have; both lamps are called 10c.p. I, unfortunately, burned off the 12v. lamp soon after getting it, so had no opportunity of comparing the light given by it with the light given by the lamp with the longer filament. Do these l.r. lamps give as much light as the lamps with longer filaments of the some denomination? If so, please explain the reason why. **Iota.**





SPANNERS.

[25531.]—REFERRING to your correspondent's letter, "C. H. C.," on the subject of spanners, permit us to say that the spanner described is well known to us, but is, we think, far excelled by the Schwartzkopf spanner, sketches of which we inclose herewith.

This spanner is entirely self-adjusting, is made of wrought-iron throughout, in three sizes, taking in nuts from $\frac{7}{16}$in. up to $2\frac{5}{8}$in., and is, in our opinion, by far the most powerful spanner in existence.

Selig, Sonnenthal, & Co.

[26532.]—IF "C. H. C." (p. 263) will refer to p. 62, No. 653, he will find a description of the adjustable spanner he illustrates as "an excellent French one." In No. 653 this identical spanner is stated to have been forwarded by Messrs. Rawkins and Co., of Bury St. Edmunds, and it is mentioned as likely to become a favourite with bicyclists and others. **Nun. Dor.**

INVENTIONS AND PATENT LAW.

[26533.]—IN your number of 19th November, p. 255, you give an extract from an American (Mr. T. Pray, jun., of Hartford, Connecticut) which bears on Mr. T. Fletcher's invention, "A New Departure in Water Heating," described in "Ours" of No. 1108. Now, T. Pray, jun., is quite right to write and say that he had anticipated Mr. Fletcher in his idea, only the remark naturally occurs to one, "Why did T. Pray, jun., hide his light under a bushel?" But the sting of T. Pray, jun.'s, letter is that he claims to destroy T. Fletcher's right to a patent.

I have heard that such a thing as a discovery in America *may* prevent an *American* patent, though I do not believe it goes so far as to enable a man to make an experiment, never disclose it, and then prevent anyone else from getting an *American* patent. But what I am interested in is the English law and the right to an English patent, and I unhesitatingly affirm that what was done in America, secretly or openly, will not take away the right to an English patent if what was done even openly was not known by books or newspapers in England. This much in justice to Mr. Fletcher.

R. S. T.

THE DANIELL CELL FOR ELECTRIC LIGHTING—WONDERFUL LAMPS.

[26534.]—THE truth concerning these so-called Wonderful Lamps which I gave last week has caused Shippey Bros. considerable alarm, judging from their very hasty reply in this week's issue of "Ours." In their advertisement, which has now appeared for some time, they tacitly endorse Mr. Bottone's description, that it is a lamp giving a light of 5c.p., requiring 4/7 ampère, with an E.M.F. at the terminals of the lamp of 4 volts. I wrote to Mr. Bottone as soon as his communication appeared to know if this was really the case. He replied substantially confirming it. I could hardly credit it, though reluctant to doubt his bona fides. Shortly afterwards Shippey Bros'. advertisement appeared as the makers of this lamp, "as described by Mr. Bottone." Whereas, in fact, it is nothing of the kind. I procured two of them to test them for myself. In order to be quite certain, I sent one to an electrician not unknown in these columns, and his measurement of the r. *cold* agreed with mine. If the lamps had the wonderful properties claimed, electric lighting would advance by "leaps and bounds." When a firm or an individual advertises a certain article which is claimed to be so much superior to anything else, and it turns out to be decidedly not so, the transaction is, to say the least, not creditable.

The E.M.F. of 15 Daniell cells in series is 16 volts. If this battery would light eight 18 volts standard 10c.p., then "may I be there to see." They are probably another variety of the Wonderful. To show that I am not "prejudiced," I should advise "Nemo" to adopt them in preference to those I specified. It would be advisable to have them on trial.

If Shippey Bros. had read my letter with a little more attention, they would have discovered that I advised the overrunning of lamps only when used with a battery with zinc as the postive element. Zinc here occupies the same relative position as the coal in the furnace of a steam boiler, and being about 100 times as costly is more to be studied than a long life of the lamp. As a corollary of this, the cheaper the lamps become the more overrun it will be economical to use them. Messrs. Shippey's condemnation of this overrunning lamps is somewhat curious, considering that Mr. A. Shippey advocated such a course in the *Electrical Review* some months back, and actually confirmed it in a reply to an inquiry I addressed to him, asking if the extraordinary efficiency of the Wonderful lamp was to be attributed to this method of using them. He replied that I was quite right in assuming that to be his theory, which was shared by Mr. Preece and other eminent electricians. I also asked what was the life of the lamps subjected to this strain; he replied that with care they would last 500 or 600 hours.

As to the formula, "We simply challenge and defy," I will simply (not challenge or defy) say that when the resistance of an incandescent lamp is mentioned it is usually understood to be the R. *hot*. (In Shippey's 6 volt lamps the resistance hot is about 2·5 ohms.) A 5c.p. lamp of 4·5 ohms hot requiring an E.M.F. of 6 volts, would have an efficiency of 1·59 watts per candle. Try again, Shippey Bros.

The lamps I commented on were not coupled up to the 15 Daniell cells, and only Shippey Bros'. imagination has conjured up such a dreadful proceeding. If they had been, probably their duration would have been 20 minutes or less, and a light of perhaps 50c.p. The explosion I referred to was of the wonderfulness, not of the material lamps; these, I am happy to say, are as yet intact. I shall run them up to my standard, and let "Ours" know the result.

I will reply to "Electra" if possible next week.

F. L. Striffler.

TRICYCLING MATTERS.

[26535.]—IN reference to John Bell's communication last week, I would state my experience on two points—viz., the steering handles and the speed.

I have had, in all, six tricycles during the past seven years. My first mount was a "Challenge," by Singer, with what practically amounted to "bicycle steering," seeing that both hands were employed on the handles that communicated directly with two combined steering wheels. My next four mounts, four different kinds, had spade handles; but, to my joy, I have thankfully returned to a bicycle-steering machine, which is so much more pleasant to use, in my estimation (and my experience has been varied).

Now, as to speed-gearing, your correspondent finds his present gear unsuitable to both conditions of hilly and level ground. Let him adopt the Crypto gear, and he will find it all that he can possibly desire. My present machine is fitted with it, and I cannot speak too highly in its favour. I never spent £6 more satisfactorily to myself than in its purchase. I need hardly say that I have no connection with the Crypto firm, being merely a **Country Parson.**

[26536.]—I AM obliged to C. Leni for his invitation to call and take a ride with him; but were I to do so I fear he would wish me at Jericho. Being old and heavy, I "go in for" ease of transport, and do not care a button about speed, so far as I myself am concerned. In discussing tricycling, as well as other matters, it is sound policy to distinguish carefully between ascertained facts and mere personal opinions. Now, the question of a cross-handle bar or spade handle for steering I regard as belonging chiefly to the latter category. I have a great objection to the cross-handle; it seems to bar the rider into the machine in the first place, and though it may "give great support to

the body when brought forward on the machine," it induces, if it does not even compel, the rider to adopt that attitude which is to me an abomination. That C. Leni has had several machines, having both handles to steer, through his hands that he found difficult to sell, I can surely admit as evidence that double-steering is objectionable—even if the difficulty of selling these machines actually arose from the mere fact of the double-steering, of which he gives no evidence, that would only prove that the mode adopted for accomplishing that object was inefficient or interfered somehow with other functions.

The superiority of large wheels geared even, or small wheels geared up as driving-wheels, surely admits of becoming an ascertained fact by judicious experiment, so that if any superiority on either side actually exists, it cannot be a mere matter of opinion. *Primâ facie* it would seem that from generally-accepted axioms in mechanics, as well as from the behaviour of carriages propelled by horse-power, the larger driving-wheels ought to be preferable; but when I find men who are certainly skilful cyclists, and who know absolutely nothing of mechanics, and, consequently, have no preconceived notions to prejudice their judgment, deliberately assert that they find a practical advantage in the newer machines with the geared-up wheels, both as regards speed and ease of propulsion, I have no reason whatever to doubt the fact. What I want to ascertain is whether the advantage is really gained in consequence of, or in spite of, the smaller geared-up wheels, and if in consequence, I want an explanation of the fact, for I confess myself unable "to figure it out." The question in my mind is whether the declared advantage of having the smaller wheels may not in fact be due to some other cause operating in the newer type of machines. Certainly there may be less resistance to an adverse wind to some extent, and again in ascending an incline, the position of the rider is less displaced than when large wheels are employed; but a strong adverse wind is rather an exceptional than a general condition, and as far as my experience goes, a rough surface has more effect injuriously than displacement of the rider's position, and with a rough surface large wheels I have found preferable to small ones.

Before concluding, I will ask leave to make a comment on Mr. John Bell's remarks in your last issue, who puts it rather mildly when he says, "To me there is no pleasure in dismounting and pushing." Well, perhaps not; but that is scarcely in question. I, like himself, usually frequent hilly neighbourhoods, and though I have power-gearing attached to my machine, which gears down a 50in. wheel to 34 or 25in. at my option, so that I can really ride up almost any incline, I find it is *practically less fatiguing* to push up all hills that I cannot ride up without the aid of the power-gearing. It is true that with a Tandem the pushing is, perhaps, not so handy as with my single machine, which is peculiarly convenient for use in that way, as it runs very easily, does not run back, so that one can stop pushing anywhere on the hill without any inconvenience, and actually assists me in mounting a hill, having something to lean upon and taking my weight off my legs. Without going so far as to say that I "take pleasure" in pushing my machine, I certainly do say that when I want to get up a hill I prefer doing so by pushing the machine to having to get up by riding it, or by simply walking up.

Gamma Sigma.

ORGAN WINDCHESTS.

[26537.]—WOULD Mr. Audsley kindly say whether Roosevelt's patent windchest is suitable for a chamber organ, and if any firm has the right of making it in England? I should also like to ask what size the feeders should be for an organ of ten stops, supposing the bellows to be supplied by three feeders worked with a three-throw crankshaft, and what the diameter of the flywheel ought to be? In a case where this method of blowing was adopted, the work proved to be very laborious—more so than if the usual lever handle had been provided. As this may have arisen from some fault in the construction of the apparatus, perhaps Mr. Audsley can give the name of a firm of organ builders who could satisfactorily make this kind of blowing apparatus. I have found the "Notes on the Chamber Organ" most interesting, and I believe many readers besides myself are looking forward most anxiously to the time when the art of organ building will be treated in a practical manner. All the works relating to the organ which I have been able to obtain invariably omit to give the dimensions of the various parts of the instruments they describe, and this is exactly the information which would be most useful to amateurs.

W. H. H.

[26538.]—I SHOULD certainly advise "C. H. D." to have nothing to do with the windchests he refers to in his letter. What benefit may be derived from them, and the benefit would be extremely small, is outweighed by the extra trouble and increased complexity. In amateur-made work nothing is better than the ordinary soundboard with slides. Have nothing to do with pneumatics of any kind. They are very liable to leak, far more than the ordinary soundboard, and waste a quantity of wind.

Uranium.

DIATOMS—VEGETABLES OR NOT?

[26539.]—IT may interest microscopists to know how I saw one of those boat-shaped diatoms behave under the microscope. It was going ahead at a good pace when it came close to a "rock," and stopped for a bit. It then went ahead again, and got under the "rock," which heaved about it and nearly upset. The diatom next finding, I suppose, it could not get out the other side, backed out and went clean round. Diatoms are, I believe, now generally held to be vegetable organisms. I would like to know the proof thereof. Did that look like a vegetable act?

Londiniensis.

SPRING SAFETY VALVES.

[26540.]—THE following table from actual workshop practice may interest some of your readers; it shows the behaviour of different springs under various loads:—

Turns in Length	11	14	14	14	14	13	13	13	14	14	14	15
	in.	in.	in.	in.	in.	in.	in.	in.	in.	in.	in.	in.

Liverpool. **P. F. Otto.**

NEW OPTICAL GLASS.

[26541.]—IT would appear from your report, on p. 211, of the meeting of Royal Microscopical Society, that at last some real advancement has been made in the art of making glass for optical purposes. Mr. Crisp states that all particulars as to the optical qualities of the glass were published, together with "indications as to the best kinds to be used in the construction of objectives for telescopes, &c." As the ENGLISH MECHANIC circulates largely among opticians, both amateur and professional, in all quarters of the globe, may I earnestly ask some of our friends, who have access to the catalogue to which Mr. Crisp refers, to copy out and send to this journal the particulars of the refractive and dispersive powers of these new glasses?

Some of us will be glad to be able to compare their theoretical properties with those of the glasses in ordinary use.

Orderic Vital.

DOUBLE-ENGINE RUNNING ON THE MIDLAND RAILWAY.

[26542.]—NO doubt the statements contained in the letter by Mr. Charles Rous-Marten, page 263, No. 26507, are based upon evidence or facts which he obtained when in this country; he must, however, either have been fortunate in the time when he made his observations, or circumstances must have very greatly changed.

The enormous amount of *unnecessary* double-engine running on the Midland Railway is a most serious matter for consideration, as it is the great cause why the locomotive working expenses are not further reduced. If the long trains were well filled with passengers, there would be no cause to complain; but this is not the case. Numbers of empty compartments and carriages may daily be seen, and it is this hauling of useless dead weight at express speed which necessitates the double engine running on the Midland Railway. Constant travellers on that line will also confirm the statement that the trains are not as punctual now as they were previously, and the reason is not far to seek; the running speed has been very greatly increased, until, even under favourable circumstances, time can only just be maintained, and unfortunately the number of extra, or conditional stops, has been increased to a serious extent.

If any of your readers will refer to a Midland time table, they will find on almost every page that trains, and some of the best and most important expresses, are to stop at certain stations to pick up or set down, when required. An extra stop means a delay to the train of from three to five minutes, and it follows that, if a train has to make several such stops, as between Bradford and Leeds, Liverpool and Marple, at Chesterfield, Luton, and other stations, it is absolutely impossible for punctuality to be maintained.

Mr. Marten says he has never seen a train from St. Pancras with a pilot engine if under 15 vehicles. I may, however, mention that I have ridden in a train when an engine of the 1667 class has had to take a pilot with only equal to twelve; this, of course, was unusual, and was only done by one of the 1667 class of "failures." It is a fact that these engines, through being badly designed—that is, having boilers both theoretically and practically too small, have lost more time, and necessitated more pilot working in the two years of their existence, than have all the 800 class since they were built in 1870.

If the Midland Company would reduce the number of conditional stops, and take off the empty carriages on the trains, punctuality would be regained, and a much-required improvement, which I have long advocated, could be introduced—namely the addition of third-class dining and sleeping carriages, the former of which would save considerable time at Normanton and other refreshment stations.

Clement E. Stretton, Consulting Engineer.
306, City-road, London, E.C., Nov. 20th.

FOUR-CYLINDER ENGINES.

[26543.]—REFERRING to the article on "Triple-Expansion Marine Engines" in the "E. M." of Nov. 12, it may interest some to know that a four-cylinder engine has already been tried in a screw steamer (of 900 tons burden), built about 1871 by an East Coast firm, and that it gave so little satisfaction that they were, a few years ago, removed and replaced by the ordinary compound engine. However, some improvement in the construction of such an engine may lead to better results in future.

J. T.

USEFUL AND SCIENTIFIC NOTES.

Solanine.—An account of the properties of solanine has recently appeared in the *Bulletin Général de Thérapeutique* from the pen of Dr. A. G. de Montguyon. Solanine poisons the terminal motor plates of organic life, narcotises the medulla, spinal cord, and nerve trunks, and so produces paralysis of the terminal extremities of the sensory and motor nerves. These physiological effects allow solanine to be classed as an analgesic agent. Solanine may be prescribed without risk in strong doses. It has none of the inconveniences of morphine or atropine, has no cumulative action, and is specially a substitute for morphine. It does not cause congestion of the brain, even in elderly people, and probably not in children. In all conditions of excitement, spasm, or pain, solanine may be employed with a prospect of success. The ordinary dose is thirty centigrammes three or four times a day. It may be given fasting or after meals, and the dose may be greatly increased. For hypodermic injections a solution of the chlorhydrate in distilled water may be used in the proportion of from one to five centigrammes per dose, administered from two to four times a day.

Chemical Apparatus and Chemicals.—Messrs. Mawson and Swan, of Newcastle-on-Tyne, have sent us one of their new catalogues of chemical apparatus, chemicals, &c. It is nicely got up, and is freely illustrated, while the explanations of the various apparatus are all that could be desired in a work of the kind.

MR. L. TIETJENS, of Stassfurt, Germany, has recently patented an ingenious method of damming back the flow of water in shafts by the application of the well-known fact that certain salts increase their volume very materially by the absorbing of water of crystallisation in hardening. To accomplish this, he takes either calcined soda, anhydrous alum, kieserite, or oxychloride of magnesium, mixes them into a paste, and then immediately injects them through a suitably arranged pipe into the fissures through which the water flows. It is said that as this paste hardens, it swells enough to fill all the interstices of the rock and to renderit water-tight.

THE Board of Directors of the Berlin Machine Factory, formerly Schwarzkopf, has announced its determination to give up the building of any more locomotives, but instead, to give more attention to the development of torpedo-boat engines and to patented specialities. This may be considered the next most important factory for locomotives after that of Borsig, recently closed, and there can be no doubt that other works will have to adopt the same policy, if in Germany the manufacture of locomotives is ever again to become a remunerative business.

REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[60334.]—**Falling Bodies.**—As "Vulcan" proposes a problem to me, I suppose I must give some answer. I labour, however, under this difficulty, that the data are partly unintelligible, and, besides that, they are put in such away that it is uncertain how much is given by them. In addition to this, the problem consists of two questions; the answer to the former being self-evident, without any calculation, and, moreover, quite independent of the data! If a body be dropped from *a* (for this is what his words really mean), it will pass through the centre of force, *c*, and go to an equal distance on the other side of it and then return, whatever be the function of the distance according to which the force may vary. As to the second question of his problem, he asks me to measure a period of time in units of linear distance. Perhaps I may attempt this if he shows me first how to measure momentum by quarts. This is the gentleman who tells us that he differs from Newton's "Principia" in the solution of the present problem. I now believe that he is only making fun of the readers of the ENGLISH MECHANIC.—DUBLINIENSIS.

[60552.]—**Air-Gun Trigger.**—The trigger plate is fixed to the gun-barrel by a corresponding plate, which is soldered on side of barrel (a brass tube) for this purpose. The air passes into barrel through a hole at side of pin. The valve is conical, with a stem for spring working on, and an outer case, having holes for air passing in, is screwed on seat, keeping valve and spring in position. A piece of W. I. tube made to screw on air-chamber, and having a solid piston, will answer for pump.—P. L. R.

[60596.]—**Pump.**—The querist had better use an air-pump for forcing his vitriol to the height required. This is the plan adopted in many chemical works. Have a cast-iron vessel made of the size required to hold his vitriol, with an egg-shaped bottom. Then place an ordinary wrought-iron tube so that it shall go to the bottom of the vessel; then it is continued through the lid at the top, and thence to the height required. Now connect a tube from his air-pump to the lid of his vessel; fill the vessel, through an opening in the top, about two-thirds full of vitriol, fasten the cover of the opening tight; apply air pressure, and the vitriol will be forced out up the tube. A pressure of about 25lb. per sq. inch will be required. The querist need have no fear of the action of the vitriol on his iron vessels, as the writer has had the same iron vessel in use for seven or eight years, and his air-pump will not come into contact with the vitriol. If further information wanted, ask.—CHEMISTIANA.

[60623.]—**Dynamo.**—TO "S. AND E.," COVENTRY.—The amount of current an armature wire will bear depends, to a certain extent, on the arrangement of armature. Our own practice is not to exceed 3,500 ampères per square inch. You will need considerable practical experience as well as theoretical knowledge, before you will be able to design a dynamo to give a stated current and E.M.F. at a given speed. We should advise you to read the paper read to the Society of Telegraph Engineers and Electricians, by Mr. Gisbert Kapp, on "The Pre-determination of the Characteristics of Dynamos."—S. AND E., Coventry.

[60659.]—**Getting up Fire Brasses.**—The atmosphere of the place must be very bad if the work discolours before it can be burnished and lacquered; but here is a difficulty—"burnishing" is the highest form of polish, and you ask what lubricant to use to "prevent scratching." Nothing. If scratches appear, there must be something wrong with the burnisher or the workman. The brushes are wire, as a rule, the finishing being done with bobs made up of discs of cloth held firmly together between two plates. Rottenstone with oil or spirits will do the rest.—E. G. M.

[60664.]—**Pendulum.**—This question is well answered on p. 80, and in previous volumes.—NUN. DOR.

[60665.]—**Scent.**—Certainly a scent can be made from verbena or lemon-grass. The oil is extracted from the fresh flowering V. odorata, or Aloysia citriodora, in the usual way by distillation, and is mixed with rectified spirits of wine. A little oil of bergamot and oil of lavender or essence of ambergris are often added. But oil of verbena is generally imported from India, where it is obtained from Andropogon citratum. If the question should be asked whether it is worth while to attempt to make the scent here from native-grown plants, I should say decidedly no, because the perfumes of tropical plants are never fully developed in this country, even when grown in hot-houses, I believe; and besides it would not pay commercially.—SAML. RAY.

[60668.]—**Etching Brass.**—See indices. Nitric acid, sulphuric acid, and hydrochloric acid may all be used; but the main part of the etching will be done with nitric. See p. 559, last volume, for instance.—NUN. DOR.

[60671.]—**Boiler Incrustation.**—The reason the boiler became tight when the use of the soda was discontinued seems obvious enough: the leaks became stopped by incrustation.—NUN. DOR.

[60676.]—**Mother o' Pearl.**—This can be cut by means of discs of iron and emery, or in the same way as a lapidary cuts and polishes stones, &c.; but the amount of "polishing" on mother o' pearl is very small. Use the very finest putty powder and a soft bush. Great care is required in cutting it. There is something on the subject in Campin's "Turning in Wood, &c.," and no doubt also in Holtzapffel.—NUN. DOR.

[60677.]—**Vergara's Slides and Woodbury Tissue.**—Where these not described in No. 1,114, p. 475? Surely anything further could be obtained on application to the makers.—I. J. H.

[60681.]—**Water Clock.**—The conical drum is for regulating.—J. B.

[60685.]—**Electrical.**—The kind of carbons are fully described at p. 71. They are moulded carbons, of course; but you can cut them out of retort scurf if you like—and can.—C. B.

[60686.]—**Staining Iron Black.**—If it must be a stain, would the oil or Lancashire black seen on some tools, bits, &c., do? Any way, you will find suitable processes in back volumes.—J. B.

[60690.]—**Wood-Carving.**—All carving that is worth doing depends for its forms on the cunning hand and eye of the workman, not upon the shape of the tool. I mean, you can no more produce fine carving by trusting to the curve of your tools than good drawings by the use of French curves. Even if it be but a row of flutings to relieve a hollow moulding, it is just the slight irregularity of hand work which makes the difference between a pleasing and a lifeless piece of work. It is true you want some special tools: you cannot cut those flutes without a bent gouge of suitable size and curvature. But this tool must be servant, not master; and, as I happened to notice in the practice of a first-rate professional, you require the constant aid of a pencil even for fluting. You run your moulding and then mark, and then pencil your flute edges. For less simple cases you have, after roughing out, to pencil in detail, and a carver should be no more a slave to the drawing than to the tools. In short, carving requires taste and feeling. I like "G. H. H.'s" statement of his wants. Surely every worker in wood should be taught some skill of this sort. There are many cases in which carving is the quickest way of making a tidy finish. Speaking as an amateur, I find it quicker to do a simple leafy edging to a curved piece of wood such as a bracket than to finish it up square with spokeshaves and rasps. Unhappily, it is not so much the first step that is grievous, but later on, the difficulty of obtaining reasonably good designs and finding examples of really fine style to improve one's standard becomes great. The average trade designs are lifeless, and the execution, with all its dexterity, is lifeless too. The same sort of "handling" obtains in carved wood and in embossed brass as in stamped and machined counterfeits or stamped paperhangings. The only fine carving of which there is much to be found is Gothic, and it is not easy to use it in ordinary work. I have never found even fairly good designs in handbooks of wood-carving, and the Royal School at South Kensington feel the difficulty acutely.—W. A. S. B.

[60696.]—**Dynamo.**—Is not the dynamo mentioned a Gramme? and has not that been described almost *ad nauseam* in recent volumes?—C. T. M.

[60701.]—**Japanning.**—A turning barrel is the best thing for taking off sharp edges; but for japanning heat is requisite.—J. B.

[60700.]—**To Draughtsmen, &c.**—The way in which I managed with trig. was this. The chord of any arc of not more than 180° is double the sine of half the angle. So I divided 360° by the number of divisions into which the circle had to be divided multiplied by 2. Then from table of natural sines found sine of this angle, which multiplied by the diameter gives the chord. Now, "Nephesh," you must be a peerless expert at judging distances if you can set dividers within $\frac{1}{20}$in. of $\frac{1}{13}$ of any line, first go. And although you may be this, if pitted against a "scheme-a-jack," armed with a sector, "E. L. G." tells us of, I rather think you would find yourself doing the "fiddling." And if this be so, what about the workman incapable of the mental arithmetic and eye-measuring (and there are many such) that figure so largely in your methods. Many thanks, "E. L. G." Your replies have been of great service to me, as I find from them I have invented what was already well known (a disappointment I have experienced more than once), my instrument being simply a sector with semicircular strut and set-screw.—WORKMAN.

[60702.]—**Liquid Gold.**—The querist seems to know what Duterte's process is; but he might, for experiment, dissolve a grain of fine gold in aqua-regia, and concentrate until deep blood colour; then add half a litre of hot distilled water containing four grammes of cyanide of potassium. Stir, and filter.—E. G. M.

[60744.]—**Question in Dynamics.**—How the monkey can raise the weight without raising himself also (as stated by "M.I.C.E.) is a mystery. He does not move, so can do no work, and yet raises the work against gravity. If either the monkey or weight begins to move up, while the other is stationary, it will put more tension on that side of rope (in consequence of motion against gravity). This tension immediately moves the body on the other end of the rope, and continues to do so until it is equalised by the motion of that body. There being no friction, the tension will be instantly compensated, and both the monkey and weight will rise with equal velocities. "W. A. S." must admit that to put extra tension on the rope the monkey must raise himself if only a small fraction of an inch. If not, he agrees with "M.I.C.E.' in saying that the monkey can do work without raising himself, which is against all laws of mechanics.—R. W. W., Newcastle-on-Tyne.

[60744.]—**Question in Dynamics.**—This amusing puzzle has been solved at last by "Nephesh," so "W. A. S." must acknowledge himself to be in the wrong, and my original solution turns out to be right after all. I have rather put myself out of court by endorsing the argument of "W. A. S."; but *magnum est veritas*, &c. To take a homely illustration. From my window I see two invalids being pushed along in Bath chairs. Now, suppose the two chairs with their occupants to be placed some distance apart, and a rope passed from one to the other; if one of the occupants pulls the rope both chairs would be put in motion, and would approach each other. Now, suppose the road to consist of two steep hills, meeting at an apex like the letter A, with a wheel or pulley at the apex, over which the rope passes, a chair being on each slope; as before, when the rope is pulled both chairs will ascend the two slopes. Now suppose the two slopes to become so steep as to be vertical; when the rope is pulled, precisely the same action takes place as before, and the two chairs would approach each other at the apex. When the chairs were on the level, if there were no friction, they would go on approaching each other when once set in motion; but when on the two slopes, the action of gravity would also prevent any motion except that due to the pulling of the rope, and the same when the rope is vertical. There is no tendency to accelerated motion as "W. A. S." supposed. If the pulley worked without friction, both chairs would travel upwards at the same pace.—M.I.C.E., Bath.

[60774.]—**Heating Conservatory.**—Would the writer state the diameter outside, and hole inside, with the length he recommends of tube?—JAMES J. GRUNDY.

[60781.]—**Corundum for Aluminium.**—There is a mistake in last week's "E. M." The correct analysis of Kaolin is—

Alumina (Al_2O_3)	40·76
Silica	46·52
Lime..............................	3·17
Water	9·55
	100·00

—F. W. GERHARD, Wolverhampton.

[60796.]—**Arithmetical Question.**—In order to find the amount of ten equal annual payments to satisfy principal and interest of £1,000 mortgage, "Puzzled" should in the first place calculate the amount (*a*) to which £1,000 would increase at compound interest in ten years; secondly, the amount (*b*) to which an annuity of £1 would increase at like compound interest in the same time. Then *a* divided by *b* will give the annual payment required.—S. M. COX.

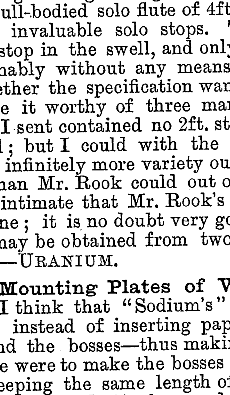
[60815.]—**The Sun's Radiation.**—A. Treyer Evans attempts to give an explanation of the construction of air and vacuo thermometers; but he does not appear to know that an *absolute* vacuum is an *absolute* impossibility. The exhausted (?) glass tube, then, does absolutely contain a modicum of air, however ridiculous "A. T. E." may consider it. I wish to be informed the value of the knowledge that the vacuo thermometer registers on three days, say, 80°, 90°, 100°. Although the air thermometer on each occasion may record 60°, does it indicate more or less moisture in the air, a lengthened exposure to sunshine, or what? I do not think fruit-growers will be much edified by the explanation of "A. T. E."—B. R.

[60820.]—**Chamber Organ.**—I am extremely obliged to E. Franklin Rook that he considers the specification I sent in reply to the above query

"good." I am sorry to say I cannot return the compliment with regard to the specification he sends of his own instrument. I am perfectly aware that to dispose the stops on to three manuals is, for a large organ, most judicious and extremely useful; but in the case of a small organ, matters differ somewhat. Cost must be taken into consideration. The third row of keys, for the keys and frame alone, would cost about £3 10s. This is the price of a small wood stop. Better have the pipes as the keys. Then there is the separate action—more cost still. If Mr. Rook will kindly look at the specification I sent on page 245 he will see at the foot of the list great and choir ventil. This to a certain extent provides the third manual. The great and choir occupy the lower row of keys, the swell the upper. To use these for accompanying and solo purposes, the mode would be as follows:—If a solo was desired on the great op. diap., the choir ventil would be off, and the accompaniment could be with the swell. If a solo was desired on the choir vox angelica, the choir ventil would be on and the great off, when the accompaniment would be the swell vox celeste. Then to use the swell stops individually as solo stops, requires in a room a very soft accompaniment. This would be provided by the vox angelica, with the choir box closed. Now, I don't deny that this can be done on the three manual, but if it can be accomplished on the two manual, why go to the extra expense of the third row of keys? By having only two rows of keys, the whole of the organ stops can be brought into use for a grand forte, whereas, in Mr. Rook's organ this cannot be, as there is no provision for coupling the choir to the great. I do not think this choir to great coupler really needful in a large church organ; but it is essential in a small organ to obtain all the power you can. In Mr. Rook's specification there are, in my humble opinion, three almost useless stops—viz., principal, gemshorn, and piccolo, except simply for augmenting the general organ tone. There is no full-bodied solo flute of 4ft. pitch, one of the most invaluable solo stops. There is no string-toned stop in the swell, and only one in the choir, presumably without any means of expression. Altogether the specification wants remodelling to make it worthy of three manuals. The specification I sent contained no 2ft. stops, nor are they needful; but I could with the two octave couplers get infinitely more variety out of it, and power, too, than Mr. Rook could out of his. I do not mean to intimate that Mr. Rook's organ is an indifferent one; it is no doubt very good, but the same effect may be obtained from two rows at a less expense.—URANIUM.

[60839.]—**Mounting Plates of Wimshurst Machine.**—I think that "Sodium's" plates will not crack if, instead of inserting paper between the plates and the bosses—thus making them bed unevenly—he were to make the bosses not quite so long, but keeping the same length of projecting pieces, so that he could slip boxwood washers on to the projecting pieces without interfering with the requisite length—that is to say, the solid bosses and washers to make up together the required length—and then he could insert the paper between the washers and solid bosses without making the bedding of the plates uneven. I should be obliged if "Sodium" would inform me whether he has tried having a turned spindle with centre holes, which would enable him to true up the bosses on it between the centres, with some small contrivance to key them to it to cause them to revolve with it, and, if so, with what results?—G. M. S.

[60856.]—**Battery.**—To Mr. Bottone.—Get piece of electric light carbon about $\frac{1}{2}$in. in



diameter and $3\frac{1}{2}$in. long; procure a wide-mouthed glass bottle about $3\frac{1}{2}$in. in height and $1\frac{1}{2}$in. wide. Cast a leaden lug around the top of this carbon, taking care, however, to have the carbon not central; the lug must be of such a size to fit nicely the neck of the bottle. At one side of the lug must be drilled a hole, about $\frac{1}{4}$in. diameter, to allow of the insertion of a zinc rod; a binding-screw may be screwed into the leaden lug to make easy connection with the coil. The zinc rod must also be furnished with a binding-screw for the same purpose. When the lead lug has been thus shaped and drilled, it should be warmed and well basted on the underside with hot melted pitch, a little of which should be also painted round the upper part of the carbon rod (i.e., the part nearest the lug). In order that the zinc rod should not make contact with the leaden lug, a small piece of indiarubber tubing should be drawn tightly over it, at the place where it rests against the lug. This battery should be charged with a chromic acid solution, made as follows: Chromic acid, $\frac{1}{2}$lb.; water, 1 pint; sulphuric acid, 3oz. Mix, and allow to cool before using; the battery should not be more than half filled with the fluid. The annexed sketch gives an idea of the make of the cell: A, the glass bottle; B, the carbon rod; C, the zinc; D, the leaden lug; E E, binding-screws.—S. BOTTONE.

[60864.]—**Gas Products.**—Replying to Robert Perry, no doubt the stoppage in ascension pipes arises from the formation of pitch caused by the high heats near the retort mouthpieces. There are several remedies other than structural alterations. A very simple one is to put about half a pail of water over the last three shovelfuls of coal when charging. An impending stoppage can always be detected by the bottom of the pipe being quite dry. If water is allowed to trickle down the outside of the pipes most liable to stop up, care being taken not to allow more water than the heat of the pipe will evaporate, it will be found to answer very well. The best means for accomplishing this, of course, depends upon local circumstances. It is useful too, to let the hydraulic run out every day, and keep the dip as shallow as possible, consistent with leaving enough in to form proper seal.—F. M. E.

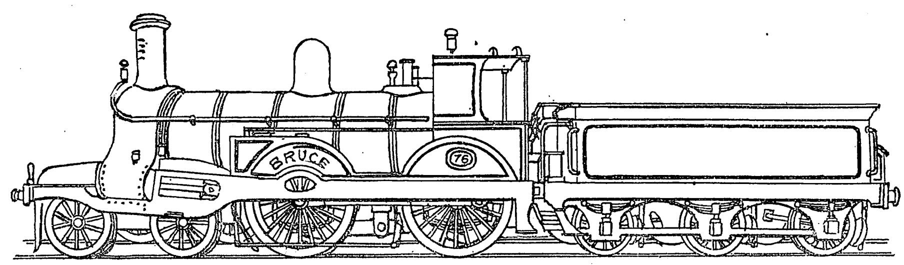
[60870.]—**Horsehair.**—A hair rope is easily made, if querist can obtain one of the twisters used by farmers for making hay ropes, and get someone to turn it for him. Fasten a bit of the hair on the end and feed the hair to it as the machine is revolved. The rope of hair must be twisted hard and allowed to curl up, and lie by for a while to set. If he does not know what a twister is like, I will send a sketch of one he can make for twopence.—DOCTOR MEDICINÆ.

[60877.]—**Finishing Cast Steel in the Lathe.**—We have large quantities of cast steel, and use neither water nor any other lubricant.—J. H.

[60877.]—**Finishing Cast Steel in the Lathe.**—Cast steel must be finished dry in the lathe with a slow speed, and afterwards filed up and finished with emery cloth.—WALTER MATHER.

[60877.]—**Finishing Cast Steel in Lathe.**—I should advise you to ascertain by experiment what you wish to know, as it would not take long, for no one can tell you, as the quality of steel varies greatly. What the turners told you is quite right, as they might have worked steel of different qualities—viz., one oil, one suds, and the other dry; but I always find it best to work it dry myself, as I have worked it this last 10 years. You should rough it to near the size, then with a very sharp tool and speed to suit, take a cut over, leaving $\frac{3}{1000}$in. above size; then, if tool is dull, rub with oilstone, take another cut, leaving barely $\frac{1}{1000}$in.; then with a very fine-cut file (known as dead smooth), finish to required size. But if it is for common work, any of the three ways will do. The way I speak of is for tool work, which requires the greatest accuracy.—LUMSIE.

[60900.]—**Highland Ry. Loco.**—In reply to "Amateur" I send herewith sketch of Bruce, the Highland Railway Locomotive at Edinburgh, which is one of six made for the company by the Clyde Locomotive Company. The following are some of the dimensions:—Boiler: length 9ft. $9\frac{1}{2}$in.; outside diameter 4ft. 2in.; tubes, 223, $1\frac{3}{4}$in. diameter by 10ft. 4in. long; fire-box, length inside at top, 5ft. 4in.; length inside at bottom, 5ft. 6in.; breadth, 3ft. 5in.; height, 4ft. $9\frac{1}{2}$in.; cylinders, 18in. by 24in.; diamer of bogie wheels 3ft. $9\frac{1}{2}$in.; diameter of driving and trailing, 6ft. $3\frac{1}{2}$in.; wheel base, bogie wheels centre to centre, 6ft. 0in.; driving to trailing, 8ft. 9in.; centre of bogie to centre of driving, 9ft. 9in. Boiler painted light green; frame maroon. Six-wheeled tender; 2,250 gallons water. Fitted with automatic vacuum brake.—B.



[60892.]—**Annuity and Estate.**—I notice in the printing of my answer to above, p. 268, there is a compositor's error. In giving the value of $1{\cdot}05^{-32}$, it is stated to be equal to $\frac{1}{1{\cdot}05^{-32}}$; it should, of course, be $\frac{1}{1{\cdot}05^{32}}$.—SURVIVOR.

[60899.]—**To Chemists.**—(1) Nitric acid acts on iron according to three equations, varying as its dilution:—Very dilute, $Fe + 2HNO_3 = Fe2NO_3 = H_2$. Dilute, $Fe_4 + 10HNO_3 = 4Fe2NO_3 + NH_4NO_3 + 3H_2O$. Strong, $Fe + 5HNO_3 = Fe3NO_3 + 2NO + 2H_2O + H$. Nitric acid of sp. gr. 1·38 at temp. 31°, or sp. gr. 1·42 and temp. 55°, has no action on iron—it renders it passive. (2) Ferrous sulphate and bichromate of potash. $6FeSO_4 + K_2Cr_2O_7 + 7H_2SO_4 = 3Fe3SO_4 + K_2SO_4 + Cr_23SO_4 + 7H_2O$.—E. F. S.

[60906.]—**Lens.**—To T. PERKINS.—I am in want of a lens to do such work as described by you last week. But I wish also to take long-distance views with it. Will you say if this lens is suitable? What is the largest size plate it will cover perfectly? Does the front combination screw off? If so, then, how is stop used, and what is the advantage or disadvantage of working with back lens alone? What is its diameter outside over all?—T. BROWN.

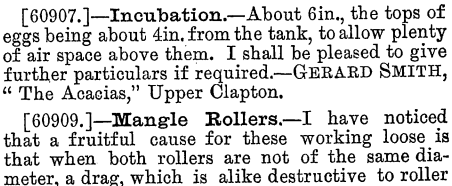
[60907.]—**Incubation.**—About 6in., the tops of eggs being about 4in. from the tank, to allow plenty of air space above them. I shall be pleased to give further particulars if required.—GERARD SMITH, "The Acacias," Upper Clapton.

[60909.]—**Mangle Rollers.**—I have noticed that a fruitful cause for these working loose is that when both rollers are not of the same diameter, a drag, which is alike destructive to roller and rags, is the result.—A., Liverpool.

[60909.]—**Mangle Rollers.**—If you will make about eight wedges of wood about 12in. long, of oak or ash, and of a sufficient thickness to fill up the gap round the shafts, and insert them, four at each end of roller close to the shaft, and drive them up tight, and then put four iron wedges in each end of the roller. You will not be troubled with them again coming loose if done properly. I have done scores of rollers in this way.—WALTER MATHER.

[60918.]—**Screw-Cutting.**—All you need to do when cutting odd pitches of screws is to put a piece of wood or iron between the back centre and the carriage of the lathe, and let the carriage be against this before commencing to cut the screw, and at each cut run the carriage against the wood or iron, and wait till the nut will gear, and then you will be all right.—WALTER MATHER.

[60918.]—**Screw-Cutting.**—Put down the pitch in fractional form, and the numerator indicates the least number of inches which the saddle must travel to fall into gear again—5, 7, 9 $= \frac{1}{5}\frac{1}{7}\frac{1}{9}$; in each case 1in. is the least number of inches or any multiple of 1 according to the length



of screw being cut, as 2, 3, 4, &c. Mark the lathe-bed with chalk, or measure from headstock, unclasp the nut, and move the saddle to either one of these distances. The diagram illustrates this in a graphic way.—J. H.

[60918.]—**Screw-cutting.**—In cutting either odd or even pitches in screw-cutting lathe it is best to work as follows. Your article must be held firm between the centres, your wheels arranged to cut the thread wanted; your saddle must be brought to a stop against the loose headstock, or a block of wood or iron placed purposely to stop in the right position; set tool in holder firm and in place to begin, turn over the rest handle to take up the backlash of the rest-screw (to the right for right-hand screws, to the left for cutting left-hand screws). Now pull round your live centre until your nut falls into gear with leading screw. Before starting your lathe mark with chalk the face-plate and the wheel which is on the leading screw, preferring the top or highest part of both, and each time take a cut; see that your saddle and the chalk marks are in their right places (before starting). If they do not come right (in odd pitches they seldom fall on), pull your live centre round, or run the lathe (with the nut out of gear) until the chalk marks are at the top (the place of starting); the saddle you must pull back against the block. Some men use a chalk mark for saddle; I prefer a block. I have seen men place their saddle anywhere, start the lathe, and try to put tool in place; but good work is never done in such haphazard ways. I do not know if your lathe is new, or in good condition. All lathes, when worn or used for a time, have backlash, which must be taken notice of to turn out good work. Further advice if desired.—WESTWOOD.

[60921.]—**Petroleum Spray.**—I have seen diagrams of a petroleum furnace where the petroleum was blown down a long slanting passage by the steam-blast through a series of two or three iron grids, the steam entering at the end and meeting the petroleum dripping down from above, the supply of both being regulated by a valve and turncock respectively. The blast was blown down on to the surface of hot cinders and fireclay lumps in the firebox. I believe hot cinders and steam, both from another source, unless there was enough steam pressure left in the boiler, if there was one, had to be supplied to start the furnace in the first instance.—E. CONRY.

[60922.]—**Albatross Skin.**—Will not the albatross skin make a good tippet for a lady's shoulders? Some wiseacre may tell "Rara Avis" what to do with the skin; but for the feathers, heed me. I have seen a naturalist treat a large bird, which he had just stuffed, by daubing it all over with a plentiful supply of starch; the commonest starch will do. Blend a good supply of it with cold water into a thinnish paste, and lay it thickly over the feathers. Let it dry for a couple of days, thoroughly dry, then, beginning at the head, knock off the starch (no use objecting to the dust from it) from every feather down to the very tips, and you will find that blood stains and other dirty spots have disappeared, and that the feathers have been plumed quite beautifully. "What man has done, another may do."—H.O'B.

[60924.]—**Portable Electric Light.**—As far as the E.M.F. is concerned your lamp will require about four of such cells as you mention. But they are not of much use for the purpose, as oxychloride forms on the zinc plate, thus increasing the resistance of the cell very rapidly, and reducing the current. You can remove the said deposit by washing it in dilute hydrochloric acid.—W. HOLDER, Newport, Mon.

[60924.]—**Portable Electric Light.**—The E.M.F. of the chloride of silver battery is about 1·19 volt, no matter what the size. If charged with caustic potash, the E.M.F. rises to 1·5. Supposing the latter modification is used, and that the 2c.p. lamp has a resistance of 3 ohms, then you would need at least three cells to do the work, and give you a little margin for internal resistance of battery itself. This battery will run about an hour, after which the potash solution must be renewed. The chloride of silver must also be replaced after the battery has been used two or three times.—S. BOTTONE.

[60924.]—**Portable Electric Light.**—Our "Standard" chloride of silver battery of three cells, as used for surgical purposes, will serve for 50 operations of about 30 seconds each duration, and will then remain strong enough for medical inductions. If six cells of the same type are used, by adding a little alkaline solution to the existing liquid the battery can be made powerful enough, if moderately used, to light a Fairy lamp of two candles for nearly one minute for about fifty times from one charge; but it is not advisable with this strong solution to let the battery remain idle for more than thirty days when same is required and used for intermittent lighting purposes.—SHIPPEY BROTHERS.

[60924.]—**Portable Electric Light.**—Certainly two, and probably three, if the cell be what is known as "Clark's Chloride of Silver," as this has an E.M.F. of only 1·03 volt. If Skrivanoff's, which is also a chloride of silver cell, but moistened with caustic potash solution instead of salammoniac ditto, probably two cells would be enough, as the E.M.F. is 1·45. The latter is the best for lighting, owing to the smaller number of cells, and consequently space required. The length of time either would last would depend on the amount of chloride of silver put in. With cells of your size a layer of this, about $\frac{1}{16}$in. thick, would last about an hour of continuous lighting. At the Paris Opera house they use a thinner layer than this, and recharge every evening, which they find more satisfactory than making one cell large enough to last two or three times, especially as the cells are subject to a good deal of shaking from their position in the headdresses, &c. The chloride of silver, however, is an expensive cell to use for the electric light.—E. CONRY.

[60927.]—**Recutting Chasers.**—Put a suitable hob in lathe and apply the softened chaser to it either by a handle on a T-rest or, if a self-acting lathe, fixed in rest and suitable wheels on. You can do inside tool best on tool rest by either cranking it or having a suitable handle, and must be applied at an angle of double the pitch so as to make it left-handed.—T. C., Bristol.

[60927.]—**Recutting Chasers.**—For recutting outside chasers you will have to get hobs the same pitch as your chasers want to be; then put the hob between the centres and tighten the steel in the tool-rest, then proceed as if screw-cutting. Drive a very slow speed with back gear. If you have not got hobs, it would be cheaper for you to buy them. Then, in the case of inside chasers, centre each end of steel, then proceed as if you were screw-cutting.—WALLACE NEWLAND.

[60928.]—**Reversing Gear to Motor.**—This is perfectly feasible. It is only necessary to reverse the direction of the current in the armature, *without* altering it in the F.M.'s. This can be done by rotating the brushes through an angle of 180°. A neat way of doing this, due to Mr. Reckenzaun, is illustrated in the ENGLISH MECHANIC Vol. XLI. page 570, No. 1066, August 28, 1885.—S. BOTTONE.

[60928.]—**Reversing Gear for Motor.**—It would make no difference at all which way you connect your battery to the motor with the object of reversing its direction of rotation. If the current is reversed in the armature alone it would have the desired effect; or, again, if the current was reversed in the field magnets alone (which means a reversal of its magnetism) it would act as required. If both are reversed, which happens when battery-current is changed, then, of course, the motor still continues rotating in the same direction as the relation between armature and field magnets remain unaltered. Now, as neither the above methods of obtaining the desired result is practicable in your motor, the brushes must be reversed, or you must have another pair of brushes attached to a sort of lever arrangement which will throw the one pair out and put the other pair in. I am presuming that you understand about the "lead" given to the brushes. See a sketch in No. 1066, p. 570.—W. HOLDER, Newport, Mon.

[60929.]—**Nickel Plating.**—Dissolve nickel sulphate in liquid ammonia. The sulphate can be obtained by dissolving the metal nickel (either in the pure or commercial state) in sulphuric acid; but the process is not worth the trouble, as the salt is a commercial article and can be bought very cheap. The deposition of aluminium up to the present has not been a success commercially. Scientific authorities have an idea that it will be more readily deposited as an alloy.—W. HOLDER, Newport, Mon.

[60929.]—**Nickel Plating.**—Nickel can be dissolved for electro-deposition by what is known as the "battery process," the resulting solution being the double sulphate of nickel and ammonia commonly used. Attach a plate of pure nickel to the positive pole (carbon) of a powerful battery, such as the Bunsen, and suspend the plate in a dilute solution of sulphuric or hydrochloric acid, in the proportion of 1 of acid to 10 of water. Place a few pieces of clean sheet copper in a porous pot, pour sufficient dilute acid into it to the level of the acid solution in the large vessel, and set the porous cell in it. Attach a sheet of copper to the negative pole (zinc) of the battery, and place it in the porous cell in contact with the pieces of copper already in it. In a few hours the acid will have combined with its equivalent of nickel. Weighing the nickel before and after immersion gives the amount of nickel the solution contains. After removing the porous cell, add liquid ammonia to the solution in the large vessel till it has no effect on the blue litmus paper. To each ounce of sulphate of nickel in the solution 1oz. of chloride of ammonium is to be added. It may be mentioned, however, that the trouble of this operation is saved by purchasing the double sulphate of nickel and ammonia in crystals, and dissolving in hot water. Sorry I cannot answer the query as regards aluminium.—BOBADIL.

[60930.]—**Triangular Tool.**—You cannot have a better or more useful one than is to be made by grinding and set-stoning the end of any suitable for the job old sawfile, leaving it at its normal temper. Also for a parting tool, grind a thin, old, smooth flat file until, say, an inch of the end is free of teeth marks; grind the cutting end a little slanting, according to the nature of the material to be parted.—A., Liverpool.

[60930.]—**Lathe Tool.**—A parting tool for metal is square on the front and from $\frac{1}{16}$in. to $\frac{3}{16}$in. wide, but rather less at back to allow clearance, and flat on top with, say, 5° clearance in front. Triangular tool for C.I. for small lathe of, say, $\frac{5}{8}$in. square steel drawn down to $\frac{3}{16}$in. to $\frac{1}{4}$in. wide in front, and either round or pointed. If for W. I. front angle about 60° to allow shaving to curl. Any book on tools will give illustrations of all.—T. C., Bristol.

[60932.]—**Inlaid Veneers.**—These are built up soldid, carefully fitted, glued, and then taken to a veneer saw-mill and cut into veneers. This is the reason why "O. J. L." found the errors, such as badly shaped curves repeated in each.—B.SC., Plymouth.

[60933.]—**Gut Driving Bands.**—Get a piece of $\frac{5}{16}$in. square steel. Chuck it in lathe. Run in a drill (of size to suit $\frac{1}{4}$in. tap) about $1\frac{1}{4}$in. deep. Bring loose poppet-centre to bear in the hole bored. Mark off 1in. length; turn down ends of the inch length, and cut off. Drill two $\frac{1}{4}$in. holes close together in the middle of the piece; ease off their outer edges with a small rounded cold chisel. Tap the long hole right through, Screw a short length of $\frac{1}{4}$in. steel rod, and cut off two screws to fit. Use a $\frac{1}{4}$in. band of leather, cord, or gut; something without a twist is best. If cord, a coat of shellac varnish improves it. This fastening is chiefly intended for rough, heavy work, and for those out of reach of gut.—HENDON.

[60934.]—**Magneto Machine.**—TO MR. BOTTONE OR MR. EAVES.—Most likely the little spring which should press upon the square shoulder of the spindle is at fault. To get a shock, the spring must just touch the rounded portions (during rotation), and be just clear of the squared portions.—S. BOTTONE.

[60936.]—**Oxygen.**—A bright-red heat is sufficient. The manganese should be put into an iron bottle or piece of gas-pipe. It requires no purification, the gas being sufficiently pure for all optical purposes. About 8 tons per annum was thus treated at the old Polytechnic Institution, and was there passed through a simple washing tank to cool it and condense any moisture that might come over with the gas. From manganese the gas comes off rather slowly, and not at all like the chlorate of potash process, which is more rapid—rather the purest, but more expensive.—E. T. P.

[60937.]—**Photographic.**—Does the querist mean to "copy lantern slides," or to produce them from his negatives? Seeing no meaning otherwise than the latter, I, therefore, give a short account of my experience, and at the same time recommend the following formula by Woodbury: Glycerine, 10 drops; potassium bichromate, 30 grains; glucose, $0\frac{3}{4}$ drachm; gum arabic, 1 drachm; water, 2oz. After solution, filter through a piece of sponge or cotton wool plugged into a funnel. A clean glass plate is flooded with the solution, dried rapidly on a hot-water plate, or what I used was a flat powder-tin filled with hot water; expose from two to four minutes to bright sunshine under the negative to be copied, take it out of printing frame in dark room, and leave it until the evening, when it may be developed by ordinary candle-light. During this interval it absorbs enough moisture to effect development, assuming that it has not been over-exposed. A faint image will be apparent, which is due to the altered bichromate, and the darker the shades of this picture the less moisture it aborbs on exposure to air, and consequently the less tacky. It is, in this state, dusted over with fine-powdered electrotyper's graphite by means of a camel's-hair brush, and, with careful manipulation, the picture may be built up according to the operator's own artistic skill, omitting those portions that are objectionable to the pictorial effect, whilst a wide field for retouching is here opened, by which accessory, and even *forte* points may be introduced, as sheep on a blank lawn, a boat on a pond, that originally stared at the admirer with a disinterested blankness, and so forth. When development has been effected, and all extraneous plumbago removed, coat the plate with a film of structureless transparent collodion, and, after having thoroughly set, wash in several changes of water, so as to remove the unaltered bichromate, drain, let dry, and then mount in the ordinary way. I may add that the solution for coating plates is of very little use after 24 hours, hence it should be prepared immediately before use. Coating the plates must, of course, be conducted in a darkened room, illuminated by a candle. Upon any account, be on your guard against dust, as the tacky film has a great affinity for any little particle it can lay hold upon.—A. TREYER EVANS, Newport, Mon.

[60938.] — **Photography.** — Probably "B." means to ask the difference between burnishers and rolling presses. The latter are the best for general work, but burnishers are much cheaper. In the latter case (burnishers) the mounted photos are forced over a bar of highly polished heated steel, and in the other (rolling presses) the photos mounted or unmounted are laid on a hot steel table and rolled backwards and forwards till they acquire a high gloss, if such is required, or rolled cold, if the subject is a landscape or unmounted.—B.Sc., Plymouth.

[60939.] — **Casting of Gun Metal on Wrought-Iron Shafts.**—A similar query to this was asked some time since, and I then expressed my opinion that it was not practicable. If sound castings are required, the simpler plan would be to cast them as bushes, bore them, and drive them on; but, as this is obviously impossible where a square shaft is concerned, and as it would be difficult to cast a 1¼in. hole 23in. long, straight and true enough for a driving fit, I subjoin some hints derived from the practice of casting iron barrels on square shafts: First, see that the shafts are perfectly free from spots of rust and scale; next make them hot, as you say, so hot that they cannot be handled, but nothing approaching to red heat. If practicable, cast them on end and run at the bottom, the metal rising up the bar; well vent the mould and run the metal dead, so that it shall set as quickly as possible. I should be glad to know the result of your experiment, since this kind of work is always, more or less, troublesome.—J. H.

[60940.]—**Oxalic Acid.**—Before J. Montague Jacques sets up any plant for manufacture of oxalic acid from sugar, he should ascertain the relative cost of the sawdust process. I am under the impression that the oxalic acid of commerce is nearly, if not all, made from sawdust by Dale's patent, 1856. According to Lunge ("Sulphuric Acid and Alkali," Vol. I. p. 319), an attempt was made in France to make oxalic acid from molasses and nitric acid, utilising the nitrous fumes evolved in an acid chamber; "but the yield of oxalic acid was not large enough to compete with the manufacture from sawdust."—C. J. Woodward, Birmingham and Midland Institute, Birmingham.

[60941.]—**Fire.**—As a rule, Scotch people keep their fires in all night and all ordinary house coals serve for the purpose. At, say, 10 p.m., the fire is "gathered," a lump of coal about 8in. square is put on against the grain, and the ashes accumulated during the day are heaped on all round, so as to "damp" the fire. Next morning, on getting up, the gathering coal is struck with the poker or a hammer, and the red fire bursts into a flame.—B.Sc., Plymouth.

[60941.]—**Fire.**—If a piece of sheet-iron just large enough to fit in the bottom of the grate, and having a flange of about 1in., turned up at the front, be inserted every night, and the fire made up with coal and well banked with slack, "E. P." will find the fire will last for quite fifteen hours. In the morning, a few jerks to the iron to liberate the ashes will cause the fire to burn up brightly.—S. Henry Smith.

[60941.]—**Fire.**—In a great many parts of South Wales, especially Pembrokeshire, the fire is very seldom left to go out in the night time. The way in which it is managed is this: a kind of shaly anthracite coal, which is locally called "culm," after having been crushed, is mixed with water and slime or clay in a proportion so as to make the mixture hold together. It is not very important as to the exact proportion in which they are mixed; but it is something like this: a cartload drawn by one horse of clay to about a ton of culm. Before going to bed the fire is covered over with it to about an inch thick, and a hole made in the middle with the poker. In the morning it is only necessary to break this up, and a nice little fire is ready to make breakfast; but if the kettle is left all night on the hob, a minute or two is sufficient to make it boil, if not already boiling. Instead of culm, an inferior quality of coal would do, but not so well as the culm.—J. T. Le Davies.

[60941.]—**Fire.**—Much depends upon the sort of fireplace and the weather: a fire packed to keep in all night, in breezy weather will kindle up too soon; whereas, of a dull, mild night, it may go out for want of draught Fifty years' housekeeping has taught me that what "E. F. G." asks about, can be done, and I insure success seven times in ten. Thus, let the evening fire burn rather dim, so that the heat of the fireplace and chimney shall have moderated towards bedtime. Then stuff the bottom of the grate, below the hot coals and ashes, with flat pieces of new coal, so as to cover the spaces between the bottom bars, and keep out air; gently beat down the surface of the fire, then throw on a big shovelful of real slack coal to cover the whole fire, next, two large lumps of coal on top; then run the poker down right through the centre to make a vent for smoke; shut all the doors of the kitchen to prevent draughts of air to the fire. Prepare a handful of chips, or a fire-lighter, placed near the grate ready for use in the morning, should the fire be only smouldering, not bright; the poker must then be used to open the coals, and let air through the fire. "Cannel" coal is a very blazy kind, not at all adapted for burning slowly; but very delightful to throw on top of a fire of a winter's evening, when you are telling ghost (or other) stories to the children.—H. O'B.

[60942.]—**Spirits of Wine.**—Yes, you can distil spirit from sugar or molasses. The fine is only £100 if the Excise catch you at it. Further particulars if required.—Doctor Medicinæ.

[60944.]—**Power to Grind Coffee.**—I know a man, a grocer by trade, who used to employ a boy to grind his coffee: now he does it by the aid of one of Gilbert's small coffee mills, driven by one of Shippey Brothers' little steam motors of half man-power, which I frequently see advertised in our Sale Column. The engine is placed over an American gas-stove, which is heated by a Fletcher burner. The coffee required for daily sale is weighed and placed in a hopper having a small glass tube to coffee mill, which feeds it gradually. When all the coffee is nearly ground, the outlet supply to hopper is closed, which forms contact and rings an electric bell as a signal to turn out the gas to prevent waste, the engine finishing the work while steam runs down; thus for about 2d. per day for gas consumed by this arrangement, the work which took the boy about three hours per day is done by this little engine, besides having the advantage of a good and cheap window advertisement, which shows customers that the coffee sold at this establishment is fresh ground. Perhaps this ingenious arrangement will suit "H."; should he only want to grind sufficient coffee for his own consumption, he will find it more economical to still use his own energy to grind his coffee by hand-power; but should he require to grind a few hundredweight per diem, by all means go in for a small engine, as it will be time, money, and energy saved for other purposes. I should hardly think the Seal engine powerful enough.—Nemo.

[60945.]—**Working Model.**—Why not buy a set of castings? You would then require piston rod of ⅛in. steel wire and slide-valve rod of $\frac{1}{16}$; crank shaft, say, $\frac{3}{16}$, with ¼in. bearings and ¼in. crank pin. For the rest, work to your own fancy.—T. C., Bristol.

[60947.]—**Chloride of Silver Cell.**—My idea of mixing lime with chloride of silver might not be considered scientific, but my reason for it was this:—In making hermetically sealed batteries for experiments, I was always troubled with gas which so accumulated that the battery burst in a few days. I tried the lime addition, and the results were better. Of course, it is of no use unless the battery is to be sealed. A single cell connected to a bell, rang it continuously for nine hours. On dissecting the cell, I found the chloride in a metallic state. I believe that with double the quantity of chloride it would have worked for double the time. Two cells in series worked the bell in the ordinary, intermittent manner for twelve months, and then died from the same cause—the chloride got converted into metal. In each experiment the cells had a little lime, and none of them burst. The number of cells which 1oz. of chloride of silver will be sufficient for really depends on how much is used in each cell, and on the diameter of the piece of silver foil on which it is laid. In the cells referred to (about the same size as "Holland" mentions) the paste of chloride and lime was laid on about ⅛in. thick. An ounce, at this rate, will go a long way.—Bobadil.

[60950.]—**Tricycle House.**—The damp is in the air. Varnish all the bright parts with clear white varnish; or else brighten them once and then keep them constantly slightly greased by wiping down with a rag and lard or tallow—preferably the first.—E. Conry.

[60950.]—**Tricycle House.**—My experience is that a tricycle keeps freer from rust in an open shed than in an inclosed house. Of course, when the atmosphere is moist and warmer than the metal the moisture will deposit. In an open shed where a free current of air blows over the machine, as soon as the temperature of the metal rises and that of the air falls the deposited moisture is taken up again. This may be observed on houses where the outside walls are frequently dry, while the inside ones are streaming with moisture.—Doctor Medicinæ.

[60950.]—**Tricycle House.**—Practically you cannot prevent dampness during the winter months in such an erection as you describe. The best thing to do is to rub the bright parts of the machine with a warm cloth, and then coat the nickel with vaseline. Of course the painted or enamelled parts require no such protection. Then cover the machine with a waterproof sheet if you have one—they can be bought cheap at army stores—and look, say, once a week to see that all is right. This advice is based on experience, as I have kept a tricycle for the last three winters in a wooden outhouse in my garden, and have maintained it in excellent order by following the above method. Rudge, of Coventry, advised me to use vaseline, and it has proved all that one could desire as a protective against damp, being cheap, easily put on, and non-evaporative. In fact, one coat is sufficient for the winter.—Lithium.

[60950.]—**Tricycle House.**—This trouble with damp is through no fault of the building. All the winter, but most particularly just in November and December, the most carefully constructed room will not secure bright machinery against rust. Whenever warm, damp weather succeeds cold quickly, the moisture is deposited on the cold iron; but if all bright parts be previously coated with oil, or painted with grease and whiting, all trouble with damp will be avoided.—F. R. Davis.

[60950.]—**Tricycle House.**—If "Tri." bores the holes it will do no harm; but to preserve the nickel-plating of his machine, if he will do as follows, he will have no trouble: Clean the plating well—I find the German pomade (a polishing paste) the best thing; then dip a rag in the ordinary petroleum, as burnt in lamps, and wipe all over—a little will do. When he wants it out, wipe off with clean rag. This is what I have done with mine for three years. Last winter it was stowed away four months; all the plating, with the exception of spokes, looks as well as new.—F. G. F.

[60951.]—**Electro-Deposition of Copper.**—I presume there is no deposit on to the anode caused by the mixture of tin and bismuth being electro-positive to copper. No doubt you would have seen this had it occurred, so probably the corroding is due to local action. Either the bismuth or the tin is of uneven quality, or have not got thoroughly blended in formation, so that local currents are set up between one part where there is an excess of one metal to another part of the same plate, where there is an excess of the other.—E. Conry.

[60952.]—**Lathe Matters.**—To drive a lathe or, indeed, anything, with an eccentric is quite impracticable. An eccentric can only be used to convert rotary into reciprocating motion; but not vice versâ.—F. R. Davis.

[60952.]—**Lathe Matters.**—If "L. H. R." lays down on paper the comparative sizes of an ordinary crank and of a corresponding eccentric, he will see that it would interfere with the convenient action of the leg in treadling, as well as to cause, when applied in this way, considerably more friction.—A., Liverpool.

[60952.]—**Lathe Matters.**—Your idea is not new; but, if adopted, mind your shins. Fancy an eccentric sticking out 6in. from shaft! If you want to do away with forging, have a straight shaft and cranks outside, also cranks on ends of treadle bar; but the usual way is by far the simplest. The eccentric would work all right.—T. C., Bristol.

[60952.]—**Lathe Matters.**—I have known this appliance used for transmitting small power, but discarded owing to its making more work by friction than the simple crank and chain with a momentum action of some sort, like those on a sewing-machine, or the chucks and gearing of a lathe.—E. Conry.

[60952.] — **Lathe Matters.** — An eccentric is equivalent to a crank having its crank-pin enlarged till it embraces the shaft. It can perfectly be used as you suggest, and has been so used. It is not, however, in theory quite so perfect, since if you use an eccentric, then the pulley in the treadle which takes the other end of the chain cannot well be much larger in diameter. Eccentric and pulley will, therefore, revolve at about equal speed, and you have only exchanged the friction of the ordinary hook on crank for the friction at the centre of the pulley plus the power required to bend the chain, so that probably you have gained nothing. With a crank and chain, since the crank-pin is about one-quarter the diameter of the pulley, that pulley will only make one turn to four of the crank, and as the rubbing surfaces at centre of treadle pulley move over one-quarter of the space, there should be a slight gain if the chain is in good order and bends easily. I dislike these chains: they lengthen and you have to put packing under the standards. I have nearly an inch of it under mine, and very likely the foot-board will bump the floor again soon; besides, they make a slight rattle just when you want to hear your tool cutting in a small hole.—F. A. M.

[60955.] — **Steam Hammer.** — The hammer will strike any blow, according to the hardness of the material struck—the less it gives the greater is the impact. All you can say is that the blow equals so many foot-lb. or foot-tons, as you please to express it, and this is absorbed in the small distance the material yields; pressure of steam 3,630lb. and of piston 560lb., or, say, in round numbers two tons falling 2ft. = 4ft.-tons. This you will notice is very different to $16 \times 2 = 32$ft.-tons of the falling condenser.—T. C., Bristol.

[60956.]—**Corn Thresher.** — The drum of a threshing machine can be balanced by placing it either on lathe centres, or the bearings resting on knife edges, and screwing on to the wood beaters pieces of flat iron, until the drum, when left alone, will remain stationary in any position, and to attain this end a great deal of patience is required. —F. R. DAVIS.

[60956.]—**Corn Thresher.**—Rest the spindle on two smooth bars, and balance drum so that it will remain in any position on the bars when placed truly horizontal. If there should then be any tremor when running, hold a piece of chalk against any true part of it, and then add a little weight on the side of the drum away from and opposite the chalk mark.—T. C., Bristol.

[60957.]—**Pitch.**—The number of teeth divided by the pitch gives the diameter of the pitch line. Thus: 60 teeth of 10 pitch = $\frac{60}{10}$ = 6in. diameter of pitch line. Conversely, the number of teeth divided by the pitch diameter gives the pitch number—thus: 60 teeth, 6in. pitch diameter = $\frac{60}{6}$ = 10 pitch. Box, on "Mill Gearing," published by Spon at 7s. 6d., is certainly the most practical book, but incomplete in some respects.—J. H.

[60958.]—**Crutch Slipping.**—A leather stocking to the crutch should be used, inserting a thick piece of indiarubber between the bottom and the leather.—S. HENRY SMITH.

[60958.]—**Crutch Slipping.**—A very complete answer to this query appears on p. 118 of Vol. XXV. (No. 629 of "E.M."). If "Magnet" cannot procure this No., and will advertise his address next week, I will copy out the reply referred to and will forward it to him. It would occupy too much space to reproduce it in these columns. —D. G.

[60959.]—**Chuck.**—No chuck having a scroll or spiral will do what you want. You require a die chuck, and the best die chuck I know of is the J. K. P. chuck made by the Britannia Company, and advertised several times in this paper. This costs 50s. with one pair of dies, and you would require about three pairs at 10s. the pair. Another plan would be to get the large-size "Oneida" from Churchill's. This is self-centring, and never lets go. Its cost is 45s. Both these chucks will hold 1in. Both hold by direct pressure of screws. —F. A. M.

[60960.]—**Bearings Heating.**—The position of the set collars on shafting has nothing to do with its heating, and they are, according to your description, in their proper place. The heating is probably caused by all the bearing not being quite in line. Carefully look to this, and write again if still troublesome.—F. R. DAVIS.

[60960.]—**Bearings Heating.**—See if your shafting runs true, and that drums are nearly balanced. I think that there may be some hammering due to the latter cause, which splashes all the oil out of the bearing, and hence heating. It matters little where the collars are.—T. C., Bristol.

[60960.]—**Bearings Heating.**—Perhaps it is the collars themselves rubbing on the sides of the brasses, but more probably something in the faces of the bearings. Have you had the brasses off and examined them? If not, why not sling or prop the shaft up, and take the central bearings out and examine them? You would probably get an idea from the state of the faces where the grind comes; perhaps it is only a little grit lodged somewhere.—E. CONRY.

[60961.]—**Chemistry.**—Dissolve oxide of cobalt in acetic acid, and add a very little nitrate of potassium; this will make an ink invisible when cold, and pink when heated. I know of no ink that could be rendered invisible by heat.—S. HENRY SMITH.

[60962.]—**Exhaust.**—It rots, and eventually crumbles away, the bricks and mortar. Carry the outlet end up to the open air, or through the brickwork into the open air away from the chimney.—E. CONRY.

[60962.]—**Exhaust.**—I have been using the exhaust steam pipe on the same principle as "Stoker" mentions for this last twelve months with great satisfaction; I find the chimney in as good condition as when I fixed tube. Take great care to fix the end of tube vertical in chimney, so that it does not affect the sides of chimney. The tube you connect it with to chimney must be at least ½in. larger in the bore than the delivery from port. By all means have the tube lowest in chimney, so that no water stands near exhaust port. Any further information on the subject I shall be pleased to give, if required.—EXPERIENCE.

[60964.] — **Rubber and Lead.**—The following is much used, and has a very good name as a cement, though I cannot myself vouch for its excellence: Dissolve 5 or 6 bits of gum mastic the size of a large pea in as much spirits of wine as to make a thick liquid solution. In another vessel dissolve as much isinglass (previously softened in water, though none of the water must be used) in spirits of wine as will make a 2oz. bottle of very strong glue, adding two small pieces of gum ammoniacum, which must be rubbed or ground until they are dissolved; then mix the whole with a sufficient heat, keep it closely stoppered, and, to use, set the phial in boiling water to soften it. This is said to unite anything, even to polished steel.—W. HOLDER, Newport, Mon.

[60966.]—**Accumulator.**—It suffers from the fault of all pocket accumulators: it slowly short-circuits itself inside, owing to the quantity of liquid held being so small that the plates are not always covered, aided by the fact that in the pocket cell the plates of necessity are in much closer connection with the sides, &c., than they are in the larger forms. To be really reliable all the pocket batteries require to be charged up only an hour or so before they are used. You would find it rather expensive working it as a De la Rue's cell, if you want to use it much; but if the use is not frequent, it would be much more handy in this form. Get two plates of unamalgamated zinc and silver respectively, the latter as thin as you like—silver-foil will do; cover this with a coating ⅛in. thick of chloride of silver, which you can best buy, and wrap it in very thin white flannel, backing the foil if necessary, on a piece of cardboard to stiffen it. Moisten well with saturated solution of salammoniac in water, and make up in the same way as an accumulator, adding a few drops of solution from time to time to keep the supply up. You would want three cells to get a good light. The action is very similar to that of a Daniell cell, silver being deposited on the silver plate, which gets continually thicker, being in the situation of a cathode.—E. CONRY.

[60967.]—**Ferrous Oxalate Developer.**—Put about one grain of tartaric acid to each ounce of used developer. Fill the bottles as nearly to the top as you can, compatible with getting the corks in without bursting. Place the bottles in a good light, and the developer will recover its energy. —S. BOTTONE.

[60967.]—**Ferrous Oxalate Developer.**—I have never used ferrous oxalate for developing enlargements; but I have used it very extensively for plates. My method of revivifying it is as follows:—I make a solution of tartaric acid, 1 drachm to 2oz. of water, I add to the used developer (say, half a pint) a few drops of the tartaric acid solution, and then expose it in a white bottle to sunlight for a few hours. It is then ready for use, and works as well as if it were freshly made. This renovating can be done over and over again. I have always obtained uniformly good results by the above method of reviving the developer, and I have heard some of my friends say that they could develop as many as 120 to 180 plates with one half pint of ferrous oxalate developer.—GLAUCUS.

[60968.]—**Bichromate Battery.**—1st. If five Bunsens are required to work your coil, it means that the coil requires an E.M.F. of nine volts to work it, since each Bunsen gives about 1·8 volt. Now no single-cell bichromate, no matter the size or number of plates, can ever give more than two volts; hence your two-gallon cell would not give a 4in. spark. 2nd. Chromic acid.—S. BOTTONE.

[60968.] — **Bichromate Battery.** — No; your one-cell, however large you make it, will only give just half the E.M.F. of two cells, however small; size in all carbon and zinc batteries only appertains to durancy. 2. Chromic acid is the best of the two, as you can use the spent liquid over again by mixing it with any spongy acid-proof substance dried into a paste, which can then be utilised as an element for a battery suitable for ringing your electric bells, should you desire it.—SHIPPEY BROTHERS.

[60968.] — **Bichromate Battery.** — One cell with zincs and carbons of any size whatever will not work a coil as well as two smaller ones joined in series, and containing carbons and zincs half the size. Doubling the number of cells doubles the E.M.F., and if 4in. sparks are wanted, the E.M.F. must be high. Large plates increase the quantity, not the force, of the current. The only advantage of a large bichromate cell is that, it remains constant longer than a smaller one, and this arises from the quantity of liquid it contains. I should advise the querist to halve his size of plates, and make two cells. Either bichromate or chromic acid will do: if for sustained action, the latter is best.—BOBADIL.

[60968.] — **Bichromate Battery.** — One cell, however large, would be inexpedient, for you would thus reduce the E.M.F. of your primary current from about 9 volts to less than 2, and you would not get enough current round the primary of your coil. If the primary had been specially wound for use with only one cell it might do; but as it is, you had better stick to the five cells in series. You can easily try the effect of one large cell by coupling your five cells up in parallel—all the zincs together and all the carbons together. You will thus have one large cell quite as effectually as if all the plates were in one vessel. If you want to save trouble and expense, why not use them as double-fluid bichromate or chromic acid cells? You would not then have to charge them so continually, but could leave them standing, and the cost would not be so great. The chromic-acid cell for preference. See back numbers.—E. CONRY.

[60969.]—**Fulcrum.**—If you do not require a long mathematical calculation, I may tell you at once that the proposed casting does not err on the side of weakness; but to be proportional should be either thicker or deeper where cored for the pin. Cast iron amply strong.—T. C., Bristol.

[60970.]—**Lathe Work.**—A suitable feed for roughing cuts on a bar of wrought iron of about 2in. diameter would be from $\frac{1}{20}$ to $\frac{1}{32}$ of an inch; that is to say, while the tool traverses $\frac{1}{8}$in. the bar would make about three revolutions.—J. H.

[60971.]—**Dynamo and Lamps.**—To MR. BOTTONE AND MR. EAVES.—The resistance of the two lamps in parallel is evidently below the critical point of working for this particular dynamo, so that the magnets do not get enough current through them. Put the two lamps in series, and you will probably get good results. But what resistance lamps are you using?—S. BOTTONE.

[60972.] —**Dewrance's Water Gauge.**— I always have these put to new boilers, and like them very much indeed. They will not require repacking for a couple of years, at least, according to the state of your water. If the plugs are not much worn you can repack them yourself with asbestos, and if they leak a little you can screw up the gland and tighten them.—T. C., Bristol.

[60972.] — **Dewrance's Asbestos Packed Water Gauges.**—These water-gauge fittings are the best ever introduced; they never set fast, and require no skilled labour to keep them tight. If leaky, take out the plug and remove all the asbestos, if required; grind in the plug, replace, and carefully repack, using a square brass rod to push the asbestos fibre in the recesses provided for the same. A little tallow will assist to keep them in good order.—P. F. OTTO, Liverpool.

[60973.]—**Double Engine.**—"Nominal" must give more particulars as to speed, and boiler pressure, and if any cut-off.—T. C., Bristol.

[60975.]—**Paraffin Oil or Coal Gas.**—Write to Mr. Paterson, of Alexander and Co., Kirkintilloch, for the details wanted. I can, however, from experience in my own family, say that for a private house the paraffin gas is superior to the coal gas—at least on a small scale. Existing gas works are easily altered to suit the new system.—B.Sc., Plymouth.

[60978.]—**Electric Lamp.**—To MR. BOTTONE. —I also have one of the 12-volt 10c.p. lamps from Messrs. Shippey. I find that I get excellent results by coupling six chromic-acid cells in series to each lamp. The Fuller battery is an excellent battery, which has an E.M.F. of 1·3 to 1·5 volt; but its resistance is rather high, so that the current is not nearly so large as in the plain chromic-acid cell. If you use pint bichromates, you will want about eight coupled up in series, zinc to next graphite, and so on; but chromic acid is better still.—S. BOTTONE.

[60981.] — **Cracked Wheel.**— Let the crack remain as it is, and rivet a strap underneath. You can tap studs in crack if required; but if not, let it remain open after riveting on the strap.—T. C., Bristol.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

60694. Phosphorescence, 163.

ORDERS have been issued for extinguishing the electric light in the tower at Hell Gate, New York Harbour, from and after December 1st. This action was based on the recommendation of the lighthouse board, and because of the constant complaints from mariners that the dazzling character of the light made it a detriment instead of an aid to navigation.

QUERIES.

[60982.]—**Chronic Inflammation of Nostrils.** —For some time past I have been suffering from this distressing complaint, and shall be very grateful if any of "ours" can tell me of a drug or course of treatment which will effect a cure. The insides of the nostrils are red and inflamed, and remain constantly so. Every few weeks, the inflammation increases, beginning with a smarting around the nasal orifices at the back of the mouth. This increases until the smarting has extended all through the nasal passages. Sometimes it extends over the back of the throat, producing hoarseness, and occasionally affects the lungs. As it is accompanied by an influenza cold, I am rendered half frantic between them. In a day or two, the acute inflammation subsides into the (now) usual state of low inflammation. I have tried iodine and eucalyptus without any permanent benefit. I also have cold baths every morning. Any suggestion thankfully received.—MISERY.

[60983.]—**Chloride Battery.**—Will some of our competent electrical friends please give their experiences of this form of battery? I refer to the one that consists simply of a porous cell with zinc rod in chloride of zinc and a carbon rod in the outer jar with a mixture of bichromate of potash and muriatic acid. I have been told one cell is equal to three Leclanchés. Is this so? Also, it will go three months without attention. At the end of this period, what happens? Are the solutions exhausted, or the rods covered with crystals from their respective solutions? Is this battery suitable for working bells? What I mean is this: does any local action take place when the circuit is open? The fact is Leclanchés have been doing the work, but other bells being added in circuit, more cells are required, and there is not room in the place alloted for them, so a more powerful cell must be used besides. I have the materials at hand for making them up at once if the general opinions are favourable. I have looked in back volumes, and can only find the cell mentioned once (and that for a special purpose), although I am told it is largely used.—M.M.I.SC.S.

[60984.]—**Boat Propulsion.**—I shall be obliged to any correspondent who has had actual experiences of the working of the most recent and approved methods of propelling boats, say, up to 20ft. long. I have spent some weeks in searching for the information in vain. I have heard of one style, built, I believe, upon the river Dart, in which the engine and boiler can be taken out and boat used as an ordinary yachts dinghy. Has a gas or hot-air engine yet been made to work satisfactorily and economically? Has anyone tried a treadle motion with propellor, of course not with a view of attaining any great speed, but as in whiffing in waters like the R. Fal, or other arm of the sea where this style of fishing is practised, and it is only just necessary to keep the boat moving along, which is usually done by keeping gently paddling along, both hands being thus engaged? If a treadle motion, similar to tricycle, could be adapted, it would leave both hands at liberty to manage the fishing line, or even two lines could then be used. Any information on these subjects will be gladly received.—HARRISON.

[60985.]—**Tides.**—Can any reader inform me the difference between the times of high tide on the Pacific and the Atlantic sides of the isthmus of Panama?—E. F. S.

[60986.]—**Waggon Grease.**—I would be thankful if one of my fellow readers would give me a recipe for making a good waggon grease.—R. J. C.

[60987.]—**Organ Query.**—I purpose building a single-manual organ to be played in a room 12ft. square and 8ft. 6in. high. Will one or more of "ours" be so kind as to give me a specification of one suitable? It must not exceed 6ft. 3in. high, and 2ft. 3in. deep, and 4ft. 6in. long. Would this scheme be at all suitable? Open diapason, to tenor C, 44 pipes; stopped diapason, bass, 12 pipes; keraulophon, 44 pipes; flute (for principal), 56 pipes? If not a good one, will any subscriber alter it for me? Is there any objection to the reservoir being fixed to bottom of windchest, similar to harmonium? If so, please say what. What height should reservoir 2ft. 6in. long and 1ft. 6in. wide be when fully inflated, and would this with two feeders be large enough to supply the above number of stops?—C. AND P.

[60988.]—**Loans to Building Societies.**—Would Mr. Weatherfield, or some other legal correspondent, kindly give me an idea on the following problem? A. takes up a number of shares in a building society, and builds a house, the society finding the money. B. lends money to the society, and the said society deposits the deeds, &c., of this house of A.'s as security. Now if the society becomes insolvent, can A. claim his deeds by paying up the balance of his shares in the society, or can B. retain the deeds or sell the house to recoup himself for the whole amount lent to the society? The society in their agreement with B. offer to make over at any time legally the deeds deposited with him as security for the loan; but the question is, can they do so if they become insolvent, or would A. be bound to lose his money as a shareholder in an ordinary limited liability company. I may say the society in question is incorporated under the Act of 1874. —CYCLOPS.

[60989.]—**To Mr. Wimshurst and Others.**—Having made one of your influence machines as described in the "E.M." a week or two ago, I should like to ask you a few questions relative to the working, as, although made strictly according to your instructions, it is not the success that I hoped it would have been. It was with the utmost difficulty that I could get it to work at all, and then only when warmed and induced by moderate friction with a warm duster. The results were fairly good; but the machine soon required re-warming. One very peculiar thing was that the machine would not start till the combs had been removed. Can you explain this? Our bosses were accurately turned in a lathe by a professed wood-turner; yet when the plates were fixed they did not run true. For joining the glass to the wood I used "diamond cement," which stuck exceedingly fast; but, in cooling, contracted the glass and cracked it. This it did to four plates. Is there any way to remedy this and to insure the plates running true? I should like to know why one of the brass balls on the discharging rods is larger than the other. I have inquired of many people in the electrical world, and, among others, one of your agents; but can get no satisfactory answer. Also, how is the electricity formed? Some say by the friction of the brushes; but this is manifestly wrong, as the friction is practically nil. I should say by the friction of the air between the plates. Am I right?—N. P. LONDON.

[60990.]—**Steel-McInnes Brake.**—Can any of your readers kindly explain to me how it is that the Caledonian Ry. Co. can, according to returns, work 28,000 miles with this system of brake, and yet have no engines fitted with it?—INQUIRER.

[60991.]—**Brakes on the North-Eastern.**—How many brakes are used on the North-Eastern, and what stock have they with two sorts of brakes?—INQUIRER.

[60992.]—**New Midland Engines.**—What has become of the new 1667 engines? Where are they at work? Is it true that they are having new steel boilers put on them to carry 160lb. of steam?—LOCO.

[60993.]—**Permanent Way.**—Mr. E. Woods, in his address the other day, told us at the Inst. of C.E. that a Mr. Hartley used stone walls to fix his rails on, and that in one case the chairs were fixed to solid rock. Wanted, the names of places were these plans were tried, and who first used stone-block sleepers on railways, and when?—PERMANENT-WAY MAN.

[60994.]—**Waggon Couplings.**—Do all the new waggon couplings work with loose couplings, or is there any plan to have a tight coupling without a man going in between?—SHUNTER.

[60995.]—**Brighton Engines.**—Do engines which are coupled in front, like the Gladstone, ride as smooth as those coupled behind, like 204? Does "front coupling" cause oscillation, or not, and what are the advantages of it, if any?—ENGINEMAN.

[60996.]—**Points and Crossings.**—On a straight double-road I want to put in a cross-over-road. Now, what is the extreme length, the distance from point to crossing, the angle of crossing, and the radius of curves in chains? Is there any simple book on how to lay out such work?—PLATELAYER.

[60997.]—**Cranks.**—A carriage-wheel radius (r) has a weight (w) clamped to its rim. The wheel rotates on an axis (not rolls on the ground) and is assisted by weight (w) during rotation from its highest to lowest point, and correspondingly retarded in rising from lowest point to highest point. A spoke is abstracted from the wheel and fastened as a crank to the hub, and weight w affixed to the end of this crank. Is there any difference in the retarding effect on the uprise of the wheel between the weight w clamped on the rim and the weight w affixed at the end of the spoke or crank? Centrifugal force to be excluded, or allowed for? Some of "ours" will kindly answer.—T. W.

[60998.]—**Cottage Range.**—I want to fix to chimney opening 30in. wide a range with oven on one side, but no boiler, open fire, having a fire-brick back, so that it can be replaced when burnt out. Can any reader inform me how such a range could be constructed so that it will heat the oven? The back of all the open fireplaces I have seen are made up with oven wing, and another iron part called the "sham," which soon burns out and cannot be repaired.—BRICK.

[60999.]—**Condensing Engine.**—I have one of Fowler's portable double engines, 14in., driving a large circular saw, and the discharge makes so much noise that I should like to put it to condense its own steam and to reduce the pressure. Would you kindly oblige me with information how to start to work to make it condensing? —A POOR SAWYER.

[61000.]—**Pipe Moulding.**—Would some of our readers give me a sketch how 4in. hot-water pipes are moulded to have flanges and to be ½in. metal, with a sketch of pattern and core box, to be greensand cores, with saddle placed in core for to take stud to hold down core, and if the cores are blackened or plumbago is used, and what kind of sand would you recommend?—H. S. H.

[61001.]—**Landscape, &c., Painting in Oil-Colours.**—Being very desirous of attempting to do a little landscape, &c., painting in oils, but having, as yet, not done anything beyond drawing and sketching with lead-pencil, would any of "the knights of the palette" (for I am sure there must be some amongst the numerous readers of "Ours") kindly give a few instructions in regard to the rudiments of the fascinating art of landscape painting in oils, as well as in the use of colours, vehicles, &c.? In using the colours contained in the collapsible tubes, is it necessary to use anything besides linseed oil, megilp, goldsize, &c., as the nature of the pigments require before placing them on the canvas, that they may be permanent? Being very remotely situated in a country village amongst the hills of Wales, and not within reach of placing myself under professional tuition, I cannot get the necessary information only through the medium of "Ours." Would any kind artist friend contribute a few articles on the above, or recommend a few good and cheap treatises or textbooks?—WELSH HOG-HAIR.

[61002.]—**Dynamo and Storage Battery.**—Will Mr. Bottone, or any other reader, inform me where I can get the following information? I want to light a room 12ft. by 16ft. with two 16c.p. lamps, or to about same power of light, and I want to make a storage battery that will maintain them for about 30 hours, and also a dynamo that will charge the battery. Will anyone give me details of battery best suited, as I want to drive it from a treadle lathe? What speed will it want to run at, and what time will it take to charge battery to maintain the lamps the 30 hours?—LUMSIE.

[61003.]—**Boiler Flue.**—I have a main flue at the back of boiler, 3ft. wide by 5ft. 6in. deep, which is arched with brick. Between the crown of arch and flooring tiles there is a space of 2ft. 6in., which is filled up with lime and rubble. Would it endanger the draught if I were to take away the arch and put metal girders across flue to carry a series of pipes in the 2ft. 6in. space, and cover over the top of water pipes with flue cover? Also, what is about the average temperature of a boiler flue, and would there be any danger of metal girders deflecting with the heat?—ENGINEMAN.

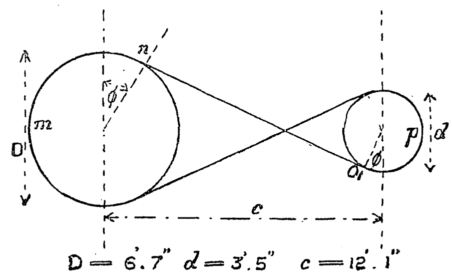
[61004.]—**Italian Language.**—TO MR. BOTTONE.—Will you kindly assist me to surmount the following difficulties—viz., how can I determine when the S at the beginning of a word is impure? How am I to obtain the present and past participles from the infinitive. These are rarely given in Italian grammars. What is the proper place for the adjective? I find it placed before and after the noun, and would like to know why it changes its position. When is it proper to leave out the personal pronoun before the verb, this being apparently a matter of taste? Is "coloro" or "englino" the proper word to use for the third-person plural pronoun? Some grammars give one and some the other. In translating the following sentence: "I go 'to the' friends of the lawyer" into Italian, why is "to the" expressed by "dagli," and not by "agli"? What grammar would you recommend, and what books to read by way of exercise? I may say that I know French thoroughly. I have travelled much in Italy, and can speak Italian sufficiently well to make my wants known; but I have a great desire to speak it grammatically. Any advice you can give will be gladly accepted by—A STUDENT.

[61005.]—**Combination.**—I have a great wish to add to my organette (31 reeds) a set of keys, so as to play with them as well as paper. Will some kind friend suggest a method, and, if not asking too much, send sketch for the same?—A. B. C.

[61006.]—**Influence Machine.**—TO MR. WIMSHURST.—I have made one of these machines with 16in. plates but no Leyden jars, the conductors being mounted on glass rods. Can readily obtain sparks between the terminals, but they are only about an inch long. Should they not be longer? I cannot notice any escape of electricity when working the machine in a dark room.—NIL.

[61007.]—**Polishing Whalebone.**—I should feel obliged if someone would tell me the material that is used for polishing whalebone, and if it can be done on a wheel. What speed should it travel, so that it can be done quickly?—BLACKSMITH.

[61008.]—**Length of Belting.**—Will any of your correspondents help me? In a work on belting I have, the following formula is given for obtaining length of a crossed belt (the enclosed diagram gives figures and measurements):—



Length—$L = 2\,(m\,n + o\,p + n\,o)$

$$= \left(\frac{\pi}{2} + \phi\right)D + 2\,c \cos\phi + \left(\frac{\pi}{2} + \phi\right)d.$$

$$= \left(\frac{\pi}{2} + \varphi\right)\Sigma + 2\,c\cos\phi\;(\Sigma = D + d) \qquad 2$$

$$\text{Sin}\,\phi = \frac{D + d}{2\,c} = \frac{\Sigma}{2c} \qquad 3$$

The length of the belt is obtained thus: Calculate the value of sin ϕ. From a table on natural sines and cosines "find the nearest values of cos. ϕ and φ, the latter being expressed in circular measure." Then eq. 2 gives the belt length. If ϕ is found or measured off the drawing in degress the circular measure of the angle is obtained by multiplying by 0·0175. I don't quite understand the meaning of the words between inverted commas, and I shall be glad of any assistance in the difficulty. If any of your correspondents would work the question out on the measurements given, and you can spare the space, I would be obliged.—OLDHAM CHAP.

[61009.]—**Induction Coil.**—TO MR. S. BOTTONE.—Will Mr. Bottone kindly say what length of primary and secondary I should require for a coil to give a 3in. spark in air? Also the proper size of each and length of coil? What number of quart-size bichromate cells would be required to work it full power?—REKLAW.

[61010.]—**Donkey-Pump.**—Will someone kindly say if the "Atlas" steam-pump made by Tangye Bros., or the "Special," made by Piggott, Birmingham, are suitable, and which is best, to feed two 25H.P. low-pressure boiler that work to 25lb. pressure, and to supply good pressure to hose for washing decks, or is a fly-wheel pump the best? How would either of above answer with steam cylinder 6in. and pump (double-acting) 3in.?—TUG-BOAT.

[61011.]—**Faulty Dynamo.**—Will some brother electrician help me in my difficulties? I have made a dynamo machine, and it will not work, as I cannot get a spark out of it; but as a motor it works well. Can you give me the reason? I don't know if I have enough wire on it for a dynamo; I have 4½lb. of d.c.c. wire. The F.M. is 7in. high, 3in. wide, and 6in. jaws. It has Siemen's armature, 2ft. 6in. I have tried the battery on it, and it is well insulated throughout. I have given it 1,700 revs. per min., and it will not give a single spark. Will you kindly explain it to me?—ANXIOUS.

[61012.]—**Annealed Zinc.**—What is the best way to anneal zinc after casting? Any information as to this will extremely oblige—METAL.

[61013.]—**Physics.**—In what proportion does the specific gravity of the principal elements decrease with an increase of temperature, or, in other words, what is the co-efficient of expansion in "mass"? Ganot gives the "linear" coefficient; but would this be as correct for the expansion in bulk as the specific gravity at different temperatures? Also, who is the publisher of "Woodward's Arithmetical Chemistry"? I have searched several catalogues without success.—EQUIVOLT.

[61014.]—**Chocolate Glaze.**—Will anyone kindly tell me how to make the chocolate glaze used by confectioners for glazing pastry?—PUZZLED.

[61015.]—**Magnets.**—I wish to make about 20 pairs of small field magnets whose pole pieces (when the wire is wrapped round) are only ½in. diameter. Will it make any difference to the "power of fields" if there is twice as much wire on one leg as the other?—MECHANIC.

[61016.]—**Organ.**—Would our invaluable and ever-willing friend "Uranium" oblige by giving width and length of C C and top G oboe reeds? Also same measures of clarionet reeds and the width of their four respective tongues, suitable for a chamber organ of 12 stops—four on great, four on swell, 2½ wind? I am thinking of making blocks and feet of hard wood, turned in the lathe, and tubes of paper or zinc. Also say which is best—vertical or diagonal notches in flue pipes, as the latter seems to me to have a tendency to drive or direct all the wind on one side of the mouth.—J. H. C.

[61017.]—**Incandescent.**—Under the heading "A New Incandescent Lamp," the following appears in one of our "weeklies": "An incandescent lamp which requires no vacuum in the globe has been invented in Germany. The wire used is a mixture of conducting and non-conducting elements, the latter preventing the former from melting." Could anyone give us correct information about this lamp—what the filament is made of, &c.?—LAMPS.

[61018.]—**Optical Lantern.**—I am making a lantern, and find that with the same condensers I can place the lenses, say, 6in., 9in., or 12in. from the condenser, provided suitable lenses are used. Why is this? If 6in. is the proper place to catch the right number of rays of light from the condenser, how is it that I can get, or appear to get, the same number at 12in.? Can I have as good lenses for the long focus as for short, or must I use single lenses for long focus?—LIME LIGHT.

[61019.]—**Brazing.**—Can any of our readers give me any hints on brazing steel saws? They are an inch broad. I should also like to know whether there is any apparatus for performing the same.—G. M. W. W.

[61020.]—**Electrical Paper.**—I want a solution in which to soak paper, so as to make it a conductor of electricity when dry. Also want to put a surface on paper which will conduct electricity. I have some magneto generators, which I want to convert into motors. What size wire shall I wind armatures with, so as to get best results with, say, 20 cells, gravity battery? and please give arrangements of cells. Armature sizes, 3in. long, 1⅜ diam, Siemens H.—LUX.

[61021.]—**Induction Coil.**—Core, 8½in. long, ⅞in. thick; primary coil, 7in. long. Query: (1) Whether 20 or 22 iron wire for core; (2) whether 16 or 18 double silk-covered wire for primary, the number of layers being two; (3) whether 36 or 38 double silk-covered wire for secondary, and the quantity, which will be wound in two sections, divided by a piece of millboard soaked in paraffin-wax, ⅛in. thick; (4) thickness of insulation (which will be of paraffined paper) between each layer of secondary, and between primary and secondary coils; (5) full length of spark to be expected?—L. W. WILLIS.

[61022.]—**Leather.**—Can any of your numerous correspondents inform me of a rapid means by which I can extract the colouring matter from leather? I have had a piece of the best English-tanned leather in water for the last three weeks, and, no matter how often I change the water, it still turns red after standing a few hours. Is it necessary that I should wait, perhaps months, till I can keep the water clear?—J. P.

[61023.]—**Reducer.**—Good formula wanted for above, to reduce parts only of a negative by aid of a camel-hair brush.—CROW'S-NEST MAN.

[61024.]—**Sensitising Drawing Paper.**—Formula wanted for sensitising drawing paper, such as Whatman's. Does such paper receive previous preparation in any way?—CROW'S-NEST MAN.

[61025.]—**Platinotype Printing.**—Does the quality of daylight matter in printing in above process, or can equally good results be obtained in all states of daylight and time of year?—CROW'S-NEST MAN.

[61026.]—**Smoking Fish, &c.**—Could any reader inform me how to keep the sawdust smouldering, as, unless I keep red-hot irons in it, it goes out?—ARCHER ASHBY.

[61027.]—**Single-Lens Eyepiece.**—Would "F.R.A.S.," or Mr. Sadler, kindly say form of single lens eyepiece he would advise? I see Mr. Webb, in "Celest. Objects," says it is better to have the lens convex side to the eye. I certainly find a single lens most useful for certain purposes, as I have slow motion.—H. A.

[61028.]—**Etching.**—I have a difficulty in getting the ordinary fluoric acid to bite. Is there any way of increasing the etching power of the acid on glass, or is there any special preparation of fluoric acid for this purpose? I have tried the principal chemists in London.—C. W. ELLACOTT.

[61029.]—**Gourd Drinking Cups.**—I have heard of, and want to make, cups of gourds. Will some of "ours" say how to proceed, how long to be kept to dry, if fitted with feet or turned off, and how chucked, &c.?—CAZENOVE.

[61030.]—**Cleaning and Tapping Brass Nuts.**—Will any reader inform me how to clean up outside and tap hexagon ½in. brass nuts, as I have a quantity to do, and wish to do several together, if possible? I have a lathe and shaping machine at my disposal.—CAPTAIN CHRISTY.

[61031.]—**Brass Boiler.**—What pressure could a brass boiler of ⅛in. in thickness and having brazed seams stand? Also give me a good description of Leitch's rotary engine.—NEILSON.

[61032.]—**To Mr. Bottone.**—What size and quantity of wire should I need to wind a dynamo double the size described in your book? How many 5c.p. would it run, and what power should I require to work it?—G. P. R.

[61033.]—**Panorama.**—Will some correspondent kindly give me a description (and sketch, if possible) of the rolling gear of a small panorama? The continuous canvas is 6ft. wide and about 60yds. in length.—HENRY W. WEBB.

[61034.]—**Boiler.**—To "T. C." OR OTHERS.—Will you explain the following? On the feed-pipe of a boiler there is a valve with the words, "regulate the lift of this valve so as to give a constant feed." A sketch if possible. 2. There is a row of economisers behind boiler. Now, how is the water run in these? Does it require two pumps, one to force the water into corners and the other to draw it from corners to force it into boiler? Or will one pump do? If so, where should it be placed? Please state fully, as I have to take charge of these shortly.—ONE WILLING TO LEARN.

[61035.]—**Re-cutting Fret Saw.**—I have a large fret saw with four of the teeth broken. I should feel thankful to some kind reader if he could instruct me how I could re-cut it for a new set of teeth. I think I could cut the gullets out with a small emery wheel in the lathe; but how am I to get the old teeth all cut out in a straight line?—YOUNG TURNER.

[61036.]—**Observatory Shutter.**—Will someone kindly help by suggesting a means of working the above? Size, 9ft. long, 1ft. 6in. wide at top, 3ft. 6in. wide at bottom, of wood, with 4in. by 1in. styles, and rails with ⅝in. matchboarding, covered with painted calico; roof, conical (with a cap at top which lifts), on a 12ft. drum, the shutter to open and lie flat on adjoining portion of roof. The shutters originally stood upright when open.—C. T.

[61037.]—**Indigo-dyed Serge.**—TO MR. ALLEN.—In a sample submitted to me, I found an aniline blue. Is such a dyestuff ever legitimately added? If so, to what maximum extent? What quantity of indigo relative to the weight of the cloth, presumably of good quality, may one expect to be present? By a "practical" man, it was asserted that woad had been used. By this I suppose was meant that the cloth had been dyed in a woad vat. Now, seeing that woad is only used to start fermentation, and is thereby split up into indigo and other products which are not dye-stuffs, I cannot conceive how he was able to decide the point — certainly not chemically, I should think.—B. B.

[61038.] —**Ampere's Theory.**—When reading up Ampères Theory of Magnetism, I was much struck by the fact that he assumed an electric current to circulate round each molecule of a magnetic body. He did not (as far as I can learn from the textbooks I have read) seek to point out the origin of these tiny currents. Now, as every effect must have a cause, I have often tried to build up a theory which would satisfactorily explain their origin. I have succeeded in making out one, which appears to me to be good, and I would fain lay it before the readers of the MECHANIC for criticism. However, before doing so, I should like to know if any of "ours" have already seen an explanation of these currents, and, if so, in what work?—J. J. H.

[61039.]—**Electric Light Battery.**—Is there a battery (non-fuming) which will give a good light to, say, ten 15-candle lamps constant for 60 hours? I was in Messrs. Burrows and Watts', Soho-square, a short time since, and saw there a number of incandescent lights worked from a lot of 1ft. (cubic) cells, which I was told would last 70 hours. Can anyone give description and account of its performance? I want the light for a private billiard room.—THOMAS PLUNKETT.

[61040.]—**Levelling Glass Cells.**—What is a good thing to run into the bottom of glass battery cells to make them level, so that the porous cells may stand firmly? I have tried plaster-of-Paris; but the solutions seem to dissolve it. I have also tried bedding a glass plate in the plaster. This does for a time, but eventually works loose.—MEM.SOC.ENG.

[61041.]—**Joints in Hot-Water Pipes.**—Will any of our engineers kindly give me a little advice? I have a low-pressure cast-iron hot-water boiler, with tubes. The fire passes between the tubes and round them, likewise on the socket joints. What is the best material to make the joints with, and how made? I have some spongy cast tubes. Can they be made water-tight for low pressure? They are ⅝in. thick.—UNDER FITTER.

[61042.]—**Seeds.**—Having commenced making a collection of seeds, I should be very pleased to know how to preserve the full shining appearance of large seeds, such as chestnuts or acorns. I have some acacia seeds many years old, about the size of sweet peas, but elongated. They still retain vitality, and are as bright and full as when new. They are half red and half black. Is it their natural colour? Should be also much obliged to any one of "ours" who would give me the names of books on the subject.—W.

[61043.]—**Power of Gas-Engine.**—What will be the power of gas-engine on the compression principle, cylinder, 3in. dia. and 3in. stroke, rev. 450, with 60lb. fly-wheel?—C. J.

[61044.]—**Band Saws.**—I have a band saw running daily at an ordinary speed. Would someone tell me the average life of one of these, as I find they will not exceed two months? They have to cut all hard woods, such as English oak and ash and elm, from 2in. to 8in. thick. I find they give first in bottom of the teeth. The employers think it a short period.—WOOD SHOP.

[61045.]—**Spring Motor.**—I want to run a spindle, carrying 1lb. weight and running freely, 2,000 revs. a min. for six hours. Please say what power of spring (clockmaker's gauge) and arrangement of wheels is required.—M. NEWMAN.

[61046.]—**Logarithms.**—Why did Napier take 2·71828 for the base of his system of logarithms? Also, will some one inform me how, in the following formula, (2) is obtained from (1)?

$$z = \frac{2}{n^3 - 3n} \cdot \frac{1+z}{1-z} = \frac{n^3 - 3n + 2}{n^3 - 3n - 2} = \frac{(n-1)^2 (n+2)}{(n+1)^2 (n-2)}$$

$$\therefore 2 \log. (n-1) - 2 \log. (n+1) + \log. (n+2) - \log. (n-2) \ \ldots\ldots\ldots (1)$$

$$= 2\,\mathrm{M} \left\{ \frac{2}{n^3-3n} + \tfrac{1}{3}\left(\frac{2}{n^3-3n}\right)^3 + \tfrac{1}{5}\left(\frac{2}{n^3-3n}\right)^5 + \&c. \right\} \quad (2)$$

I fancy an answer to one of these two questions will answer the other also. As the same construction is constantly recurring in mathematical formula, I should be extremely obliged for a lucid reply.—EQUIVOLT.

[61047.]—**Multiplex Copying-Ink.**—In a former number this ink was said to be prepared from one part of violet methylated aniline to seven of distilled water and one of alcohol. Is the methylated aniline a fluid, and where can it be obtained? I have tried the powder, but do not know how to proportion it to the water. Can any of your readers favour me with a clear and well-tested recipe, and also give me the best recipe for the preparation of the jelly? And say whether Anderson's prepared paper in lieu of the jelly is satisfactory—whether it will keep for a long time, and how it is prepared?—SIGMA.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

***** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.**

The following are the initials, &c., of letters to hand up to Wednesday evening, Nov. 24, and unacknowledged elsewhere:—

JOHN MACLEAN.—C. Penruddock.—A. Francois.—Fowler, Lancaster, and Co.—S. R. Bottone.—B. J. Hopkins.—A Fellow of the Royal Astronomical Society.—E. Conry.—H. Sadler.—C. Gunn.—E. F. S.—Stoker.—J. T. Garbutt.—J. W. R.—A. B. C.—Novice.—F. R. C. S., Eng.—Cedar.—Brian Boru.—W. H. Thurlow.—A. F. Shakespear.—E. R. Dale.—Omnium Gatherum.

J. N. H. (If any one can be said to have "invented" the locomotive, it is Richard Trevithick; but Cugnot, in France (18th century), and Oliver Evans, in America, are respectively claimed by those who regard facts through tinted spectacles. The printed letter you forward has been written in ignorance of the facts, for it is certain that Trevithick turned the exhaust steam up the chimney as early as 1804. Hedley, Hackworth, and G. Stephenson all helped to improve the locomotive; but there is no doubt that Stephenson is correctly described as the "father of railways." To speak of Stephenson or Hackworth as the "inventor" of the locomotive would be absurd. See pp. 404, 428, 475, 504, 549, Vol. XXXIII., or the "History of the Invention of the Locomotive," published by T. West, North-road, Darlington.)—MACHINIST. (How can it be when it is not yet completed? Probably it will be published in book-form.)—TERRANOVA. (Oxalic acid will certainly remove any iron ink; but it is necessary to bleach after its application with weak solution of chloride of lime.)—J. H. S. (Stand it on thick rubber sheeting, and line any adjacent wall with canvas papered over.)—H. G. (Coal-tar naphtha is the natural diluent of pitch. It is sold under the name of mineral naphtha.)—FRETOMANIA. (The Britannia Company, Colchester, have one which answers the description. Procure their catalogue, and also that issued by Churchill and Co., Cross-street, Finsbury.)—INQUIRER. (You could change it to a bichromate, of course; but see the indices. Bunsens always fume; but surely you can keep it outside the house.)—DR. HALL. (See indices for many articles and notes on the subject. For instance, No. 1092, p. 533; No. 1005, p. 380; No. 943, p. 158. See an article in last number about the Foraminifera.)—J. G. (If it is so hard, it has probably perished. Try what effect gentle warming has. Stop the leak with a piece of calico and solution of indiarubber or guttapercha tissue wrapped round.)—OLD LONDON. (Nicholl's "Theoretical and Practical Boiler Maker," published by the author at Blackpool; but there is no treatise specially devoted to boilers of the kind you refer to. Indeed, makers themselves are only experimenting.)—H. S. (Probably Mr. J. E. Aylmer, Leadenhall-buildings, E.C., can help you. He was the representative of M. Trouvé at the "Inventions.")—MAX. (Unless an acoustic telephone will do, you must apply to one of the companies. See advertisements.)—IGNORAMUS. (For coating iron with lead see p. 481, last volume. Coating with zinc is called galvanising, the iron being dipped into the molten zinc. The electrical process was abandoned years ago.)—ALOOK. (Saws, mitre block, shooting-board and plane, hammer, bradawl, nails, vice, and clamps.)—INKPOT. (1. No danger of "lightening." 2. The "Mechanical telephone" was described in No. 1061, p. 447.)—J. T. (Must be more explicit. Some moulds are made of wax, others of gelatine, others again of sulphur. Say what it is you want to do.)—C. F. (Squeeze them out, or rub in paraffin oil. 2. The law is not settled; but the local authorities can prevent their erection. 3. Scandinavian red fir is generally used. The duration depends on local conditions. 4. Yes. 5. No remedy, except lacing them together at frequent intervals by some non-conductor, wrapping the insulators with vulcanised rubber, or inclosing the wires in vulcanised tubing.)—AMŒBA. (Huxley and Martin's "Course of Practical Instruction in Elementary Biology," Macmillan, price 6s.)—LOGARITHM. (Probably you mean Haskoll's "Engineering Fieldwork." If so, that is published by Crosby Lockwood and Co., Stationers' Hall-court, E.C. There is a "Field Book," by the same author.)—G. B. G. (Spretson's "Treatise on Casting and Founding," published by Spon, 125, Strand, W.C., may suit.)—SCHEMER. (For how to make a smith's fan see No. 872 specially, and Nos. 861, 862, 886, 915.)—IGNORAIN. (Read the description again, and see if you have not omitted to notice some point of detail.)—COUNTRYMAN. (Try some of the recipes given

in back volumes. A simple and fairly effective method is to rub the wrong side of the cloth with pure beeswax until it is completely covered with a thin coat; then pass a hot iron over it, and brush the cloth whilst warm. Paraffin wax melted up with a little linseed or other drying oil, and cast into blocks, does as well as beeswax. To make waterproof calico damp the fabric, and coat with linseed-oil.)—A. E. PITT. (You are not obliged to patent it or register it; you can use any trade mark not already appropriated, but if you want to protect it you must register it.)—DUSTY MILLION. (Really, such questions should be sent to a sporting paper. Lord Falmouth's colours are—first, black, white sleeves, red cap; second, white, black sleeves, red cap; and third, rose upon ermine, black cap, gold tassel. 2. G. Barrett rode Farewell when she won the One Thousand.)—PUZZLED. (There is only one satisfactory way. Cover the articles with the black varnish, and put them in a "stove" to dry and bake. See p. 36, Vol. XXXIV., and the indices. 2. As to case-hardening, see answer to "Amateur, W. L.," last week, p. 271, and the indices.)—GAS-FITTER. (Use all Leclanchés. Procure a catalogue from Gent and Co., Leicester, or Mr. Blackwell's list, Chapel-street, Liverpool. Look through back numbers.)—M. R. (You will find an illustration of the details of an electrical "sign" in No. 886, p. 41, or a description in No. 790, p. 239. Little reflectors are suspended so as to swing in holes in a plate which is put into vibration by means of a magnet and a battery, on the same principle as an electric bell is made to work.)—A YOUNG ENGINEER. (If you cannot refer to back numbers you will find a full description in Mr. Jamieson's recently issued "Textbook of Steam and Steam Engines," and also in many of the manuals. It is known as a Prony brake, or absorption dynamometer.)—J. BURLEY. (They are sharpened by rubbing with emery and oil on a strong flat glass plate. If there is a machine, no doubt the wheels would run horizontally. See Hints No. 4.)—STEENIE. (The Australian sovereigns are nominally of the same standard in fineness, and the same weight and value as those issued from the Royal Mint. Practically they are identical in value; but if there is a difference it would no doubt be in favour of the Australian coin, which has silver instead of copper in its composition.)—CHEEKOS. (Take plenty of exercise, and avoid fattening diet.)—W. L. (See indices of back volumes, and recent numbers.)—IGNORANT. (Tire cements are made in various ways; but as good as any is made by mixing three parts of Stockholm pitch, 3 parts of resin, 6 parts of crude caoutchouc, and 12 parts of oil of turpentine by the aid of heat. Guttapercha, pitch, and turpentine make another good cement. As a rule, it is cheaper to buy such a cement than to make it in small quantities.)—CAZENOVE. (Yes, if the tap leaves the passage fully open. There is a slight difference after a time, as the burner becomes hot, and therefore expands the gas slightly, so that less passes than when the burner is not alight.)—T. BRIGGS. (Must explain fully. It is illegal to deface coins and tokens of the realm. What is meant by "enamelling"?)—ELECTRIC LIGHTER. (We have frequently stated that a Daniell battery is not suited to electric lighting purposes. If the electric light is wanted continuously, it may be economical to use a Daniell. You will have seen what has been said recently.)—METER. (If correctly drawn it reads 131,000 cubic ft.; but we never saw an index like it. The figures in the centre dial are the wrong way. Look again. All the dials surely are not alike. The small dial is for experimental purposes, to detect leakages, &c. One revolution means 2 cubic feet consumption.)—ETIENNE. (Try Messrs. Dawkins, 17, Charterhouse-street, E.C.)—G. T. T. (Kindly refer to the numerous replies about dynamos, which have appeared in the last six volumes.)—M. A. B. (See indices, and recent back numbers.)—H. BERT. (The gas-engine has been frequently described in back volumes. For a general description, see p. 92, No. 1071, p. 155, No. 1021, and the index to Vol. XXXIX.)—H. H. (Get Britten's "Watch and Clockmaker's Handbook" from the author at the Horological Institute, Northampton-square, E.C. 2. Try a mixture of red lead, flour, and sugar.)—AMATEUR, Halifax. (Do you mean bronze varnish, or "browning," such as gun barrels? Methods of doing both in back volumes. One method of bronzing the actual surface is to expose the articles to the vapours of a heated mixture of strong hydrochloric and nitric acids for a few minutes, and then heat the articles up to 650° Fahr., or so. When cooled, rub over with vaseline. Acetic acid is also used in conjunction with the above-named acids.)—HARRY. (Wood-engraving is practically replaced by the photo.-zinco. processes. Still, there is "always room at the top"; but at least 75 per cent. of those who earned a living six years ago by wood-engraving have had to adapt themselves to some other work. Messrs. Lockwood and Co., Stationers' Hall-court, E.C., publish a handbook of the art.)—JACK. (No, why should it?)—WALTER E. WEBB. (We do not know; but the Finsbury Technical College is not so very far from Hackney, and you would get the best teaching there. The college is not much more than a mile and a half from the Triangle.)—THOMAS SMITH. (We do not reply by post. 1. An oil would circulate. 2. We do not think there is; but what is your object? Water is the best thing. 3. Do not know what you mean by "40 degrees of steam," but steam at 40lb. pressure on the sq. in. has a temperature of 287° Fahr., and that would be approximately the temperature of the water in a boiler under such pressure.)—F. R. C. S. (In such circumstances a hot-air engine would be best, unless you can obtain petroleum cheaply, and like to try one of the new petroleum engines. A hot-air engine is rather large for its power, but it is practically no trouble, and wants only an occasional supply of fuel. A windmill would be useful.)—C. C. (Procure the pamphlet published by Gent and Co., Faraday Works, Leicester.)—W. T. CADMORE. (For incubators, see No. 1007, p. 425, No. 1009, p. 471; No. 935, p. 562; No. 908, p. 553; and the indices of back volumes.)—A., Liverpool, RAYMOND BROWNE, F. A. M. (In type.)

A BEGINNER.—If in your second attempt at 1,018 you mean 1. Q-K R 3, R takes Q. Your first attempt we have shown to you is wrong.

BLACK PAWN.—Revised version of two-er received with thanks.

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve Months, Post Free to any part of the United Kingdom. For the United States, 13s., or 3 dol. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office Order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. JAMES W. QUEEN and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII., XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX., XL., XLI., XLII., and XLIII., bound in cloth, 7s. each. Post free, 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post free from the office (except index numbers, which are 3d. each, or post free, 3½d.).

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XL., and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

For every succeeding Eight words	0	6

*** It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions and in cases where the amount sent exceeds One Shilling, the Publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O.'s.

The address is included as part of the advertisement, and charged for.

Advertisements *must* reach the office by 1 p.m. on Wednesday, to insure insertion in the following Friday's number.

NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

OUR EXCHANGE COLUMN.

The charge for Exchange Notices is 3d. for the first 24 words, and 3d. for every succeeding 8 words.

Good Value Offered (cash or instruments) for all kinds of sound or repairable Scientific Appliances.—CAPLATZI, Science Depot, Chenies-street, near British Museum. Established 1862.

Wanted, **Photo Apparatus**, wet or dry, cameras, sundries, &c., in exchange for Microscopic or Magic Lantern Slides.—Apply, PIGGOTT, Chemist, Huddersfield.

"**English Mechanic,**" 500 numbers, from 593 to 1093, with indices, clean and perfect. What offers in exchange?—STUBBIN, Buckshorn Oak, Alton.

Tricycle, Coventry lever, double steering, two track, adjustable pedals, cushioned seat, good condition, newly painted. Offers.—FORD, 75, St. Paul's-road, Camden, N.W.

What offers for complete **Parts of Six Tricycles,** rear steering, partly made, rims drilled, hubs drilled and tapped, 6 wheels made, all lugs brazed on, cranks finished; when completed eminently suitable for hiring out; good winter occupation ready for next season. Wanted, one horse-power Gas Engine, suitable for dynamo. Other offers requested.—BLACKFORD, Mathinist, Windsor.

Steam Engine, powerful one-horse, Washing and Wringing Machine combined, Hand Sewing Machine, small Boiler on wheels, Shop Stove. Exchange.—MILLER, 1, Melbourne-square Brixton-road, S.W.

Lathe, back motion, expanding chuck, 10in. centres slide-rest, no bed; for Vertical Engine and Boiler, 3 H.P.—WM. SKINNER, 26, High-street, Elgin, Scotland, N.B.

"**English Mechanic,**" 5 Vols., Nos. XXXVII. to XLI., inclusive, for sale or exchange. Should like Mr. J. T. Sprague's "Electricity," latest edition.—J. GRAY, 10, Pancras-road, N.

A 10-stop Pipe **Finger Organ** for an American Organ. Space required.—Address, EXCHANGE, No. 83, Stanhope-street, Newcastle.

"**English Mechanic,**" to date, 44th volume, complete and clean. Offers in scientific articles.—Address as above.

Wanted, small **Rolling Press,** suitable for zinco-transfers. Offers.—BEAVEN, Warminster.

Wanted, small **Litho. Press,** suitable for amateur. Exchange Lenses, &c.—BEAVEN, Warminster.

Model **Vertical Engine,** cylinder 2¼in. by 1½in. Would take a Slide-rest, or anything useful for a 2½ centre lathe.—W. MARTIN, 25, Willow-grove, Plaistow, Essex.

Electro-Platers.—Brass Moulds for casting Britannia-metal Cruet, handle, feet, supports, weight 30lb. Samples sent. Exchange for Gramme Armature (Dynamo Castings, Xero). Value 70s.—HEMMING, 165, George-street West, Hockley, Birmingham.

Electric Motor and an Edison Electric Pen for exchange. Offers invited. Value 15s. and 42s. respectively.—BRAUN, 1, Kilburn-square, N.W.

Wanted, **Launch Boiler,** Engine, Propeller, &c., for 16 by 5ft. boat. Can offer lot new Hammers, Axes, Planes, Ironmongery, Cutlery, &c.—HARRISON, Devoran, Cornwall.

Youths' **Tricycles,** Meteor pattern, 3 machines, part finished; 1 cwt. loose fitting. Exchange good Lever Watch, offers.—Letters to W. SMITH, Bilston-road, Wolverhampton.

Model **Boiler,** 10¾ long, 6½ wide, all copper, tubular, Locomotive shape, with internal firebox, safety valve, taps, &c. Offers in exchange.—H. BUDD, Stoke-road, Gosport.

Leading Screw and **Change Wheels,** suitable for 5in. Lathe, and set suitable for 7in., in exchange for anything useful.—R. SMITH, Fazackerley-street, Chorley.

Blocks and Rope, three sheave, 1¼ rope, very good condition. Exchange good Opera-glass or offers.—R. SMITH, Fazackerley-street, Chorley.

Dynamos, two small, and one Motor. Drill Chuck, with plug, nearly new. Want 2-jaw chuck or offers.—REV. HERVEY, Hartley, Alton, Hants.

"**Marks on China,**" by Chaffers, published at 42s. Out of print; new; Set of eleven Pool Balls, in basket; for scientific apparatus.—SOUTHWELL, Chemist, Boston.

Half-plate **Camera and Lens,** by Lancaster, 2 double dark slides, tripod, case, drop shutter, &c. Value about £5. Will take £3, or exchange for good 52in. or 54in. Bicycle.—Full particulars to JAS. CHISHOLM, 390, St. Vincent-street, Glasgow.

Concert **Flute** (cocoa), eight German-silver keys, for Telescope, Camera, or offers.—T. K. MELLOR, Cloth Hall-street, Huddersfield.

What offers for any of the following?—**Photos.** of Actresses, Celebrities, &c., Pike Rod, Meerschaum, Lantern Slides, views Irish scenery.—EDWARD HUGHES, Graigue, Kilkenny.

50in. **Bicycle,** new, Bown's Æolus ball bearings to front wheel, cone to back, cowhorn handle bars, 60 spokes, splendid machine. Part exchange. Approval.—F. GRIFFITHS, Wednesfield Heath.

Portable **Bichromate Battery,** three cells with ratchet arrangement to lift plates, best make, in polished box, very powerful, good condition; cost £1 12s. 6d. Exchange for Electric Motor about same value, or other apparatus.—A. H. ULLYETT, Calham House, Folkestone.

Horizontal **Engine Patterns,** 2½ by 5, complete set with drawings. Made by an experienced man. What offers?—MACKAY, 48, Stanley-terrace, Lincoln.

Wanted, 6in. back-geared **Lathe,** complete, for 52in. Bicycle, nearly new, to value £9 10s. Not ridden 50 miles. Cost £12 10s.—GEO. E. R., 31, Farley-road, Norwood Junction.

Seven volumes of "**The Engineer,**" range from 1860 to 1867, well bound and clean. What offers?—W. MOSS, 18, Croton-place, Armley-road, New Wortley, Leeds.

Lantern, 3¼in. condenser, single; also some splendid Slides, astronomy, &c. Exchange.—IHOW, Lenzie, N.B.

Neat **Coil,** ⅛ spark, with battery; 8 "Crosby" Batteries, 5 c.p. Lamp, Wire, Chromic Acid. Offers, value 13s. 6d.—School House, Warborough, Wallingford.

Pigeon Hole Cupboard wanted.—R. BAKER, Sudbury-road, Thornton Heath.

NOTES ON THE CHURCH ORGAN.
I.

By GEORGE ASHDOWN AUDSLEY, F.R.I.B.A.

FINDING that my "Notes on the Chamber Organ" have met with warm approval from the readers of the ENGLISH MECHANIC interested in organ matters, I feel emboldened to submit, for their consideration, a few remarks on the subject of the Church Organ. On first thoughts, the subject may appear to be one calling for little comment; for it is generally believed that all that can be done has been done to render the Church Organ a perfectly satisfactory instrument. While I am free to admit that the Church Organ, generally speaking, is not, at the present time, in the same neglected condition as we find the chamber organ to be in, yet I consider that there is a very general misconception with reference to the proper appointment of organs for churches; and that a little more thoughtful attention given to the matter would lead to considerable alteration and a substantial improvement in instruments intended for the accompaniment of sacred song. It is a noteworthy fact that, notwithstanding the great numbers of Church Organs which have been built during the last quarter of a century, it is quite a matter for congratulation to find one which can be pronounced entirely satisfactory. Several causes have led to this state of affairs; some attributable to the blunders of architects; some to the want of knowledge and skill on the part of the organ builders; and some to the total ignorance, on all matters relating to the appointment and construction of organs, of those persons who, through accident or other circumstances, have been deputed to decide on the specifications to be adopted and the manner in which they are to be carried out. Perhaps, after all is said, the most potent agent which has been at work in causing the failure of the generality of Church Organs is the misdirected ambition on the part of consequential "organ committees" and enthusiastic organists.

I have been speaking of the past; but all the causes of failure, above alluded to, obtain at the present time. Before proceeding further, it is advisable that I should enlarge somewhat on these causes of failure.

Firstly: Architects, in their carelessness, if not complete ignorance, regarding the requirements and construction of organs, very frequently fail in providing proper accommodation and suitable localities for their reception. It is only just to remark, however, that architects are often blamed without valid reason; for when they have succeeded in providing ample accommodation for organs of sufficient size for their churches, they are condemned by those wiseacres who have been induced to order instruments out of all proportion to the places they occupy. Cramping, crowding, and a host of other evils attend such unreasonable proceedings; and the architects get blamed for faults they have not committed. It is highly desirable that architects should study the organ sufficiently to be able to plan proper accommodation for the instruments to be placed in their churches. Even a rudimentary knowledge of the nature and construction of the organ would prevent many mistakes being made. Why architects should give the organ so little attention is a matter of surprise to many, as it certainly is a most important piece of church furniture. It is quite as necessary that the organ as that the pulpit or font should be properly placed. Apart from this, it may be made a most beautiful and effective feature in a church interior. All who neglect the organ err both on utilitarian and artistic grounds.

"The organ can go anywhere; any sort of a place will do for the organ!" are ideas which have been only too rife amongst church builders, and only too often acted upon when the slightest difficulty with regard to space has arisen, or when peculiarities of site have rendered some care and ingenuity necessary. I firmly believe some architects have looked upon organs as necessary evils—things with which they have nothing to do, except to take care that they are made as little of as possible and kept well out of sight; unfortunately, this means out of hearing also. As a general rule, an organ to be well heard must be well seen—every obstruction to sight will likewise be an obstruction to sound. It may appear strange that such a state of things should exist; but the facts must be obvious to every one who gives the subject of Church Organs the least attention. This may be said to be the age of cheap church building, and economy is the excuse for all manner of mistakes—small, low, and badly-planned organ chambers amongst the rest. The irrepressible desire to have every available yard of a church seated, to curtail every adjunct for the sake of sittings and pew-rents has, perhaps, been the most active agent at work of late years in cramping organs, and leaving organ-chambers little better than holes in the wall.

Secondly: Organ builders run in grooves. It is a matter of greater difficulty than the generality of persons have any conception of to get organ builders to depart from the lines they have been accustomed to; they, in all probability, gave their adherence to the traditional practice of the art when they swept out their masters' workshops, and ever since they have been far above being taught any *new* ideas. A short time ago, during an interesting conversation with one of the three greatest living organ builders, I asked, "How is that you organ builders leave anything to be taught you by outsiders"? He replied "We all work, day after day and year after year, in the grooves handed down to us by past generations of builders, and we thoughtlessly and conceitedly follow those grooves until we can see nothing good outside them." This admission was made by an organ builder who, of all men known to me, has displayed the least disposition and necessity to follow blindly in the footprints of others. It can only be this tendency to go on day after day in the well-beaten paths that accounts for the little progress and individuality displayed by builders of talent and reputation in the construction and appointment of their Church Organs.

This adherence to traditional grooves cannot help producing a certain degree of narrow-mindedness, and fostering a conviction that there is nothing more to be done or learnt; and it is probable, in a number of cases, that organ builders nurse their own conceit to such an extent as to look upon any attempt to convince them of errors of judgment as a gross impertinence. When an artist, in any branch of art, is satisfied that he has learnt everything, and that he has reached the highest point of excellence, he has begun his downward course. A true artist is always dissatisfied with his best endeavours, and is ever striving to achieve greater things.

In the foregoing remarks I have been alluding to the higher order of organ builders—to men who are above mere money-grubbing ideas and trade trickery, and who are working in all good faith, up to their lights.

I would rather not speak of the lower class of builders who look upon organs as merely so much merchandise, connected with which profit is the one important consideration; and who will build a Church Organ on any lines whatever so long as they make a satisfactory sum of money out of the job. These men fatten on the credulity and ignorance of the public, and secure contracts by alluring specifications, which present impressive lists of stops (generally insufficient and badly chosen) to catch the eye of ignorant organ building committees, or please the tastes of inexperienced organists. Amongst those who know very little about organ matters, there is a pretty general impression that an organ with numerous stops must be a better and more effective instrument than one with a lesser number, be they what they may. This is altogether a wrong, and, accordingly, a pernicious belief, and one which has done incalculable mischief, and, I regret to say, it continues to play into the hands of unscrupulous organ builders, to the detriment of all sound and genuine art. I do not think it is to be wondered at that builders, not overburdened with work, take advantage of this popular belief, especially while the bad practice of competitive tendering is encouraged, and inexperienced persons adjudicate and award. Human nature is human nature; and the human nature of a large class of organ builders is essentially weak.

Thirdly: The general ignorance of the public has always been an important factor in the decadence of Church Organ building. I have already said some words on this matter; but, as I feel the evil is a great and dangerous element, militating against the introduction of a more artistic era of organ building in this country, I may be pardoned for still dwelling on it.

The usual course of proceeding, when a new organ is required for a place of worship, is to appoint a small committee, with or without the organist's co-operation, with powers to invite specifications and estimates from organ builders, and ultimately to decide on the specification and tender to be carried into effect. Now, this proceeding would be satisfactory, and lead to desirable results if the members of the committee were experts, or even fairly conversant with the art of organ construction; but, in nine cases out of ten, not one of the gentlemen selected knows how the sounds of an organ are produced, nor could they, to save their lives, tell a Trumpet from a Flute pipe. This may appear a doubtful statement to some of my readers; but I can assure them it is not even an exaggerated one. With such a committee at the head of affairs, the *tradesman* has an overwhelming advantage over the *artist*; for, while the latter, in his honesty of purpose, may submit a well-considered specification, comprising a moderate number of weighty and well-balanced stops, calculated to produce the dignified and richly-coloured tones so desirable in an instrument for church use, demanding at the same time a price in just accord with the nature of the work; the former sends in a specification, which, probably, may present a list of stops half as long again as the other one, and a quotation of price considerably under that of his competitor. The committee sits upon the specifications, and, with a natural leaning, in its utter ignorance of the matter at issue, towards the longest list of stops and the cheapest price, decides without any hesitation. The member as they shake hands at parting, mutually congratulate each other on having achieved a very clever and business-like result. Alas for art! What would such wiseacres say if they were then and there assured, beyond question, that the organ they rejected, because it had fewer stops and cost more money, would be a much more effective and useful instrument, and cheaper far, in the long run, than the one they had decided on?

In all the preceding remarks I have spoken in a general way. This I desire to be clearly

understood, for there are noble exceptions in each of the classes spoken of. While writing this article a specification of a new Church Organ was sent me by a well-known organ builder; it clearly shows that by one artist, at least, the true principles of Church Organ building are being recognised. It is probable that in the course of my subsequent Notes, I may be tempted to give this specification, with my own comments on it.

Now let me turn to the special subject of the present essay. An organ, to be thoroughly useful and appropriate, from a musical point of view, should be schemed to suit, in all essentials, the place in which it is to be erected, and the work it has to do. A Church Organ, therefore, must be more or less powerful in exact proportion to the size of the building; power being understood to be volume of tone, not simply loudness and noise. The characteristic of a Church Organ should be grandeur, combined with refinement of tone; so that the instrument may be perfectly adapted for the accompaniment of choral or congregational singing, and the performance of voluntaries and other incidental pieces of a solemn and dignified character. A Church Organ is essentially an accompanimental instrument; its capabilities for the display of florid skill on the part of the organist being of secondary consideration. In Church Organs of the first magnitude, of course, there is ample scope for all classes of accompanimental and solo playing. I feel I cannot do better, in support of these views, than close the present article with a few apposite words, from the pen of an able writer, in the *Musical Standard* (June 23rd, 1877).

"In the first place, the organ should be of a size and power proportionate to the building and the congregation it will contain. We see in some churches, organs erected out of all proportion to the requirements of the service; as an instance, let that of St. Mary at Hill, London, be adduced—a very fine instrument is to be found there; but it is far too large and noisy for the comparatively small church. This instrument, although possessing great merit, is not a Church Organ in its true sense. The same fault applies to the recently-erected organ at St. Andrew's, Well-street, London; the instrument is far too large and noisy for the size of the church, placed, as it is, near the congregation. One more example, by way of contrast: take St. Alphage, London Wall; here is a small church, and an organ designed for the church—a Church Organ *par excellence*. It is unnecessary to go farther into detail upon this point: a Church Organ is an organ designed to accompany the voices, and to be at the same time capable of rendering with effect the voluntaries before and after service. When the musical demands of an ordinary Sunday service are considered, and the large proportion of accompaniment to voice-singing in which it consists, it is certain that noise is not the attribute best suited to the Church Organ, but rather the more mellow tones of the foundation stops —the diapasons, and those registers which best accompany the voice. Now, the stops of this class are much more costly than the chorus and mutation stops, and a properly-constructed organ of this type, with, say, twenty musical and well-balanced registers, would cost as much as an organ of forty stops upon the quantity principle of endless small pipes. This may be explained more clearly by stating that the last twelve notes of the 8ft. register on the keyboard cost about as much as the remaining forty-eight pipes; and hence, in the cumbrous 'churchwarden's organ,' it will be noticed how often the foundation stops are cut off at tenor C, 4ft., and grooved into a common bass, or left altogether incomplete, without any bass at all; while a number of ranks of small pipes are introduced without any proper counterbalance of the foundation tone, either upon the pedal organ or keyboards. We now see why one specification of an organ costing the same money may apparently represent a much more extensive instrument. Again, a Church Organ requires that in its design the tone of the pedal organ should be commensurate with the rest of the organ; the pedal organ ought to carry down the last octave of the keyboard an octave lower without any very apparent break in the tone. Comparatively few of our present church instruments have any pedal organ at all. A single 16ft. open wooden stop of a deep booming sound has to do duty alike for the full chorus organ and the soft choir organ vocal accompaniment. It is very rare to find a properly balanced pedal organ, even upon the most recently constructed Church Organs. The fact is, the cost of a proper pedal organ nearly equals that of the organ it has to balance upon the keyboard. Our present Church Organs are, as a rule, ill-constructed instruments; and, more or less, are erected in a commercial spirit, and form a transaction like the placing of the bricks, stones, and mortar of the building. No one takes any special interest, partly from a want of the necessary knowledge, and partly because 'it is no one's business.' What is wanted is a portion of that pure artistic spirit which animated the 'Father Schmidts' and other builders and organists of former days: men whose aim was too high for mere money-getting, and who gloried in the progress of the sublimest of all the constructive arts."

The strictures of this writer are perfectly just, and his remarks on the general deficiency of pedal organs in this country are worthy of serious attention. On this branch of my subject more will be said in the proper place.

(*To be continued.*)

FRIC'S MACHINERY FOR GRINDING CURVED SURFACES.

FIG. 1

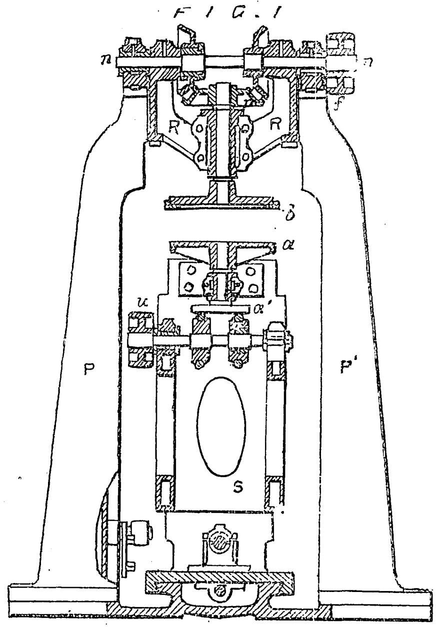

FIG. 2

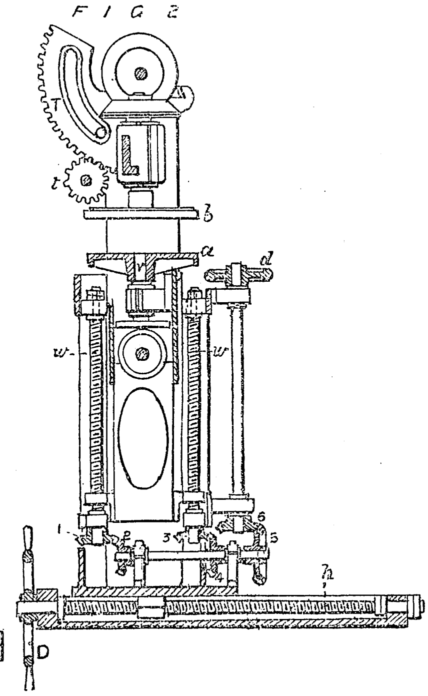

IMPROVED machinery or apparatus for grinding and polishing curved surfaces, especially applicable for forming the surfaces of lenses and glass specula, have been recently patented in this country by Messrs. Josef and Jan Fric, Vinohrady, Prague. The machines, of which several forms are shown in the drawings attached to the specifications, can be used for cutting, grinding, and polishing spherical, elliptical, parabolic, hyperbolic, and other curved surfaces; but the illustrations given herewith will convey a sufficient impression of their general character.

In carrying out their invention the patentees mount the object to be operated upon in a suitable chuck, which is rotated in the usual manner. The cutter or cutters, operating upon the object, is, or are, also caused to rotate at the same time, but not necessarily at the same speed as the chuck and the object under operation. The cutters are preferably made in the form of a disc, the cutting edges being at, or near, the outer circumference of the disc. The cutters revolve on movable axes, and such axes are so arranged as to cut the axial line of the mandrel at a certain distance, which distance is controlled by the necessary curve to be formed upon the object. The cutters are also mounted so that, while operating, they may be swung upon their centres, and thereby caused to operate upon every part of the object. One, two, or more cutters may be mounted and

FIG. 3

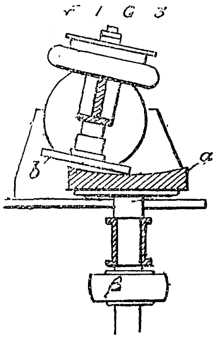

FIG. 4

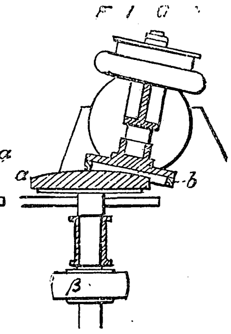


caused to operate upon the same object at the same time, in cases where several surfaces are required on the object. When both the object operated upon and the cutting tool rotate in circular paths, the surface produced will be spherical. When the cutting tool describes elliptical paths, perpendicular to the axis of the cutting tool, an elliptical surface will be formed; and, by varying the paths of the several rotating chucks and cutters, parabolic, hyperbolic, and other concave and convex surfaces may be produced. The invention is applicable to the production of exact forms in metal or glass, and especially to the cutting, grinding, and polishing of lenses and reflectors for optical purposes.

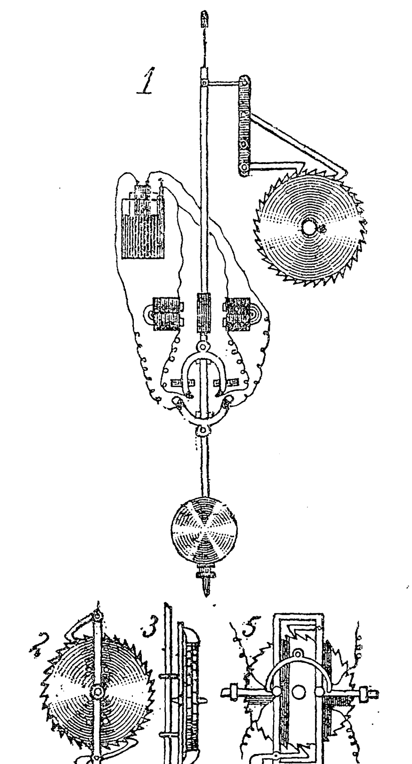
In most cases the machines are so constructed that the object to be operated upon is placed on a horizontal revolving table. It is fixed by means of pitch, or other suitable material, as usual. The cutter or polishing disc revolves on a separate axle, which may be inclined towards or in relation to the first. Both axes are intended to remain constantly in the same geometrical plane, and they must consequently meet in one point. The surface will be convex,

if the meeting point is below as shown in Fig. 4, and it will be concave if that point is above the surface, as shown in Fig. 3. The meeting point of both the axes is also the centre of the surface. The vertical axis meets the surface at its summit, which is common to all the orbits of the cutting point or the grinding circle. The summit must not lie exactly on the circumference of a circle which the cutting point describes. It may be a little inside the circle, but not outside. In the first case a grinding annular surface must act, and in the latter a central spot would remain on the surface. In finishing the ground surface, the annular surface is broad, and is composed of soft substances (of leather, lead, or pitch), while in the grinding process, the grinding rim is composed of emery, of metal, or of some other analogous substance. In many cases a common iron or wooden disc is sufficient, and it is used with a quantity of sharp quartz-sand. Messrs. Fric prefer the method of driving the axis of the cutter by means of conical or bevel friction gear, as shown in the accompanying figures. A horizontal driving-shaft *n n*, with one fixed conical wheel and one loose conical friction wheel (Figs. 1 and 2) turns, by means of the conical friction wheel *p*, the cutter *b*, at any inclination. The driving-shaft is mounted upon solid standards P and P^1. The axis of the cutter *b* is carried by the frame R R which swings on the horizontal axis *n n*, and is guided between the standards P and P^1. This frame is provided with toothed segments T, gearing with the pinions *t*. These pinions are keyed to a shaft which is carried by the standards P and P^1. In turning this shaft every inclination can be given to the grinder or cutter *b*, and it can be fixed in any position by well known means.

In addition to the variation of the inclination of the axis, horizontal and vertical movements are also required. The vertical motion is provided for by means of the table *a*. The table *a* with its support S slides between guides, and the vertical motion is produced by turning the vertical screws *w* and w^1 by means of the hand wheel *d* and the gearing 1, 2, 3, 4, 5, and 6. The whole slides horizontally on the bed-plate, and this sliding motion is produced by turning the hand wheel D and the horizontal screw *h*. In the arrangement shown in Figs. 1 and 2, the spindle of the disc *a* carries at its lower end a second disc a^1, which is supported by two small indiarubber rings fitted to pulleys, one of which is fast and the other loose; *u* is the driving pulley. This may be made to assume different positions by means of horizontal and vertical sliding motions actuated by the hand wheels *d* and D. But all these positions are necessarily confined to one and the same vertical plane. To meet this requirement the driving belt passes round two tension pulleys, which are pivoted to a bolt, sliding in a vertical slot, by which means they can be fixed to any height, as shown in Fig. 1. In some cases it is preferred to use a vertical driving belt cylinder, driving the pulley β by means of a belt, this pulley being fixed on the shaft *v* of the table *a*. It will be understood that concave surfaces are ground or cut by the outside, and the convex surfaces by the inside rim of the disc, as shown in Figs. 3 and 4, and the cutter can therefore be arranged as shown in Fig. 3, where a metal ring of angular section is fixed to the grinding disc. Its outside cylindrical face, with its lower edge, may also be used for cutting the facet of the lens or reflector. This offers the advantage that the rim or facet is centred accurately without removing the object. In case of other curved surfaces besides that of the spherical being required, each cutting point may be caused to describe an ellipse instead of a circle. All the orbits of the cutting points pass the point where the axis of the spindle of the table *a* meets the surface. The perpendicular in the centre of the ellipse on its plane must meet the axis of the spindle of the table *a* in the centre line of the rotating surface. The machine remains the same in other respects, with the exception that one or the other axis must be moved so as to obtain ellipses instead of circles, which can be obtained by known mechanical devices. The polishing of the reflector or lens is greatly facilitated by preparing the polishing disc at one operation. A negative and a positive object are readily obtained, both of which are of a nearly analogous form.

GARCIA'S ELECTRIC CLOCK.

THE clock herewith illustrated is constructed with two toothed wheels on the same shaft, one wheel having one or more teeth than the other, and both being operated by the same pawls, so that one is moved faster than the other; and by means of hands the relative positions of the wheels and the time are indicated. On the pendulum rod, Fig. 1, is an armature interposed between two electro-magnets connected by wires with one pole of a battery and with contact pieces on the ends of the shanks of a U-shaped anchor pivoted to swing on a suitable fixed support. These contact pieces are interposed between and arranged to be struck by contact plates near the free ends of an inverted anchor, also pivoted on a support, the plates being connected by wires with the other pole of the battery. In the shanks of the upper anchor are adjustable screws, which are alternately struck by the swinging pendulum rod. With this construction, when the pendulum starts to swing



to the left, it strikes the left-hand screw, and throws the corresponding contact piece on the upper anchor against the contact plate on the lower one, thereby closing the circuit through the left-hand magnet, which attracts the armature and gives the pendulum an impulse to the left, accelerating its motion slightly, until the contact piece slides off the plate and on to the non-conducting tip of the lower anchor. The circuit is thus broken and the pendulum allowed to swing by its own gravity to the right, when a similar impulse is imparted to it. The motion of the pendulum is thus maintained constant. Attached to the upper part of the pendulum is a rod secured to a lever provided with two pawls connected one above and one below its pivot. The motion of the pendulum causes the pawls to engage alternately with the teeth of both wheels, which are thereby revolved. These pawls may be arranged in different ways, as shown in Figs. 2, 4, 5, 6, and 7, Fig. 3 being an edge view of Fig. 2. The pawls act alternately, and each one always acts upon both wheels, so that when one wheel is revolved the other is revolved with it; and as one has less teeth than the other, it is evident that when the larger wheel has completed one revolution, the smaller has made one revolution and a few teeth more. The numbers of the teeth are such that the relative movements of the wheels will take place in times corresponding to the subdivisions of time into hours, minutes, and seconds. This invention has been patented by Mr. D. T. Garcia; particulars can be obtained from Mr. G. Castanos, of Guadalajara, Mexico.—*Scientific American.*

ELECTRIC WINDOW AND DOOR BURGLAR ALARM SPRINGS.

THE illustrations represent new and improved forms of burglar alarm connections for doors and windows. The door-spring (Figs. 1 and 2) consists of a hard rubber base-plate, through the

FIG. 1.

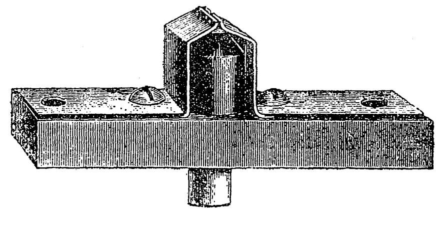


FIG. 2.

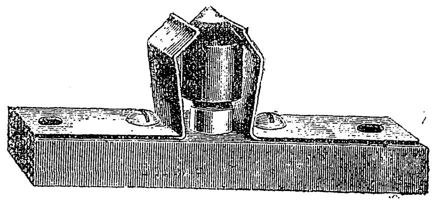
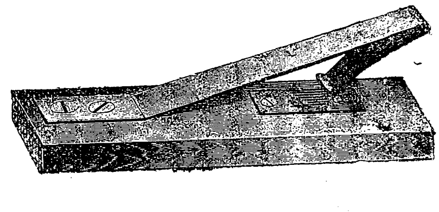


centre of which passes a stout brass rod having a rubber collar, which, with the end of the brass rod, tapers to a point at an angle of 45°. Two flat springs of German silver press on this bevel and force the brass rod out as far as the collar will allow, at the same time closing the circuit through the tip of the brass rod. When the rod is pushed back by the door, the springs are forced apart and insulated from each other by the rubber collar. By this arrangement spiral springs are unnecessary,

FIG. 3.



contact is insured by the rubbing of the surfaces, and connection is made with the wires by placing them between the spring and door-frame at each end of the plate. The window-spring requires no mortise beyond a countersinking of one-eighth of an inch, and, on account of its peculiar shape, makes a rubbing contact with a screw or plate placed under the free end. The inventor and manufacturer is Mr. Frank A. Perrett, of Brooklyn. —*Electrical Review* (N.Y.)

HOME-MADE WINES AND DRINKS.

THE flower and berries of the elder (*Sambucus*) have been made use of for wine-making from very early periods. The best known of the elder species is the common black elder (*Sambucus nigra*), which is a native of this country, and very generally diffused. It is a small tree, or, rather, bush, with an irregularly but oppositely branched stem, and it grows with the greatest rapidity. The cream-coloured flowers have a sweet, but rather heavy, smell; the fruit is a globular, purplish-black berry, with a red stalk. The variety mostly cultivated for wine making is the one above mentioned; but the berries of the green and yellow are also applicable to the purpose. The elder requires a good soil, a moist situation, and free exposure to light and air.

Elderflower Wine is made from the flowers in this manner:—(1) Gather the flowers on a dry day; remove all stalks, and to every quart of flowers allow one gallon of water, and 3lb. of loaf-

sugar; boil the sugar and water for a quarter of an hour, then pour it on the flowers, and let it work for three days; then strain the wine carefully through a hair sieve, and put it into a cask. To every five gallons of wine add ½oz. of isinglass, dissolved in cider, and three eggs (whites only) beaten up; close up the cask, and stand six months before bottling off. (2) Boil 18lb. of powdered loaf-sugar in six gallons of spring water; beat up the whites of two eggs, and add; skim very thoroughly, and put in a quarter of a peck of elder flowers, picked from their stems; take off the fire, and stir until cold, then add four tablespoonfuls of yeast and six spoonfuls of lemon juice, strained and free from pips; mix well with the liquor by stirring twice daily for four days. Stone 6lb. of Malaga raisins, and put them into a well cleaned-out cask; pour the wine upon them. Stop up the cask closely, and keep it in a rather warm place. If made in July or August, bottle off in February or March. This wine, when well-made, very much resembles Frontignac.

Elder-flower Vinegar.—To every half-peck of the flowers, free from stalks, put a gallon of strong ale vinegar; set in the sun in a stone jar for a fortnight, then filter through a flannel bag; bottle off into quite small bottles.

Elderberry Wine.—(1) Gather the berries when quite ripe, on a dry day; pick them off the stems, and bruise them with your hands. Strain the juice; let the liquor rest in glazed earthenware pans for twelve hours to settle. Allow to every pint of juice a pint and a half of water, and to every gallon of the mixed water and juice 3lb. of good moist sugar. Put it over the fire in a large saucepan, and when it is ready to boil, clarify it with the whites of four eggs. Let it boil for an hour, and when nearly cold, put in some yeast to work it; pour it into the cask, reserving some of the liquor to fill up the cask with, as it sinks with working. If you have about ten gallons or so, it should be fit to bottle off in two months' time after it has been closed down. Keep at least a year in bottle. (2) Gather the berries when quite ripe, and in dry weather. Pick them clean; put them into a copper with half a gallon of water, and keep up a slow fire until the berries sink; then strain the juice through a hair sieve, and to every gallon of it allow three gallons of soft water, and to every gallon of the mixed liquor 3lb. of good moist sugar. Put back into the copper, and boil for an hour, skimming thoroughly; draw off into a tube, and when it is about 70°, put a toast spread with yeast into it, and let it work for forty-eight hours, or longer, if necessary; pour it or draw it off, if you have a tap in your tub, as should be the case, into the cask which is to hold it, and if you have eighteen gallons of liquor, add 1oz. of cloves, 2oz. of allspice, 2oz. of Jamaica ginger, and 1oz. of sweet almonds, all bruised. Bung very slightly until fermentation is quite over; then close down tightly, and tap in three months.

(3) Old recipe:—Put the ripe picked-over berries into an earthen pot; put this into a copper with sufficient water to come up about two-thirds of the height of the pot, which is about as far as the berries should reach inside; be careful that no water touches them. Make a gentle fire, and keep the pot in the water till it is quite hot; then take it out. Pour the berries into a coarse cloth, strain the juice, and put it into a large saucepan; to every quart of juice allow 1lb. of good moist sugar; let it boil, and skim well. It should boil until rather thick, then pour it into a jar. Put 60lb. of raisins into a cask, and fill it up with water; let it stand for a fortnight; stir it well every day; then pour off the liquor into a clean cask that just holds it. It should stand until it has done hissing; then bung it down close, and stand until fine. To every gallon of this liquor allow half a pint of the elder syrup; mix well, and when it has fined down, rack off into another cask; bottle off after three months.

(4) Chop a quantity of Malaga raisins quite fine; allow a quart of water to every pound of raisins, and put raisins and water into an open tub; cover over with a double cloth, and let it stand for nine days, stirring up each day. Then draw off the liquor as long as it will run, and press the raisins to get out the remainder of the juice; mix all together in a barrel. To every gallon of liquor allow a pint of the juice of elderberries, prepared simply by mashing the berries with the hands, and straining off the juice. Stop down close, and stand for six weeks, then draw off the fine liquor, and to every gallon add ½lb. of moist sugar. Stand again until quite fine, and then bottle off. Keep in a cool cellar for use.

(5) Take 30lb. of Malaga raisins, add eight gallons of water to them, and allow to steep for twelve days; draw off the liquor, and put it into a copper with two gallons of elderberry juice; boil for ten minutes, removing all scum as it rises; then add 7lb. of moist sugar, ½oz. of allspice, ½oz. of cloves, and 2oz. of Jamaica ginger, all well bruised; boil again for an hour, skimming thoroughly; draw it off, and float some toast covered with yeast in it; leave it to work for two or three days, then pour it into a clean cask, and when all fermentation is over, bung down tightly. If made the end of August or in September, this wine would be ready to tap about Christmas, and should be bottled in January or March.

(6) Allow three quarts of elderberries, which are quite ripe and carefully picked over, to every gallon of water; boil, skimming well, until the berries break, then strain the liquor, and to every gallon allow 3lb. of moist sugar, and to every four gallons add 2oz. of bruised ginger, 2oz. of cloves, and 2oz. allspice; boil for an hour; work with yeast when nearly cold; cask it the third day, and when all working is over, bung down.

(7) To every gallon of berries allow a gallon of water; steep in a tub for four days, bruising well each day. Squeeze the pulp, and strain off the juice. To every gallon add 3lb. of brown sugar, and spices in the same proportion as in the above recipe; tie the spice in a muslin bag; boil all the ingredients for an hour; work with yeast when nearly cold; then pour into a well-cleaned cask, and bung down when the fermenting operation has quite ceased. Bottle off in two or three months. Into every bottle put a lump of white sugar and a little brandy.

(8) To one gallon of berries add three quarts of water; bruise in a tub, and stand for three days. To every quart of liquor allow 1lb. of moist sugar, 1oz. of ginger, and 1oz. of cloves, both bruised (the spice should be put into muslin bags); put all together into a perfectly clean vessel, and boil for one hour; then pour into an earthenware pan; when cool enough to dip in the finger, put in a tablespoonful of brewers' yeast; let it work three days, then skim and put into a small cask just large enough to hold the amount. Keep out the air for three weeks, but do not bung down close until that period has elapsed. Tap in two months to test it; if fine, bottle off.

I have given a variety of recipes for making this wine, as it is a very favourite beverage, more especially in country places. A glass of well-made elderberry wine taken hot at bedtime in the cold weather is by no means to be despised, and a drink I have frequently been called on to taste in farmhouses about Christmas time. In Cornwall it is quite a custom for farmers' wives to offer any visitor who happens to drop in a slice of what is there termed yellow (meaning saffron) cake and a glass of home-made wine, usually elderberry, and very well made it generally is.

Elder Beer Made with Ginger.—Take a bushel of clean-picked ripe elderberries; put them into a barrel of strong wort; boil up the liquor in a copper for a few minutes, then strain it off, and when cold, return it to the barrel, and work it in that, not in an open tub; add 1lb. of whole ginger, and stand for ten months in the barrel, well bunged down, before using it.

Mead is an old-fashioned beverage, but a very pleasant one, if care is taken in making it. It is generally made over-strong—too much honey being used to the proportion of water. The following is a good recipe:—(1) On 30lb. of honey (clarified) pour thirteen gallons of soft water, boiling hot. Clarify with the whites of eggs, well beaten; boil again, remove all scum as it rises, add 1oz. of best hops, and boil for ten minutes, then pour the liquor into a tub to cool, spreading a slice of toast on both sides with yeast, and putting it into the tub when the liquor is nearly cold. The tub should stand in a warm room. When fermentation has thoroughly begun, pour the mixture into a cask, and, as it works off, fill up the cask, keeping back some of the liquor for this purpose. Bung down closely when fermentation has ceased, leaving a peg-hole, which can be closed up in a few days. Let it remain a year in the cask before bottling off.

(2) To 15lb. of honey add six gallons of water; clarify the honey with white of eggs; boil for ten minutes, and keep thoroughly skimmed; add a handful of mixed herbs, thyme, rosemary tops, and bay leaves; boil for half an hour more; strain the mixture into a tub upon five pints of ground malt; stir well together, and when lukewarm, strain through a cloth into another tub; work it with yeast, and, when fermentation is set up, pour it into a cask. Suspend in the cask a muslin bag containing sliced ginger ½oz., ¼oz. each of cloves, nutmeg, and mace, well bruised; bung up tightly when it has ceased working, letting the bag of spices remain. It should stand in the wood for a year, and then be bottled off.

Sack Mead.—To every gallon of water allow 4lb. of honey; boil for three-quarters of an hour, skimming well; to each gallon of liquor add ½oz. of hops; boil again for a quarter of an hour; pour it into a tub, and let stand for twenty-four hours, working with yeast; then pour into the cask, and to thirteen gallons of liquor allow a quart of sack. Close lightly until all fermentation has ceased, then bung up close. If a large cask, allow a year in work before bottling off.

American Mead is made with cider. Take 20lb. of honey and twelve gallons of good cider, and blend them together in a tub; ferment with yeast, then pour into a cask, and add half a gallon of rum, half a gallon of French brandy, 4oz. of red tartar, dissolved, and ½oz. of cloves. Bung down close when it has ceased working, and bottle off at the end of three months; it will be fit for use thre months afterwards.

A wine called *Saragossa* is made with honey. To every gallon of water used add a handful of fennel root and two sprigs of rue; boil carefully for half an hour, and then strain through a hair sieve; add to each gallon of this liquor 3lb. of well-clarified honey; boil for two hours after the addition of the honey, skimming frequently; when the liquor is quite cold, pour it into a clean cask, keeping it for twelve months before bottling off, and six or eight months in bottle before use.

A very useful and economical wine for culinary purposes can be made with honey and cider in the following manner:—Take some new cider from the press, and mix it with as much clarified honey as will support an egg; boil it in an enamelled saucepan for half an hour, skimming it well all the time; when entirely cool, pour it into a cask, but do not quite fill it; bung down close when all fermentation is over, and keep in the cask six or eight months before bottling off, after which it will be fit to drink in two months. This is a rich, strong wine, keeps well, and answers admirably for cooking purposes instead of white wine.

Balm Wine.—(1) Into eight gallons of water put 20lb. of moist sugar; boil for two hours, skimming thoroughly; then pour into a tub to cool; place 2½lb. of balm tops, bruised, into a barrel with a little new yeast; when the liquor is cold, pour it on the balm; stir it well together, and let it stand twenty-four hours, stirring it frequently; then close it up tightly at first, and more securely after fermentation has quite ceased; when it has stood two months, bottle off, putting a lump of sugar into each bottle; cork down well, and keep in bottle at least a year.

(2) Put a peck of balm leaves into an open tub; pour on them four gallons of boiling water; cover up the tub, and let them infuse for twelve or fourteen hours; strain the liquor at the end of that time through a hair sieve, and to every gallon add 2lb. of good moist sugar, stirring well for twenty minutes; take the whites of four eggs, whisk them over the fire in a saucepan; remove it from the fire as the scum rises, and skim the latter off; then add it to the liquor; boil the whole for three-quarters of an hour, letting it work three or four days before you tun it; bung down, and, when fine, bottle it off; in six or eight months it will be fit to drink.

The fruit of the bilberry or bleaberry (*Vaccinium myrtillus*), in places where it grows plentifully, is often made into wine. It grows chiefly on moors and in waste places, and is a small shrub about a foot or so in height. In Great Britain it is found mostly in the northern counties and in the hilly districts of the southern counties. Its flowers appear in May, and its fruit ripens in autumn. Two other species of *Vaccinium*, the red (the cranberry) and the black (the whortleberry), are also common in many parts of this country, and are used, as are bilberries, for tarts, preserves, and jellies.

Bilberry Wine.—The fruit should be picked on a very dry day, when it is quite ripe. The leaves and stalks must be carefully removed from the berries, and the fruit then weighed. To four gallons of fruit allow either six gallons of cold water, or else three gallons of water and three of cider, and 10lb. of good moist sugar; let all these ingredients ferment in an open tub until working is over; then add half a gallon of brandy, a handful of lavender and rosemary leaves mixed, 2oz. of powdered ginger, and 2oz. of powdered tartar; let the liquor rest after this addition for forty-eight hours, then strain very carefully through a hair sieve into a perfectly clean cask, laying the bung lightly on the bung-hole until the working is quite over, and no hissing sound is heard; then close down quite tightly, and bottle off at the end of three months; keep six or eight months in bottle before use.

Cranberries can be made into wine in the same way. In America the cranberry is largely cultivated, and forms a considerable article of commerce, a quantity of the fruit being exported. In the northern parts of Russia it is also very abundant.

Ratafia, for flavouring, is by no means difficult to make when the peach is in season. The following is a simple recipe:—Blanch 2oz. of peach or apricot kernels; bruise them well; put them into a bottle, and fill it nearly up with good brandy; dissolve in a cup of cold water ½lb. of white sugar-candy, and add it to the brandy after it has stood for a month on the kernels; strain off the kernels before you add the sugar; then filter through paper, and bottle off in small bottles for use. Another rather more expensive method of making it is to take fifty bruised peach kernels, ¼lb. of bitter almonds, 1lb. of white sugar-candy, and mix thoroughly with one and a half pints of rectified spirits of wine; then add three quarts of water and one and a half gallon of malt spirits.—*Confectioners' Journal.*

SCIENTIFIC SOCIETIES.

ROYAL MICROSCOPICAL SOCIETY.

THE second meeting of the session was held on the 10th ult., at King's College, Strand, W.C., the president, Dr. Dallinger, F.R.S., in the chair.

Mr. Crisp said that probably the Fellows would remember that some time ago they received a microscope from the executors of the late Miss Tucker. It had been since discovered that the comparatively inferior instrument then received was not the one bequeathed to the Society, but the much larger and more valuable microscope which, together with a box of apparatus and a cabinet of objects, was on the table, and was likely to be very useful to the Society.

The President thought that such a donation should be the subject of a formal acknowledgment, and therefore put to the meeting a motion for giving the thanks of the Society to the executors for forwarding the instrument.

Mr. T. C. White exhibited an album of photomicrographs of a great variety of objects, including also some photographs of the apparatus employed, which was very simple. It was so contrived as to be used either as a projection-microscope or a camera.

Mr. Crisp, referring to the interest which still attached to the work done by Leeuwenhoek with his microscopes, exhibited two facsimiles of those instruments. A collection of them was formerly in the possession of the Royal Society, but has disappeared—probably thrown away by someone unfamiliar with their form. The drawings gave only a very poor idea of what the original instruments were like, and it had been with much interest that some of the Fellows had had an opportunity of inspecting one, which was brought to England during the recess by Prof. A. W. Hubrecht, an eminent Dutch zoologist, who to other accomplishments added that of a most extraordinary mastery over the English language, both as regards grammar and pronunciation. Copies of the microscope had been made by Mr. Mayall, which were so close a resemblance to the original that only by minute examination was it possible to say which was which.

Mr. Crisp also exhibited Golfarelli's micrometric microscope for the special use of watchmakers in examining the teeth of very fine escapement wheels, and commented on the wide field that was opening if special microscopes were to be made for the different purposes to which a microscope could be put. He also exhibited Cailletet's apparatus for examining the effects produced upon minute aquatic organisms by enormous pressures up to 650 atmospheres, necessitating great strength in the apparatus. He also called attention to two "telescopic" objectives (belonging to Prof. Abbe) so arranged that the image of the object was not altered in size by varying the length of the draw-tube, a matter of importance in the case of micrometric measurements.

Mr. J. Mayall, jun., called the special attention of the meeting to the exhibit of Messrs. Powell and Lealand, who, not wishing to be behindhand in the matter of objectives, had procured some of the new kinds of optical glass from Jena, and had worked out an apochromatic 1-12th homogeneous-immersion objective on their own formula. They had produced an objective which certainly compared favourably with those of Zeiss, which had been exhibited in this country. The Fellows could see for themselves how extremely well this objective stood the test applied to it, using both axial and oblique illumination. It should be remarked that the eyepiece used by Mr. Powell had a magnifying power of 40 diameters *per se*, and even under this severe test the new objective did not break down. This eyepiece, it should be remembered, was a much higher power than the highest in the Zeiss series, which gave 27 only. He believed Mr. Powell's eyepieces were made on a formula analogous to that of Zeiss, though not quite the same. The formula of Mr. Powell's new objective was evidently less complex than that of Zeiss's; there were fewer lenses in the combination, and hence the difficulties of the construction were reduced. Mr. Powell also provided a correction-adjustment, without which it was impossible, in his opinion, to obtain the best definition with every kind of object and under every variety of illumination. The meeting would, he was sure, be gratified to know that directly the new optical glass was available opticians in this country had put their shoulders to the wheel, and had at once produced the first-class objective which was now exhibited.

The President said he had had the opportunity that evening of examining this new lens of Mr. Powell's, and he could only say that he was quite astonished at the definition which it gave. Even under the highest-power eyepiece it gave almost, if not quite, as perfect an image as those produced with the lower eyepieces. Since the date of their last meeting he had been afforded the opportunity of examining very carefully a set of the new lenses made by Zeiss, together with a new and complete set of eyepieces, and, whilst he was perfectly convinced of the immense gain which objectives of that construction would be to the microscopist, he was also perfectly sure that serious errors would be introduced unless they were made by the best makers. It would be interesting to know that Mr. Mayall had also made a critical examination of these lenses quite independently, and had written down the results, and that when these were afterwards compared with the observations he had himself recorded, the two sets of results were found to be almost exactly coincident. It was also a matter for great satisfaction that Mr. Powell had added to the value of his objective still further by increasing the power of his eyepieces with such excellent results. Except in one single instance, he had never seen the test objects shown better.

Mr. Cheshire thought Mr. Powell was greatly to be congratulated upon the success which he had attained, as the definition of the objects exhibited by him under such a high power was magnificent. It was, however, extremely difficult to compare the one with the other at a distance, and he suggested that a committee might be appointed to make comparisons under favourable conditions.

Mr. Crisp said, that if Fellows wanted to see the two objectives on the same evening, they would be able to do so at the conversazione on the 24th inst.; but he was afraid the suggestion of Mr. Cheshire could not be acted upon. Something of the kind had been done on a former occasion, and it was found to produce more harm than good.

Mr. Watson exhibited a new form of Histological microscope, which had been designed with the idea of producing an instrument as strong as possible at a moderate cost. It had a lever fine-adjustment; but the principal feature of novelty about it was two raised ridges on the stage to carry the slide, which was thus prevented from scratching the surface of the brasswork, and in consequence of the reduced size of the points of contact could be moved about with much less than the usual amount of friction.

The President said this little improvement was so simple and effective that it would no doubt commend itself to all who saw it.

Mr. C. Beck explained the additions which had been made to the portable National microscope, one of which be exhibited.

Mr. F. O. Ridley read a paper "On the Classification and Spiculation of the Monaxonid Sponges of the *Challenger* Expedition," illustrating his description of the various typical forms by drawings on the blackboard.

Mr. A. Dendy also read a paper "On the Anatomy and Histology of the Monaxonid Sponges of the *Challenger* Expedition," the subject being illustrated by drawings and specimens.

The President said the details concerning this group of sponges which had been given in the two papers before them were certainly very full and valuable, and he very much regretted that owing to the lateness of the hour it was impossible to afford time for their discussion. The authors, however, were to be much congratulated on the lucidity of their explanations that evening.

Dr. E. M. Crookshank read a paper on "Flagellated Protozoa in the Blood of Diseased and apparently Healthy Animals," illustrated by drawings, photographs, and specimens. He described a disease known in India as surra, occurring among horses, mules, and camels. A parasite was discovered in the blood of these by Dr. Evans, and was referred to Dr. T. Lewis for an opinion as to its nature, who concluded that it was not identical but closely allied to the flagellated organisms which he had observed in Indian rats. Five years later an outbreak of the same disease occurred in British Burmah, and the report of an investigation was published by Veterinary Surgeon Steel. Steel observed the same parasite, but regarded it as closely allied to the spirillum of relapsing fever in man, and named it *Spirochæta Evansi*. This opinion was not accepted by Dr. Evans, who placed blood-stained preparations and material for section cutting in Dr. Crookshank's hands for further opinion. Dr. Crookshank at once dispelled the idea of the parasite being a spirillum, and gave a full account of his observations. These had led him to discover an *anterior* flagellum, a longitudinally attached undulating membrane, and a posterior acutely pointed rigid filament, from which characters he recognised that the parasite was a flagellated monad, probably absolutely identical with the parasite discovered by Mitrophanow in the blood of the carp, and named by him *Hæmatomonas carassii*. Dr. Crookshank consequently observed that the Surra parasite should rather be called *Hæmatomonas Evansi* than *Spirochæta*, as suggested by Steel. Lewis's observation with regard to the flagellated organisms in Indian rats, led Dr. Crookshank to investigate the species obtainable in England, which resulted in his discovering flagellated parasites in 25 per cent. of apparently healthy rats from the London sewers. These organisms proved to be morphologically identical with the surra parasite and the parasite described by Mitrophanow in the blood of the carp, and were also recognised by a photomicrograph made by Lewis to be identical with the organism observed by him in Indian rats, though Lewis's description and figures presented material differences.

The President regretted that time did not permit of a proper discussion of the subject, which was evidently of great interest and practical importance, and Prof. Bell referred to some of Bütschli's papers.

Dr. Crookshank said it was rather a disadvantage to discuss the subject of a paper, only parts of which had been read; but when the paper was before them in extenso, they would see that he had not overlooked what Bütschli had said. At that late hour of the evening (10.10 p.m.) it was not possible to pursue the matter further.

SCIENTIFIC NEWS.

THE comet discovered by Barnard on Oct. 5 is visible to the naked eye, as it rises between 4 and 5 a.m. Dr. Oppenheim's ephemeris for the ensuing week at Berlin midnight reads—

	R.A.			N. Dec.	
Dec. 5.	16h.	0m.	54s.	17°	51·8′
7.	16	23	24	17	33·0
9.	16	45	27	17	0·1

Brightness still increasing.

Herr August Wagner, chief assistant (vice-director) of the Pulkowa Observatory, under Prof. Otto Struve, died on Nov. 14, at the age of fifty-eight.

General J. T. Boileau, F.R.A.S., F.R.S., who died recently at the age of 81, had charge of Simla Observatory many years ago, was elected a Fellow of the Royal Astronomical Society in 1840, and of the Royal Society some time before. Of late years he devoted much of his time to the establishment of institutions for the daughters of officers and soldiers of the army, and we regret to hear that members of his own family are left in rather straitened circumstances. An influential committee has been formed to raise a fund for the purchase of annuities, Lord Napier, of Magdala, being the chairman, and Major-General P. Ravenhill the hon. sec.

A fund is being raised, too, to purchase an annuity for the daughter of the late C. W. Peach, the famous naturalist and scientific observer, who died last March. Hugh Miller, Sir H. de la Beche, Sir Philip Egerton, Darwin, Huxley, Carpenter, Ray Lankester, not to mention others, have all been indebted to the labours of Peach for valuable information, and his important collection of fossils from Sutherland is now in the British Museum. Amongst the members of the committee are Sir W. Turner, Sir J. D. Hooker, the Director-General of the Geological Survey, Prof. Tait, Prof. E. Ray Lankester, John Murray, and W. Pengelly.

The Royal Society have just received from Egypt a consignment of specimens of the different strata of soil in the Delta. The borings have been carried out to a depth of nearly 200ft. and the solid bottom has not yet been reached. The Royal Engineers in Egypt have been intrusted with the work. The specimens, which are chiefly of sand and clay strata, are deemed of great importance, and the Society has granted money for the continuance of the work, which will be carried out by the detachment of Engineers as hitherto.

For one of the Rosebery lectures before the Edinburgh University Mr. G. J. Romanes chose "Aristotle as a Naturalist." In thought and language, in mode of conceiving and grappling with problems, and in the general reasoning which he employed, Aristotle resembled much more closely than any other philosopher of antiquity the scientific investigator of the present day. Mr. Romanes said that close upon 500 species of animals had come under his observation, including 70 species of mammals, 150 of birds, 20 of reptiles, and 116 of fish, and Aristotle would have differed from the natural scientist of modern times in one important particular. He everywhere regarded the purposes of nature as operating under limitations imposed by what he called absolute necessity. Monsters, for example, he said, were not the intentional work of nature herself, but the victory of matter over nature. He divided

nature into two classifications—organic and inorganic. Man he placed at the head of the animal kingdom, and he drew the true psychological distinction between him and the lower animals—namely, that animals only know particular truths, and never generalise from abstract ideas. His conception of life was more in accordance with that of modern science than any conception formed of it either in ancient times or in the middle ages. Aristotle was the first philosopher who distinctly affirmed the importance of heredity as a principle, not only in natural history, but also in psychology. He would have been something more than human if either his observations or his reasoning could everywhere have been justly compared with those of scientific genius more favourably circumstanced; but it was the glory of Aristotle that both his observations and his reasonings could stand such a comparison so astonishingly well as they did. When we remember the enormous range of his work in biology, that he was born into a world of mysticism, nurtured in the school of Plato, and therefore himself compelled to forge the intellectual instruments of research, there could be no question that Aristotle stood forth, not only as the greatest figure of antiquity, but as the greatest intellect that had ever appeared on the face of the earth.

At a recent meeting of the Bath Microscopical Society, Mr. Philip Braham, F.C.S., read a paper on "Films," in which he said that all optical instruments and even the act of seeing depended on films; were it not for the constantly renewed film of moisture over the surface of the eye vision would be impossible. The use of films in lenses was demonstrated by rendering a pair of translucent plates perfectly transparent by a film of liquid, of the same refractive power as the plates, placed between them. The use of Canada Balsam in cementing lenses together and rendering the combination achromatic was explained. In exhibiting some experiments with soap-films under the microscope, Mr. Braham explained that the thickness of the films when the colours appear is between the 36,000th and the 62,000th of an inch—the extreme wave-length of light; but where grey patches are seen the air on each side of the film is in optical contact, so that no light is reflected from the film, the thickness being under the two-millionth of an inch, and as this film is composed of several molecules which must be coherent, and cannot consist of less than three, but probably more, we could safely infer the size of the molecules to be very much less than the six-millionth part of an inch, so that by actual experiment and calculation we could estimate the size of the molecules. The films that inclose the liquid matter in the vitreous humour of the eye and prevent convection and other currents in that body, were shown to be so thin that no interference took place.

In a paper read before the Society of Arts last week on the "Purification of Water by Agitation with Iron and by Sand Filtration," by W. Anderson, M.Inst.C.E., the rather extraordinary assertion was made that "It is well-known that iron is inimical to vegetable and animal life. The presence of salts of iron in the soil produces sterility." In a number of analyses of various soils, which lie before us as we write, those marked sterile contain little, if any, iron, while those which are said to be fertile have considerable percentages of iron.

The directors' report of the Blackpool Electric Tramway for the year ending October 31st, shows that the undertaking is a commercial success, the profit allowing of a dividend of 5 per cent., and a considerable contribution to the depreciation and reserve fund.

The Metropolitan Board of Works have given notification of their intention to apply for a Bill enabling them to provide a new means of communication across the Thames at Blackwall, consisting of a tunnel under the river. The proposed subway will consist of a single tunnel or two parallel tunnels, and will be for the use of carriages, carts, and other vehicles, as well as foot passengers.

At the meeting of the National Academy of Sciences, Boston, Mass., Prof. E. C. Pickering, of Harvard Observatory, read a paper on the "Draper Memorial Photographs." This work of stellar photography was begun with the aid of the National Academy, which appropriated a portion of the Bates Fund to the work, but it becoming too extensive, the widow of Prof. Henry Draper has continued it as a memorial of her husband. The work is of three classes: 1. The general stellar spectra; each star with a photographic exposure of five minutes, a work which includes from 6,000 to 7,000 spectra; 2, a series of exposures of one hour each; and 3, investigations with the aid of Prof. Draper's 11in. reflecting telescope, which has been lent to Prof. Pickering for this work. The mounting of this large mirror, with its attendant prism, was described, and the progress of the work indicated. The paper was illustrated with lantern projections. The work with the new instrument is only just begun, photographs having been taken for two or three evenings. There is now no lack of light, but the greatest difficulty is to secure sufficient dispersion of the spectra. There are two classes of stars with distinct spectra. The first class has numerous bright lines on faint continuous spectra; in the second class, which includes more of the variable stars, the lines are much fainter. Prof. Young stated that progress during the year had been so marked as to lead to the hope that the study of the approach and recession of stars could soon be studied with satisfactory results.

At a recent meeting of the Academy of Sciences, Paris, M. Stroumbo drew attention to an interesting mode of recomposing white light by the aid of the colours of the spectrum. The prism is mounted upon an axle parallel to its edges, so that it may receive rapid rotatory movement. The seven prismatic rays are thrown on a pure white screen, the prism is then revolved, and when rotation becomes rapid the colours disappear, and a band of white light results.

M. Debray has reported to the Academy on behalf of the chemical section in reference to the alleged isolation of fluorine by M. Moissan. That chemist condenses pure anhydrous hydrofluoric acid in a U-shaped platinum tube, closed by two stoppers of fluor-spar, through which platinum wires pass. The lower part of the tube is plunged into chloride of methyl caused to evaporate rapidly by the passage of a current of air, whereby a temperature of — 50° C. may be secured. When a current from 20 Bunsen elements is passed through the hydrofluoric acid, there is a regular disengagement of hydrogen at the negative pole, while a gas of strange properties is evolved at the positive pole. This new body decomposes water in the cold, with disengagement of ozone; phosphorus burns in it, with production of fluoride of phosphorus; and crystallised silicon takes fire in it, with formation of fluoride of silicon. It is open to conjecture that the gas may be either free fluorine, or perfluoride of hydrogen, or a mixture of hydrofluoric acid and ozone. But M. Moissan discusses these hypotheses, and concludes with much plausibility that the new gas is really the long-sought-for element — free fluorine. If he is right, his researches are among the most interesting investigations in modern chemistry.

Drs. Tizzoni and Cattani, of Bologna, have been making a study of cholera during the present year, and they confirm and extend Koch's conclusions. They consider that flies play an important part in the propagation and dissemination of the disease; but their investigations confirm the assertion that the bacilli cannot live in an acid medium such as the healthy gastric secretion.

THE *Moniteur Industrielle* states that a mixture of oil and graphite will effectually prevent screws becoming fixed, and will protect them for years against rust. The mixture facilitates tightening up, is an excellent lubricant, and reduces the friction of the screw in its nut. Why not use clean fat with the graphite or blacklead? Washed hog's lard is the best thing.

PHILADELPHIA will soon have the highest tower "in creation." The town-hall of that city, which is nearing completion, will have a tower 537ft. high, consequently 17ft. higher than that of Cologne Cathedral. Until the erection of Eiffel's Tower at Paris, Philadelphia will possess the highest building. The tower is to be surmounted by a bronze statue (36ft. high) of William Penn. The new town-hall, the foundation stone of which was laid in 1872, will cost the city the enormous sum of twenty milllion dollars.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents. The editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the EDITOR *of he* ENGLISH MECHANIC, *332, Strand, W.C.*

All Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks, a vice from whence great inconveniences derive their original."—*Montaigne's Essays.*

THE LATITUDE OF THE LICK OBSERVATORY—THE STELLAR PHOTOGRAPHS OF MM. HENRY FRERES —ONE OF THOSE "COMMUNICATIONS" THAT CORRUPT GOOD MANNERS—DEATH OF THE "ASTRONOMICAL REGISTER"—U CYGNI—THE CITY AND GUILDS OF LONDON CENTRAL INSTITUTE—IS JUPITER SELF-LUMINOUS? — LANDSCAPE-PAINTING IN OIL COLOURS—SINGLE LENS EYEPIECE.

[26544.]—I LEARN that, during the month of August last, a fresh determination was made of the latitude of the Lick Observatory on Mount Hamilton, U. S., with the Repsold meridian circle installed there; the mean of the results of all the observations coming out as 37° 20′ 24·9″ N., which is therefore provisionally adopted as the latitude of the centre of the mercury basin beneath the circle. I fancy that this is slightly less than that derived from previous observations. Be this, though, as it may, it is difficult to avoid envying Professor Holden as the possessor of the matchless Lick achromatic, 4,250ft. above the sea level, with the mists and atmospheric worries of all sorts with which we are afflicted far beneath his feet; with our at present practically invisible Mercury and Venus nearly 32° and some 30½° respectively above his horizon; with Saturn at an altitude of upwards of 74° when on the meridian, and with Neptune under the same conditions at one of over 70°. If ever anything fresh is to be learned as to the physical structure of the last-named planet, surely it is to Mount Hamilton that we must look for the information.

Through the kindness of an old friend, I have had an opportunity of studying at my leisure a few of the perfectly marvellous stellar photographs of the MM. Henry Frères, of Paris; and among them one from a facsimile of which the very remarkable caricature on p. 65 was presumably taken. Granting the difficulty of reproduction, I must say that your engraver has failed conspicuously in giving an idea of this wonderful autotype of the glorious region in Perseus delineated in the original. This particular photograph gives the stars black upon white, like your woodcut; but in the case of other charts of regions in Gemini and Cygnus, they appear as they do in the sky—white upon a black ground. The circularity of the discs is very remarkable, and shows to what perfection the MM. Henry have brought their process. Everyone familiar with the working of the clock applied to an ordinary equatoreal knows that, although, all things considered, it goes with wonderful steadiness, yet that it will not keep a star rigidly on the intersection of two lines in the eyepiece for any length of time without repeated attention. Now, the exposure of the original plates of some of these astonishing photographs must have been a matter almost of *hours*, and under ordinary circumstances the images of the stars would inevitably have been distorted into ellipses and all sorts of figures. As a matter of fact, they are, as I have said, most beautifully circular, and as permanent records of the aspect of those regions of the sky which they represent, are, so far, as unsurpassed as they seem unsurpassable. For purposes of comparison, however, hereafter, photographs alone must be employed, as the magnitudes are actinic, and not visual ones. It is very notable that by sufficient exposure multitudes of stars imprint their images on the sensitive plate, of which no trace is under any circumstances perceptible by the human eye employing the same telescope.

Being in London one day, not long ago, I got sight of a little book by Mr. G. Pinnington, in which he shows (to his own satisfaction) that Kepler's third law is all wrong; that Newton "cooked" his calculations to bring observed facts

into accordance with this law as it stands; and in fine, that our present data of the elements of the solar system are all adrift, and that the earth, instead of being, as astronomers weakly suppose, 92,359,300 miles from the sun, is really removed from him by an interval of 115,658,780 miles! Now, if any of my brother readers wonder why I notice this at all, I will say at once, because the title-page of the pamphlet commences thus: "A paper communicated to the Royal Astronomical Society, January 13th, 1885," which certainly would induce anyone ignorant of the facts of the case to imagine that the Society had in some way *accepted* Mr. Pinnington's paper. Let me hasten to assure anyone labouring under such a delusion that the Fellows of the Society have never heard one syllable about Mr. P. or his production either. I protest against the assumption that a man has a right to pen any rubbish he pleases, put a penny stamp on to it, address it to a learned society, and then to announce publicly that it was "communicated to" that society on a specified day.

It is with sincere regret that I learn from an announcement on the cover of the November part of the *Astronomical Register* that that useful little publication is to come to an end this month. Originally started by the late Mr. Sanford Gorton, F.R.A.S., in 1863, it circulated for some years largely among amateurs of astronomy, its reports of the discussions at the meetings of the Royal Astronomical Society rendering it a valuable supplement to our *Monthly Notices;* while numerous communications from astronomers of eminence, both professional and private, formed a leading feature in its pages. For some eight years the *Register* enjoyed a practical monopoly of these reports of the debates at the R. A. S.; but (I think) about the year 1871 the ENGLISH MECHANIC entered the field with a monthly one of its own. If I recollect rightly, it was some time in the autumn of 1872 that the editorship of the *Register* passed from the hands of Mr. Gorton into those of the Rev. J. C. Jackson, a very able archæologist, if not a man widely known in the astronomical world. Under his supervision it continued to be the recognised organ of intercommunication among English amateurs up to the spring of 1877, when a most formidable rival to it arose in the shape of the *Observatory,* containing everything of value that the older serial did, with the addition of much that was new. Most ably edited, and possessing in some respects practically exclusive means of information, the ultimate triumph of the Greenwich magazine over any and all opposition was only a question of time; and I can only admire Mr. Jackson's true English pluck in having sustained the fight so long as he has done, and in having laboured to add so materially to what must always be a useful work of reference. Speaking for myself, I can only say that I could spare several works from the shelves of my fairly extensive astronomical library better than I could the twenty-four complete volumes of the *Astronomical Register*.

In reply to the query contained in paragraph two of letter 26492 (p. 260), I regret that I can find no record of any measures of U Cygni as a double star at all. It does not appear in Struve, Crossley, Gledhill, and Wilson's "Double Stars," in Smyth's "Cycle," in Burnham's list, nor, in fact, in any of the works in my possession. If it ever has been measured, Mr. Herbert Sadler, with his unsurpassed knowledge of stellar literature, is the only man likely to be able to reply to Mr. Baird Gemmill's question.

According to the latest balance-sheet of the City and Guilds of London Institute, to which I have been able to obtain access, the palatial building of the "Central Institute" at Brompton had cost up to December 31st, 1884, just £76,539 15s. 11d. What has been expended there since in "fittings and apparatus" I am ignorant; but, judging from a paragraph in the Fifth Annual Report of the Council, it must be something very considerable indeed. At the inception of this precious scheme, all who had the technical education of the British artificer really at heart pointed out and protested, both in the public press and on the very Council of the Institute itself, against the erection of so gorgeous a pile at South Kensington in a wholly unsuitable locality. Unfortunately, though, the Corporation of London, together with several of the wealthier City Guilds, scared at Mr. Bottomley Firth's Committee, and anxious to make for themselves friends of the Mammon of Unrighteousness, subscribed among them the sum of no less than £218,753 15s., and the astute wire-pullers who had the disposal of the money were hand-and-glove with the Ring at the "Cole-hole," in whose interest, wholly and solely, the site of the Central Institute was selected. To the objectors to the locality, who pointed out the really excellent work that was being done at the Finsbury Technical College and the South London School of Technical Art (both situated in the very midst of those who resort to them for instruction), it was replied that the Central Institute was to be on a totally different footing, and was intended for a quasi-collegiate education akin to that imparted at one of the Continental Technical High Schools. Now, though, I learn from a leading daily journal that the executive are "organising classes at their Central Institution, Exhibition-road, for the practical instruction of teachers in handicrafts," and that "arrangements have been made for a course of technical instruction, to consist of lectures on the construction and manipulation of wood-working tools and of practice in the workshop. The fee charged to teachers is quite nominal, seven shillings for the entire course, and each teacher-student is required to provide himself with a set of tools which he will be expected to keep in good order."! So, then, it was to turn out efficient carpenters and joiners after seven shilling courses, that something like a hundred thousand pounds has been expended in a palace miles removed from the workman's home—was it? Was there ever such a trumpery imposture as this? I hope to be able to get hold of some authentic returns of the number of students and of the work done after this system has been in operation for a year. If I do, I will assuredly give it all the publicity these columns will afford me—whether the Council like it or not.

If Mr. Duke (letter 26522, p. 283) has access to Vol. XLI. of the R.A.S. *Monthly Notices,* he will find on p. 47 of it an observation by Captain Noble of the transit of the shadow of Jupiter's IInd satellite, as a *brown* spot: a phenomenon scarcely explicable save on the hypothesis that that portion of the planet's disc totally eclipsed by the shadow must have been glowing with a dull red light. When the paper I refer to was read at the society, Mr. Campbell stated orally that he was observing Jupiter on the same night, and witnessed identically the same appearance. (See the last edition of Webb's "Celestial Objects for Common Telescopes," p. 425.)

"Welsh Hoghair" (query 61001, p. 292) will find a quantity of very useful rudimentary instruction in a little shilling book entitled "The Art of Landscape Painting in Oil Colours," published by Winsor and Newton, London. He may also derive many valuable hints from the Hon. John Collier's "Oil Painting," published by Cassell's. This is a two-and-sixpenny work. But he would, of course, learn more in even two or three lessons from a competent artist than he could from a whole shelf-full of books.

In reply to query 61027 (p. 293) I should not advise the use of any single-lens eyepiece at all, as it is a thing that I never have recourse to myself; an ordinary Huyghenian furnishing me with the very highest power I can ever employ. The greatest nuisance experienced in the use of a single lens is the extremely circumscribed field of view, as only a very small part of the centre of the lens is of any practical use. Having said all which, I would add that were I compelled to employ a single lens, I should have it in the form of a crossed double-convex one (as the curves would then, of course, be less violent than in the case of a plano-convex lens), with the most convex surface next to the eye.

A Fellow of the Royal Astronomical Society.

COMET *f* 1886.

[26545.]—FROM the scantiness of published observations of this comet, discovered by Barnard on Oct. 4, it would seem as though it were receiving but very little attention from amateur observers. This is probably due to the fact that one has to rise rather early, or sit up very late, as the case may be, before it is in a good position for observing; it may also be accounted for by assuming that some of the possessors of small apertures are unaware that it is visible to the naked eye, so that however small one's telescope may be, a good view of the tail and the changes it will probably undergo as the comet approaches the sun may now be obtained. The best time for seeing the comet is between 4 and 5 a.m., but it is easily to be seen (at present near Arcturus) as late as 6 o'clock; but it is needless to remind the would-be observer that he should aim to see it against as dark a background as possible. He should, therefore, look for it at the first-mentioned hours. Observing the comet this morning (Nov. 22) between 16h and 17h., with a 3in. refractor, and a power of 50, it presented the curious spectacle of having two tails, one very long one, of the same breadth throughout its length, so far as the optical means at my disposal allowed me to trace it, and a very short, narrow one on the preceding side, at an angle of about 40° with the principal tail. This small tail tapered off to a very fine point, and faded away very gradually. So far as I could see, no nebulous matter filled the space between the two. Perhaps my aperture was not large enough to show it.

Forest Gate, E. **B. J. Hopkins.**

U AND V CYGNI.

[26546.]—IN reply to Mr. Gemmill's inquiry (letter 26492), I may state that the prediction given in the *Companion to the Observatory* assigning Oct. 15 as the date of maximum of V Cygni is correctly printed. But the star has not been often observed, and its period is not yet sat sfactorily determined. Nor had I at the time of preparing the *Companion* for the press the observations made by Mr. Baxendell in 1885, and printed in the *Observatory* for April, 1886, p. 159. Mr. Baxendell found V Cygni at maximum, 1885, Dec. 30. Allowing 13 months for the period, this would make the next maximum, 1887, January 30, instead of 1886, October 15, as given in the *Companion.* I believe that the true period will be found to be somewhat longer than this, and that the star will not attain its maximum until the middle of February. Mr. Gemmill would render a service if he would keep the star under observation during the first weeks of the new year.

The spectrum of V Cygni is rather a fine example of Secchi's fourth type. The red star U Cygni shows the same type of spectrum, but decidedly inferior in beauty and distinctness to that of V Cygni. I do not know the character of the spectrum of the blue *comes.* **E. W. Maunder.**

Royal Observatory, Greenwich, S.E., Nov. 26.

THE INHERENT LUMINOSITY OF JUPITER, &c.

[26547.]—I DO not think it would be difficult to show that all numerical estimates of comparative brightness made with a wedge are inherently bad; but without entering upon that question now, I wish to point out there are two considerations absolutely fatal to any supposed visible luminosity of Jupiter. The hypothesis is that Jupiter's own light is bright enough to add considerably to the light he reflects from the sun, and that this is a consequence of his surface being at a red or white heat. I will not take Mr. Biggs's (page 255) conclusions that he is so many times brighter than he has any right to be; but merely assume that he presumes upon his position enough for his light to be perceptible as an addition to his borrowed brilliancy. Then he must give light to his satellites, and ought to make them visible in our telescopes when eclipsed; but the largest telescopes fail completely, as far as I know, to show the faintest trace of a satellite when eclipsed. Clearly, then, the inherent light of Jupiter is insufficient to make the surface of a satellite visible.

But the second consideration I have to urge is more telling. The satellites are visible in transit, and ought always to appear darker than the planet. The satellites reflect sunlight only, and sunlight, plus Jovian light, should be superior, according to the theory, to sunlight only. That III. and IV. are sometimes dark in transit does not affect the argument. They are sometimes invisible on the disc; but I. and II., as far as I know, are always visible as *brighter* beads, even upon the centre of the disc. Therefore, if Jupiter radiates light, satellites I. and II. radiate as much or more; therefore, they are red or white hot also, and therefore ought also to be visible from their own light when eclipsed. I think this is enough to completely refute the supposition that Jupiter has any visible light of his own.

We are sometimes treated to the supposition that Saturn also has light of his own; but this is negatived by the fact that the inner bright ring is brighter than any part of the ball, and, being extremely thin, cannot on the same theories be a hot and bright body.

It seems to me we are too much given to rely on our limited experience on earth in both framing and judging theories. How do we know that more reflective materials than any we are acquainted with do not exist? Our theories are, at best, deficient. Even the firmest and clearest of all—the theory of light—rests on an assumption that is sufficiently staggering—the existence of a substance that is more rigid than steel, yet permeates all bodies without difficulty.

We do well to hold these theories lightly, and to recognise our incomplete grasp of the phenomena of the universe. But sometimes objections are taken that merely prove the subject misunderstood. For instance, it has been argued the ether must prove a resisting medium, and slowly impede motion of planets and comets therein. Some have even detected retardation. But it is postulated the ether has no weight, and is entirely free from gravitation. How then can it have any effect in impeding motion in gravitating bodies? It is evidently non-existent to any such power. There can be no friction with the imponderable.

Again, we are assured no work can be done without waste. Here earthly analogy leads us astray. It is argued, the sun and the universe generally is losing energy. The sun may be; but the universe cannot. Energy no more than matter can become non-existent. The sun and every other body does exert a power continually, and without the slightest loss—the power of gravitation or attraction. If the sun loses light and heat, he must communicate it to something else. I presume if a hot body of finite dimensions had ever existed alone, and the rest of infinite space had been a perfect vacuum, the hot body must have remained hot to all eternity, since nothing existed to receive a single vibration. The solar energy only becomes light and heat now on reaching some other body possessed of gravity, for the interstellar space is absolutely cold and dark.

The sun neither heats nor lights the ether; if he did or could, none of his rays would ever light or warm us. They would all be used up on their way. We want to know much more before we can settle authoritatively anything about the waste of solar energy, and how long or how short a time it will last. E. Holmes.

ANOTHER BRIGHT METEOR.

[26548.]—LAST Monday night, on my way to our pillar-post, about 9.15, I saw a very brilliant meteor. It lit up the whole of the northern heavens with sudden and intense white light. From the position I was in, I could not be certain from what point in the sky it first started; but I saw its fall, which resembled the flow of fused metal along the line of the Milky Way in the North-West. Perhaps this was "the stray remnant" of "the unfortunate comet Biela" to which your correspondent "B. A." refers in your issue of Friday last. J. H. D.

Mount Bures Rectory, Essex, Nov. 29th.

BODIES REDUCING FEHLING'S COPPER SOLUTION—EXAMINATION FOR DIABETIC SUGAR — PAVY'S AMMONIACAL CUPRIC SOLUTION — ESTIMATION OF BORACIC ACID AND BORAX IN ADMIXTURE—DETERMINATION OF FOREIGN FATS IN BUTTER—TO CHEMISTS—OXYGEN—OXALIC ACID.

[26549.]—THE following bodies are among those which cause a precipitation of cuprous oxide when heated to boiling with an alkaline solution of cupric tartrate; in other words, are bodies which reduce Fehling's solution under the usual conditions:—Dextrose, lævulose, maltose, mannitose, milk-sugar, galactose, arabinose, gallisin, aldehyde, chloral, chloroform, valeraldehyde, resorcinal, pyrogallates, gallotannates, trichloracetates, and arsenites. Fehling's solution is not reduced by mannite, dulcite, sucrose, inosite, cellulose, dextrin, arabin, alcohol, glycerin, phenol, benzoic aldehyde, salicylic, aldehyde, formates, acetates, lactates, succinates, oxalates, tartrates, citrates, gallates, saccharates, mucates, gluconates, lactonates, benzoates, or sulphites.

In order to apply Fehling's test to urine in a reliable manner, certain precautions are essential. Albumin, if present, should be first removed by heating the slightly acid or acidified urine to boiling, and filtering from any precipitate. The liquid should then be rendered distinctly alkaline by caustic soda or potash, filtered from any precipitate of phosphates, &c., and the copper solution then employed in the following manner:—Heat to boiling in a test-tube 10cc. of Fehling's solution, prepared in the usual way, previously introducing a few small fragments of clay tobacco-pipe to prevent jumping. When boiling, add 0·5 to 1·0cc. of the urine previously treated as indicated above. If sugar be abundant, as in a decidedly diabetic urine, a yellowish or brick-red opacity and deposit will be produced. If a negative reaction be obtained, test for traces of sugar by adding 7 or 8cc. of the urine to the hot liquid, heating again to ebullition, and then setting the tube aside for some time. If no turbidity is produced as the liquid cools, the urine is quite free from sugar, or, at any rate, contains less than 0·025 per cent. If the quantity of sugar present is small—that is, under 0·5 per cent.—the precipitation of the yellow and red cuprous oxide does not take place immediately, but occurs as the liquid cools, the appearance being somewhat peculiar. The liquid first loses its transparency, and passes from a clear bluish-green to an opaque, light greenish colour. The green milky appearance is quite characteristic of dextrose.

By applying the above test quantitatively, the determination of glucose in urine may be readily effected; but it must be borne in mind that traces of glucose are found normally, or, at least, very commonly, in urine, and hence too great a stress should not be laid on the presence of an insignificant proportion.

Pavy's ammoniacal cupric solution may be used for the determination of glucose in diabetic urine, though it cannot be employed for the detection of small quantities of the sugar. Müller and Hagen determine the sugar volumetrically by Knapp's mercurial solution, which has the advantage of being applicable to samples of urine containing as little as 0·1 per cent. of glucose, while Fehling's solution cannot be applied quantitatively in the ordinary manner if less than 0·5 per cent. of dextrose be present, owing to the incomplete separation of the cuprous oxide in presence of certain obscure foreign matters contained in urine. Knapp's method is applicable in all cases, and the standard solution undergoes no change by keeping. Bodies other than glucose, capable of reducing both Fehling's and Knapp's solutions, are sometimes present in urine, but their exact amount and nature are not known.

It is a matter of indifference, so far as the application of the reagent is concerned, whether Fehling's solution be an alkaline sodic tartrate of copper, an alkaline potassic tartrate, or a mixture of the two. The amounts of caustic alkali and alkaline tartrate need not be rigidly those prescribed.

The action of reducing sugars on Fehling's solution is not precisely known, but among the products are:—(1) Acetic and formic acids; (2) certain non-volatile acids, especially tartronic, an acid forming uncrystallisable salts, and an acid decomposed with formation of humus-like products on heating its alkaline solution; (3) a gum-like substance.

It is true that in Pavy's ammoniacal cupric solution the copper does less duty than in Fehling's. As the reaction is complex and not fully understood, it is not possible to give an explanation of the fact. The presence of a varying proportion of salts, such as alkaline tartrates and carbonates, gravely affects the accuracy of the indications obtained by Pavy's solution.

I may perhaps be excused if I follow the usual custom of giving my authority, and state that I have copied the foregoing information on the employment of alkaline cupric solutions almost *verbatim* from Allen's "Commercial Organic Analysis," Vol. I. pages 225, 229, 285, 286, and 451.

In reply to query 60919, page 269, addressed "To Mr. A. H. Allen," the proportions of borax and boracic acid in a mixture of the two can be determined as follows:—Ignite a known weight, and note the loss, which is water. Dissolve the weighed residue in water, and titrate the solution with standard mineral acid, using methyl-orange as an indicator. Calculate the Na_2O found by the titration to $Na_4B_4O_7$, and the difference will be the B_2O_3 in excess.

The butter fat yields an average 88 per cent. of insoluble acids and butter substitutes 95·5, the difference, 7·5, is the rise caused by an entire change from butter to butterine. Hence a rise of ·075 per cent. in the insoluble acids corresponds to 1 per cent. of butterine. Therefore, if the excess of insoluble acids over 88 per cent. be divided by ·075, the result will be the probable percentage of butterine. But $\frac{1}{\cdot 075} = 13\cdot 3$. Hence, if F be the foreign fat and I the insoluble acids, $F = (I - 88) \times 13\cdot 3$. The factor is purposely made low so as not to cause over-estimation of the butterine.

Query 60899, addressed to "Chemists," has been answered completely and accurately by "E. F. S." (page 289), and so far as the reaction between ferrous sulphate and bichromate is concerned, by "F. C. S., Liverpool" (page 269). But "I wonder, oh! I wonder," what could have induced "Wis" (page 269) to fancy his equations had anything to do with the question asked. In addition, "Wis" should make the reaction formulated in his second equation the subject of a scientific paper, if on *trying* the experiment he finds the "event comes off."

"Oxygen," query 60936, though formerly prepared from manganese dioxide, as described by "E. T. P.," in his interesting reply (page 289), is now best obtained from potassium chlorate, which is much cheaper than was formerly the case. If the Polytechnic, the place to spend a happy day, were ever to be resuscitated, I fancy they would not return to the use of manganese; but would probably obtain the oxygen from barium dioxide, or indirectly from the air, according to Brin's process. In the theatres, many of which I should think must use quite as much oxygen as the Polytechnic ever did, I believe chlorate is universally employed. If not, will someone put us right on this point?

"Oxalic acid" (query 60940) is now always obtained by the sawdust process, and the manufacture is carried on by one or two firms only, with whom a manufacturer of oxalic acid from sugar and nitric acid would have no chance of competing. With an appropriate mixture of caustic potash and soda, sawdust yields half its weight of crystallised oxalic acid; but with caustic potash alone wheat bran is said to yield 150 per cent. of its weight of oxalic acid. The fullest description of the process hitherto published is that in Roscoe and Schorlemmer's "Treatise on Chemistry," Vol. III. Part II. Alfred H. Allen.

Sheffield, Nov. 27.

HOW A BOY MAY RAISE A SOLID TON WEIGHT WITHOUT MACHINERY.

[26550.]—IF "B. R." will read the letter on p. 262 again, he will see that the question is not "whereabouts" is the boy; but really where can so phenomenal a "boy" be found. If it is possible to raise a ton weight by putting a strain of 10lb. successively on each of 224 strands or yarns, it would be as well to demonstrate it. Perhaps "B. R." can tell us how he knows that the strain is only 10lb., and how many "yarns" it is necessary to strain before the ton begins to lift. No doubt the boy will have to be on the deck—very much so; and when there can tell his "yarn" to the marines; for he will not succeed in lifting the ton unless he puts a strain of 10lb. *simultaneously* on each of the 224 strands. Nun. Dor.

EXPRESSION IN ORGAN-PLAYING.

[26551.]—I OBSERVE that Mr. Audsley, in his very able and suggestive article on the Chamber Organ, speaks of the swell as if that, as a matter of course, were the essential means of expression on the organ, and, indeed, begs the question by calling his swell pedals "expression levers."

But is it quite so clear a case? While no one can be more sensitive than I am of the immense additions to the resources of the organ furnished by the invention by which the old "Echo" became the modern "Swell"—it is a pity it was not content to retain its old and appropriate name—I apprehend there is at the present time some danger of the swell being elevated into an undue position at the expense of what is, after all, the organ proper.

It is common to hear the organ spoken of as an expressionless instrument; but I cannot believe that Bach or Mendelssohn thought it so: they would hardly have written the many emotional passages to be met with in their organ works for performance on an instrument which could not give them utterance. If anyone were to play (say) a fugue unintelligently, without realising the entrances of the subject and answer for instance, it is certain he would never make his audience realise them. On the other hand, a sympathetic player, by the subtle delicacies of touch, the more or less *legato* and *staccato*, anticipation, acceleration, retardation, &c., will make himself felt, though he may scarcely be able to tell how beyond what he himself feels. *Si vis me flere, fleto.* I do not say for a moment that the swell is not a valuable assistance in aiding expression, but that it is not of the essence of it, and that without the sympathetic touch it is useless or worse.

It is not to be forgotten that the swell attains its effect by what is really the more or less muffling, and consequently deterioration, of the tone. The case is analogous to that of a band under the stage, or a singer behind the scenes. With the shutters fully open it is still at the best an organ confined in a chamber; that a stop of moderate power heard through a closed swell box is by no means the same thing as a really soft stop, will be recognised by anyone who is acquainted with the exquisite "Echo" organ at Doncaster; while in the effect of *crescendo* and *diminuendo*, excellent as that effect is within moderate limits, if these are overstepped, so far from the expression being aided, there is suggested rather the obtrusive lifelessness of an automaton.

I do not understand Mr. Audsley to advocate inclosing the great organ except in chamber instruments; but I confess I am unable to follow him even there. In my own case (where the organ was designed with the single purpose of rendering organ music proper, as adequately as might be on a small scale), I have a great organ commencing with a 16ft. covered and two 8ft. metal open stops throughout, and on a heavier wind than Mr. Audsley advises, entirely uninclosed; and, so far from finding this excessive, I could ill afford to lose its freshness and vigour, and the contrast thereby afforded to the swell.

But, like all facilities, the swell has its nemesis, and to deal with this is the practical point. That the swell stops should be voiced to a somewhat pungent tone is natural enough, for otherwise they would be apt to sound faint. It is also, perhaps, not unnatural that the organist should avail himself of a contrivance which enables him to pull his choir together, or augment or reduce his quantity of tone at a moment's notice, without taking his hands off the keys, and therefore uses his great and swell continually coupled—though to the listener this is about as tedious as if in the orchestra the reeds played throughout with the strings. The organ builder, knowing his great organ will seldom be heard without the swell, naturally voices its stops so that they shall assert themselves against the latter; hence the prevalent forcing and overblowing, so utterly destructive of the dignity and volume which should characterise the great organ.

After all that may be said as to the mellowing of pipes, by age, if there were really much in this, why do not builders "lay down" pipes after the manner of wine-merchants; plenty of customers would be ready to give a good price for a "fine old" diapason of such and such a year—and after all that is to be laid to the score of bad metal, bad scales, want of skill, and want of taste, I have a shrewd suspicion that the deterioration in voicing which Mr. Audsley laments is largely due to the swell-box and the inevitable coupler. I have met with organists in Germany who have told me they never made use of couplers, either manual or pedal—"they were not necessary." Without going so far as this, I cannot help thinking to make the great organ always complete in itself, and let it be

more generally heard on its own merits, would be a step in the right direction.

Again, it is mainly to the facility afforded by the swell that we owe the so-called "orchestral organ." Let it be now understood that the organ is an instrument *sui generis* and *sui juris* with a repertory of its own (and a worthy one), and that there are certain things it can do beyond comparison better than any other instrument, and it follows that to abandon its own special functions and to go in for imitating something else is a derogation. No doubt there is plenty of music not originally written for the organ which lends itself to the genius of that instrument. Handel is said to have frequently used the theme of one of his grandest choruses as a subject for extemporisation. Mendelssohn used the theme of one of his sister's songs in his sonatas. He played on the organ at Buckingham Palace a chorus from one of his oratorios; but it is one thing to adapt suitable music to the organ and quite another thing to seek to adapt the organ to music properly appropriate to other instruments. When one finds organ builders devoting the ability they might bestow on the perfecting of tone and mechanism to imitating all the instruments of an orchestra, and organists doing their best to persuade their audience that it is a band they are hearing and not an organ (in which latter point they unquestionably succeed) is there room to doubt that art and skill are tending in a wrong direction?

Nov. 24. **Finem Lauda.**

HEATING WATER RAPIDLY.

[26552.]—"U. S. A."—The late counsellor, Charles Wye Williams, the founder of the City of Dublin Steam Packet Company, adopted the plan of studding over with rivets the roof of the furnaces in some of his steamers at the Clarence Dock in Liverpool, about 50 years since. It was, however, an experiment which did not last long. As well as I can recollect, the rivets projected downward about 3in., and were 4in. apart each way; that the effect was good for so much, but that the rivet heads burnt away with great rapidity.

I may here mention that the "counsellor" adopted an excellent plan with the smith's fires: by mixing Irish peat or turf from the "Bog of Allen" with the "blazey" Liverpool coal, coking the mixture in kilns constructed for the purpose. This fuel gave remarkably clean, mellow heats, much better than when using coal alone.

Nov. 24. **R. J. Lecky.**

[26553.]—THE writer of the note on p. 255 of a recent issue has evidently read only an imperfect extract from my paper on this subject. The use of studs or rivets on boiler plates to increase the heating surface is at least twenty years old in this country; but no experiments have ever been published giving the exact value and proportions of these studs, nor has their action ever been properly understood. I claim no novelty as to the use of studs; the questions which my experiments were intended to settle were the correct proportions of the studs so as to admit of flame contact, and the value of the surface in contact with the flame as compared with ordinary boiler surface. The further experiments on this subject have shown that an ordinary surface with water behind is absolutely untouched by the fiercest blast flame directed against it. The thickness of the inert space or cold zone is easily measured.

My experiments were not, as the writer appears to suppose, a recommendation of any special form of heater, but a search into the unknown space between a water-vessel and a flame. The matter is one of great practical importance; few are aware even of the existence of such a space, and none understand the condition of matters in this space. My first experiments demonstrated its existence, the possibility of passing or destroying it under certain conditions, and the results obtained in increased duty, surface for surface. The matter is by no means at an end, and my experiments are far from being concluded.

Thos. Fletcher.

"F. A. M.'s" LATHE DESIGN.

[26554.]—IN regard to "Vulcan's" letter on page 218, in which he refers again to the reversed slides of the upper part of my proposed slide-rest, I have another reason for that form. I am keeping in mind that when using the driller for slot-drilling or milling on the face-plate, it will be necessary to mount the driller so that its centre may be below the lathe centres. I think this might be done in my arrangement by winding back one or both the top slides, and then pulling them off. Pulling off the top slide would leave a platform $\frac{3}{4}$in. below the usual height, which might often be sufficient; pulling off both slides would leave a platform $1\frac{7}{8}$in. below (say 2in.), and this is half the travel of the vertical slide. I do not forget that these are scraped and fitted surfaces, but do not see why it should injure them to bore and tap two holes in their upper surfaces, and clamp down upon them a filed-up drilling spindle. The advantage of being able to take them off quickly now becomes important. "Faber" (page 265) thinks it would be better to form these slides so that the upper part should be supported upon a shelf or ledge on the lower one, as well as upon the top surface. I believe it would be better to do this for the front edges; as it would bring the rigid support $\frac{5}{8}$in. further forward towards the tool-point. It would, however, increase the cost a little.

Another correspondent thinks the upper part of the rest unequal in strength to the lower. I think that is true, and it arises from the vertical slide having been made gradually stronger to meet the criticism of several readers. I consider it now a little over-strong—a good fault, if it is one; the upper part of rest is as strong as that on my present 5in. back-geared lathe; therefore, this should surely be sufficient for a lathe without back-gear.

As to the mandrel-nose I cannot make up my own mind, and often go back to the cone fitting with wedge or screw-ferrule.

No doubt an eccentric fastening would do very well to secure the traverse-slide; I think the screw somewhat simpler, and if the handle began to come against the webs it would only be necessary to put in a thicker washer.

The taper set pins for the circular movements are good. I intended to use one to the smaller flange: it is more difficult to get it into the other, as it would have to go up from beneath, and I intend to dispense with it. I keep in mind the suggestion about fixed levers to dispense with spanners; but should be rather afraid to try the spring snaps. I am glad to have "Faber's" suggestions, and to see that he approves of the design. I have not gone forward with the other parts of the design; but intended to follow Messrs. Cooke's practice for the loose headstock, and perhaps, too, for the back motion, which they use instead of an overhead; but am not quite sufficiently clear about it yet. Perhaps "Vulcan" will kindly undertake the moving headstock design.

I saw last week the famous Cooke lathe, which has been described at length by Dr. Edmunds in these columns. I might say a good deal about it; but for the present will only say I was delighted with it, and thought if only it had our vertical-slide it would be perfect. **F. A. M.**

TRICYCLE MATTERS.

[26555.]—IN reply to "Gamma Sigma" (26536), the reasons why small wheels are preferable to large is that the tricycle can be made so much lighter, and there is less resistance by the front steering wheel. There are also other reasons. If a tricycle be 40in. from driving axle to steering axle, the driving wheel 40in., and the steering wheels 20in. diameter, the pedals being about 15in. in front of driving axle, it is obvious that when any work has to be done most of the weight is thrown on the pedals, putting too much strain on to the little wheel, causing frictional resistance on its axle. This has been altered in the new bicycle, which drives on a 30in. wheel and steers on a 31in., making it a very fast machine, as there is so little frictional resistance to the driver by the front steering wheel; but to make this change successfully in a front-steering tricycle is another matter and the subject of patents.

R. G. Bennett.

[26556.]—I SHOULD like to add my mite to this discussion, and first with respect to "Country Parson." I am glad to find he approves of the Crypto gear. I always understood it was, in addition to its expense (£6), very complicated, and likely to go out of order. I have been using Bown's two-speed gear now for 18 months. It has done many thousands of miles in that time, and never gone out of order. In a hilly country, and with wet roads, I look upon two-speed gearing as almost a necessity.

I may tell "Gamma Sigma" of a better way than pushing his machine uphill. First, you must fit your machine, if it is not already fitted, with an automatic steering apparatus. Mine is exceedingly simple, cheap, and effective. My machine is a two-track front-steerer. About the middle of the steering rod a small iron eye is clamped on with a screw. Attached to this are two pieces of round rubber $\frac{1}{4}$in. diameter, and about 9in. long. They are arranged with wire eyes at either end, like rubber door springs; they are attached by their other extremities, one to the Stanley head of steering wheel, and the other to the socket of steering handle. A little adjustment of the clamp on the steering rod makes the wheel run perfectly straight, and still the spring is not strong enough to cause any perceptible increased effort in moving the handle. It is not unsightly, and with some modification adaptable, I should think, to any front steerer. If "Gamma Sigma" will now get a strap 3ft. long, with a loop at one end for the hand and a small ring at the other, unscrew the nut on top of Stanley head, put the ring on and screw down nut again, he will be able by means of this strap, when he comes to a steep hill, to step off his horse, and without allowing it to stop, walk up pulling it after him, and so save both time and labour, for I find it is less labour to pull the machine up a hill than to push it, though I cannot tell why.

Doctor Medicinæ.

WIND POWER.

[26557.]—THERE has been a good deal said lately in the mechanical journals about wind power and horizontal windmills, and especially in your own very instructive columns, from which I glean a good deal of information that is both new and useful to me—albeit, my years would suggest my being a teacher rather than a learner in mechanical or any other science. But your contributors give us very little that is tangible upon which to exercise our invention in regard of wind-power, and this I find tantalising. They tell us something and leave us to guess the rest.

For instance, Mr. Albert Collingridge, in your impression of the 19th inst. (60817), p. 267, partially describes a model machine of that kind, which he himself set up, and which "worked very satisfactorily." He informs us that it had six horizontal arms, carrying vertical sails, *at the end;* and he gives us to understand that these sails were constructed after Mr. P. Vallance's invention on the venetian blind system, as when it was wanted to stop "one central rod opens all the louvre boards." And there he leaves us. The inquiries one would like to make of him, with your permission, are—What was the length of the arm from the centre? and what portion of it was occupied by the sail at the end—length and breadth? And is it to be seen anywhere? And what did he drive with it? Before laying down my pen, may I be permitted to call attention to the perplexing accounts we get from philosophers and experimentalists as to the force of wind? It has been understood—I need not quote authorities—that an ordinary gale of wind, or close-reefed top-sail breeze, exercises a pressure of about 8lb. to the square foot, and that below this wind-power is useful in mills down to a pressure of 1lb. to the square foot. But if I remember rightly, when the Tay bridge was destroyed, the Scotch meteorological establishment, on the Grampians, recorded a pressure that night of 11lb. to the square foot, and that was a gale which strewed the land with fallen timber. The gale of 15-16th October last has left fewer ravages after it. Yet at the meeting of the Meteorological Society on Wednesday, the 17th inst., at the Institution of Civil Engineers, Mr. C. Harding read a paper on that gale, in which he stated that in the squalls the pressure was equal to 70lb. on the square foot. Velocity, 120 miles per hour. Will nobody reconcile these contradictions for us? For myself, I may say I have watched express trains running before a strong gale in the open country, but I never saw their cloud of steam overtake them. **Raymond Browne.**

"MICROSCOPICAL ADVANCES."

[26558.]—DR. ROYSTON PIGOTT has been writing under the above heading on what he calls the transcendental definition of modern object glasses. I confess I have not been able to understand him, although there may be some who do; but I cannot help thinking that it would have been much more to the purpose had he taught the possessors of humbler glasses how to get at the best points of their definition. Microscopes are now made by the thousand in this country fitted up with two excellent object-glasses, the cost of which, with the stand, does not exceed that of a first-class $\frac{1}{4}$in. objective of wide angle with screw collar correction for covered and uncovered objects.

It is a commonplace of all the textbooks that the thickness of a glass cover will break down the corrections of a wide-angled lens; but it may not be so well known that so delicate is the working of even a cheap $\frac{1}{4}$in. of narrow angle that the difference between a thin and very thin cover on the object is quite sufficient to materially affect the definition.

My attention was lately called to this in a forcible manner when examining some living bacteria with a low-angled lens of about 80° and without correction collar. With a cover of a certain thickness the whole field sparkled as if each bacterium shone with its own light; but when a thinner cover was substituted, or the image was rendered dull and uninteresting, I certainly could see the objects, but the crispness was lost.

I am well aware that this is no new discovery, and must be known to every expert in microscopy; but that it is not known to a large number of workers in these humble instruments is probable, their very construction leading the observer astray, for if a length of body ranging from 6 to 10in. w[illegible] make no difference in the definition, surely a little difference of cover cannot affect it injuriously. That it does, I have endeavoured to show.

By the bye, Sir, what has become of all the readers of "Ours" who used to discuss matters microscopical so vigorously? That the fault is not in the Editor we know, as hardly a week passes without some article of interest on the microscope appearing; but there the matter stops, and the general contributors seem to discuss every subject but that one. **T. F. L.**

THE RELATION BETWEEN BATTERY POWER AND THE LIGHT GIVEN BY LAMPS.

[26559.]—I HAVE been very much amused in the course of the last few weeks by the very extraordinary notions that seem to prevail with regard to what light can be got out of a given battery or cell and a given lamp. We have, among others, two classes of inquirers in our paper—viz., those who expect too much, and those who doubt everything. The former remind me of the man who set his donkey to draw two tons of coal, and was surprised that it didn't. The latter, if a fact is in any way new to them, set to work to deny it, doubt it, question it, but never fairly try it. Four years ago the bona fides of Mr. Tolman and other pioneers in the way of small dynamos was actually doubted by these clever gentlemen; and the fact of the possibility of lighting four 5c.p. lamps from the lathe was set down as being "that which is not!" To the former class belong those who wish to light a palace of 15 or 20 rooms from an accumulator to be charged from a lathe, or who ask if it be possible to use a dynamo to light lamps and to work a motor which shall drive a lathe, sewing machine, and the said dynamo all at the same time, and when not wanted for the two former may be set to work a sausage-machine and charge accumulators for future use. But the doubters are infinitely more injurious to the young student than are the enthusiasts. Most of these doubters know something of the subject, and that little knowledge is to them and others a dangerous thing.

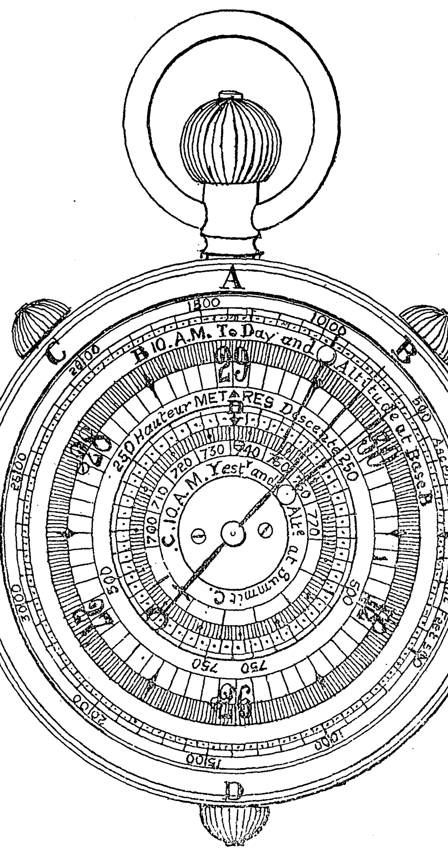
Let us take, for example, the case of the lamp which my friend Mr. Bowron honoured by calling "Wonderful." I had been making some experiments with chromic acid as compared to potassium bichromate in the single-fluid battery. Having by me a certain lamp (not for sale) by a German maker, I used that in making the comparative trials of the lighting powers of the two forms of battery. I gave the results as I found them—viz., that while with potassium bichromate I was barely able to redden this lamp, with chromic acid I was able to light it well. Now note how the doubters interpreted this. One said, "It is not chromic acid at all, it is the old red salts." Another said, "That must be a wonderful lamp, if it light up with ⅘ of an ampère," and so on. To prove my bona fides, I offered to let anyone see the experiment at my own place (I could not sell the lamp, as I had but one). Several came, and two gentlemen reported their experience in the ENGLISH MECHANIC.

I have also tried Messrs. Shippey's lamps, and though I do not consider them "wonderful," yet they are, as battery lamps, far away superior to any that I used, with the sole exception of the one which I mentioned above. Messrs. Shippey Bros. have evidently understood that with batteries it is easier to get a large current than one of high voltage, or rather, to speak more correctly, that a battery consisting of few cells is more convenient than one consisting of many. These low-resistance lamps are eminently adapted for battery work, and as long as amateurs like to use battery power for experimental work, so long will there be a demand for lamps of low resistance, even if they require a few more ampères. In purchasing incandescent lamps, special care should be taken to mention whether they are for use with dynamo or with battery. In the former case stating the E.M.F. of the dynamo, and the number of lights required; in the latter, stating the kind of battery with which it is going to be used. In this way it is possible to adapt the resistance of the lamps to the special purpose required. **S. Bottone.**

IMPROVEMENTS IN POCKET BAROMETERS AND THERMOMETERS.

[26560.]—BEING dissatisfied many years ago with the method of setting the pocket barometer by sliding round a marker on the revolving rim by the hand only, I had the pendant winder attachment applied to the marker instead (A).

I subsequently added a vis-à-vis pendant winding knob (D) which rotates a French mètre scale for altitude purposes abroad, and I also added a fixed barometrical scale in mètres. Finding these very successful and convenient, I finally added two more winding knobs (C) to mark 10 a.m. yesterday and altitude at summit and (B) to mark 10 a.m. to-day and altitude at base. It will be seen that these two markers serve over both the English and the French scales, both altitudes and barometrical. The altitude scale marks ascent to 3,000ft. and 2,000ft. of descent, and for greater heights the two scales are so arranged as to serve together up to 5,000ft. To avoid the expense of hall-marking, the case, except the back, is made by laying pure gold on a metal core by electricity until the desired weight of gold is attained; the back is sheet gold affixed to metal interior, and the whole is then coloured uniform. By this device the gold pocket barometer in the accompanying photograph—real size—is produced for £16 16s. (the last before, with its gold case made in usual way and hall-marked, having cost upwards of £22.) I have had three made in gold cases of this perfected type. I lately passed through the St. Gothard with one of these barometers in my hand, and on arriving on the Lago Maggiore the instrument recorded on its face, by means of the various markers, the respective altitudes of the Swiss level at starting, of the summit of the St. Gothard Pass, and of the Italian level on completing the descent on the other side, besides leaving pendant marker A still free to mark the variations of the barometer hand on weather account. Having the facility of comparing all local readings by its possessing the mètre scales as well as those in inches and feet, added to the interest of this most pleasant travelling companion.



In another pocket I carry a pocket thermometer which I have devised, of the size and shape of a pocket pencil-case only, consisting of a mercurial glass tube fixed in a silver tube, with a wide portion removed to show the reading engraved on the glass tube on Fahrenheit scale; alongside this scale, left and right, are engraved on the silver tube Reaumur and Centigrade scales respectively. The three scales can thus be read and compared simultaneously, while the whole slides for safety into an outer silver case. This costs about 13s. in silver; but anyone can, of course, make either of these instruments in any metal. **Montmartre.**

RATS AND HEDGEHOGS.

[26561.]—IT is only by experiment that we can learn the value of our surroundings. A short time ago the idea struck me that rats would not be amiss as an article of food, so, having procured, by the aid of my terrier, a couple of plump barn rats, I proceeded to break their necks, skin them, and presented them properly "dressed," decapitated and winged to my housekeeper. That worthy soul expressed infinite wonder at the diminutive size of the *rabbits* in question, and ventured so far as to ask what I had given for "them harticles" with that supreme contempt for my marketing shrewdness that only housekeepers can express. In explaining the genus of my "harticle," her wonder changed to horror, and it was only by the aid of "two drops on a lump of sugar" that she could be induced to proceed to the operation of cooking. I have not recovered my prestige in her eyes for even touching such "loathsome creeturs." It has in fact, been *casus belli in re rat*. But the rat made a most delicious pie, and was voted a luxury by some friends who partook unwittingly. As a trophy of my feast I have cured the skins, and kept a few embryo rats I found in one. I have since eaten a hedgehog stewed in milk and onions, and can safely recommend this dish as a real delicacy.

Nov. 25th. **W. Stanley Smith.**

DIATOMS—VEGETABLE OR NOT?

[26562.]—"LONDINIENSIS" (20539) cannot have had much experience as an observer of the lower forms of life, or he would not have been so much surprised by the movements of a *Navicula*. The power of motion is displayed more or less freely by nearly all diatoms and desmids, as well as by the zoospores of algæ.

Proof of the vegetable nature of diatoms is afforded by the facts that they derive nourishment from inorganic matter in water or air, and that under the influence of sunlight they liberate oxygen by the decomposition of carbonic acid.

There is grand unity in nature, and no hard line of demarcation can be drawn between animals and plants, for as Rolleston says, "There are organisms which at one period of their life exhibit an aggregate of phenomena such as to justify us in speaking of them as animals, whilst at another they appear to be as distinctly vegetable." However, the life-history of diatoms is known, and, by general consent, they are now considered as unicellular algæ. **W. H. Shrubsole, F.G.S.**

A DISCLAIMER — OPERA-GLASSES, MICROSCOPE LENSES, &c.—TO "PRISMATIQUE."

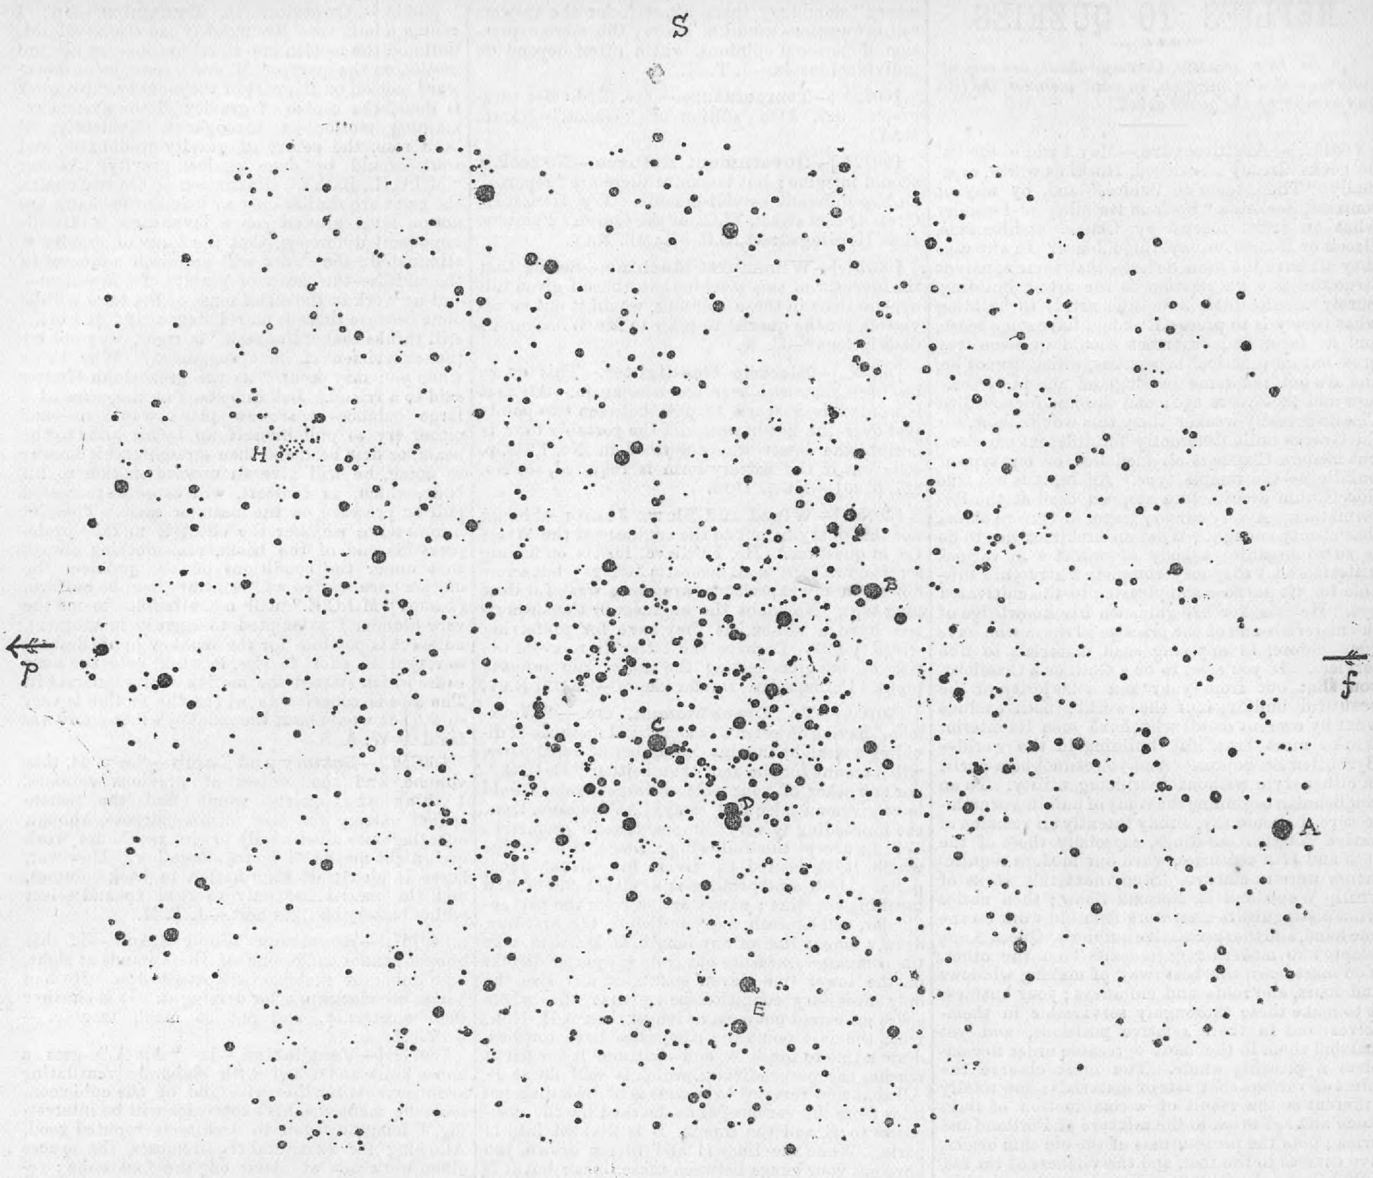
[26563.]—WILL "Prismatique" kindly refer to the leading article in the *Photographic News* for the week before last *re* micro-lenses for photo-micrography? The author of those remarks, Mr. Bolas, is a staunch upholder of Great Britain and of her productions. I note that "Prismatique" feels hurt that Mr. Holmes should think him an interested party. Will he allow me to disclaim all interest in lenses, whether opera-glass, field-glass, or microscope objectives, except *scientific interest?* **S. Bottone.**

INVENTIONS AND PATENT LAW.

[26564.]—IF "R. S. T." (letter 26533, page 285) will refer to "An Elementary Treatise on the Combustion of Coal," Weale's series, 1st edition, he will find that chapter XVII. gives an account of a method of increasing the heat-transmitting power of boiler plates by the insertion of studs in the parts exposed to flame.

The original idea seems to have been taken from the popular impression that a three-legged pot boiled sooner than one without legs. A pot with twenty legs was made, and it was found that water boiled more quickly than with three.

In the *Mechanics' Magazine* of 1842, an account will be found of experiments made with gas-



A portion of M.M. Henry's Photograph of the Cluster M 35. Geminorum (G.C. 1360) and outliers.

Diameter of Field, p to f., 1° 7'.

N

burners and suitable vessels. First, without studs; second, with studs on one side of the plate only; and, third, with studs projecting on both sides of the plate, the result being the same that Mr. Fletcher has found.

The plan has been tried with success in, at least, two steamers—the *Royal William* and the P. and O. boat *Pacha*. My authority for these statements is the treatise above mentioned, and it is evident that the idea has been carried beyond the experimental stage, and that a patent would be barred.

Richard Dresser.

THE CLUSTER MESSIER 35 GEMINORUM.

[26565.]—The beautiful cluster M 35 Geminorum, (G.C.) 1360, is one of the most charming telescopic objects visible in a comparatively small instrument, owing to the size and configuration of its component stars. First noticed as a cluster on the maps of Flamsteed and Le Monnier, it is described by Messier in his celebrated catalogue of nebulæ as merely a mass some 20′ in diameter of very small stars near the left foot of Castor. It was observed on several occasions by Sir W. Herschel, and is described by his son as a "large, coarse, pretty rich cluster of 9 to 16 magnitude stars, which fills two or three fields, but chiefly one in which are about 100 stars." Smyth appears first to have noticed the remarkable curves and loops formed by the larger members of the group. "It presents," he says, "a gorgeous field of stars from the 9th to the 16th magnitude, but with the centre of the mass less rich than the rest. From the small stars being inclined to form curves of three or four, and often with a large one at the root of the curve, it somewhat reminds one of the bursting of a sky-rocket." Secchi's description of its appearance in the 9⅗in. achromatic at the Roman College is not unlike Smyth's. "Gruppo largo, e composto di belle stelle, la maggior parte delle quali sono misurabili. Ha forma curiosa di archi incrociati e fantastici; la parte principale contiene almeno un centinaio di stelle superiori alle 12ª gr.; qui ne diamo solo un cenno delle principali per servire a fare una mappa della parte più lucida. . . . . è meritamente un oggetto sorprendente e di quelli in cui, attesa la sua configurazione e la parte del cielo ove si trova, vi è speranza di trovare movimenti." He gives measures of some twenty-four stars of the group; but I am not aware that it has ever been figured as a whole. Every possessor of Webb's "Celestial Objects" must be familiar with Lassell's account of its appearance in his 2ft. reflector, while in the 6ft. at Parsonstown it was seen as a magnificent cluster in a rich field. The observer there estimated that 300 stars were visible in the finding eyepiece, diameter 26′; many of them not being below the eleventh magnitude. It has been photographed by Mr. Espin with the 4½in. camera belonging to the L.A.S., and by MM. Henry with the 13⅜in. at Paris. I append a rough tracing of its appearance in the exquisite picture obtained by the French astronomers, and I trust that the engraver may be able to produce a more satisfactory representation of the component stars of this beautiful mass than in the case of the clusters in the sword handle of Perseus, the illustration of which, on p. 65 of the present volume, is anything but a thing of beauty and a joy for ever. The star marked A is rated 6·7 mag. in the *Durchmusterung*, B 8·4 mag., C 8·5 mag.; the northern star of the wider pair, E, 9·3 mag.; and the southern one 8·5 magnitude. The pair D is OΣ 134, the northern star being rated 7·0 by OΣ, 6·8 by De, 8·2 by Argelander, and 8 by Bessel. The southern and smaller one of the pair (between which a much smaller star is visible on the photograph) is rated 8·2 mag. by De., 8·3 mag. by OΣ, and only 9·4 mag. by Arg. The smaller star is blue according to Dembowski, and is 31·0″ distant from its bright yellow neighbour, the position angle being 187·9°. The letter H points out the faint little cluster Ḥ VI. 17, termed by its discoverer a miniature of its magnificent neighbour.

November 19th. **H. Sadler.**

Chinese Edge Tools.—At a recent meeting of the Council of the Birmingham Chamber of Commerce a communication was read from the Foreign Office, accompanying a collection made by Mr. O'Connor, the British Chargé d'Affaires at Pekin, of Chinese picks, hoes, spades, hatchets, trowels, and sickles, a plough coulter, and several specimens of razors manufactured and used in China at the present day. Mr. O'Connor is of opinion that these articles could be made in England at less cost than in China and of equally good quality, and that if consigned to the care of intelligent agents in China they would find a ready sale there. The examples in several instances, more particularly the picks and hatchets, resemble patterns familiar in this country, but are of much rougher make. The spades, hoes, and trowels are the most primitive, and are very roughly fashioned, for the most part out of rough sheet iron, and there is little doubt that while preserving their general form English tool makers will be able to turn out a superior article at a lower rate than they can be produced by native hand-work. It was resolved to place the articles on view at the Birmingham exhibition, and to invite the inspection of local tool and implement makers.

The amount of crude platinum mined in America in 1885 was about 250 troy ounces, valued at 187½dol. This is exclusive of about 300 ounces of irid-osmine, for pointing pens.

REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[60432.]—**Architecture.**—May I add to the list of books already mentioned, Ruskin's works, especially "The Stones of Venice," and, by way of contrast, Beckett's "Book on Building"? I wonder what an artist means by Classic architecture, Greek or Roman, or, say, Inigo Jones? In any case they all have the same defect—that their apparent structure has no relation to the art of building. Surely architecture, as a fine art, is to building what poetry is to prose: it should have some sense, and its form and ornament should in some way grow out of practical necessities, which cannot be, and are not, the same in England and in Greece, now and 1800 years ago; and the case for so-called Classic is really weaker than this would show, for the Greeks built differently for different purposes, but modern Classic is all modelled on one type of buildings—the temple type. Again, it is not true that Gothic architecture stopped dead at the Reformation. A very cursory glance at Oxford shows that clearly enough. What an architect has to do is so to organise a body of workers in various materials that they may complete a structure suitable for its purpose and pleasing to the cultivated eye. He has for his guidance his knowledge of the materials and of the practice of those who have gone before, in applying such materials to like services. If you elect to be a Goth or a Classicist, you shut out from your ken a majority of the beautiful buildings of the world; both exclude what by consent of all who have seen its interior is the most beautiful building in the world—Byzantian St. Sophia. And you cannot be a purist in either style without sacrificing utility. To an Englishman beginning the study of building or architecture, I should say, Study intently all remains of native English buildings, especially those of the 16th and 17th centuries, when our modern requirements were in embryo. Study next the works of Philip Webb and R. Norman Shaw; then notice what distinguishes their work from old work on the one hand, and the speculative builder's "Queen Anne adapted to modern requirements" on the other. You must learn the best way of making windows and doors, and roofs and chimneys; your business is to make these thoroughly serviceable in themselves and in their relative positions, and yet marshal them in the most agreeable order to complete a pleasing whole. You must observe the effect of various contrasts of materials; how totally different is the result of a combination of Bath stone and red brick to the mixture of Portland and brick; note the pleasantness of the old thin bricks, five courses to the foot, and the vileness of the fat, half-baked suburban, fit only to be plastered over; see with your eyes how the sunny effect of whitewash is chilled to skim milk by the addition of blue-black, and hate that penn'orth of blue black to the dozen of whiting as an inartistic, unscientific abomination, and here and everywhere strive after pure clean colour, for it is by matters of execution such as this that a design is made or marred, and not by antiquarian erudition or classicism coldly correct. Originality neither seek nor avoid; seek only the best way of doing the work, whether traditional or novel. And throughout you have got to consider not only your own likings; but the prejudices and capabilities of the workmen through whom you work, for architecture is a co-operative art, like generalship, and many of us have had to exclaim with old George Stephenson, "It's hard to engineer men!"—W. A. S. B.

[60592.]—**Setting Axle** (U.Q.)—Does the querist mean cart and waggon axles? If so, give the height of wheel, dish and spoke and length of box; I will see what I can do to help him. Say what kind of axle; if patent axle, diameter of stock.—J. C.

[60711.]—**Rendering Ground Glass Transparent.**—If this job is worth doing well, I would suggest that it might be advisable to repolish the "ground" parts, first with the very finest emery, and then with rottenstone and oil. Good pale copal varnish would do; but no doubt Canada balsam would be better. Of course, I am assuming that there is a difficulty in removing the two glass panels: otherwise it would be best of all to replace them with transparent glass.—NUN. DOR.

[60714.]—**Testing Ventilators.**—What does this querist mean by "testing"? The velocity of the air current is measured with a small anemometer.—NUN. DOR.

[60716.]—**Choral Top.**—The questions of "S. S." cannot easily be answered without inspecting the so-called choral top. If he has one, surely he ought to be able to answer several of them himself.—E. G. M.

[60720.]—**Zirconia Cylinders.**—These cylinders are in use by many lanternists; but "Limeweary" should try them himself, for the answers to his questions would be mainly the mere expression of personal opinions, which often depend on individual tastes.—J. T. M.

[60723.]—**Temperature.**—Yes, 5508. See paragraph 327, 11th edition of "Ganot."—SAML. RAY.

[60727.]—**Government Returns.**—No book, I should imagine; but no doubt there are "reports" on the different establishments. Try Hansard's, Great Queen-street, W.C., or the Queen's Printers, East Harding-street, E.C.—SAML. RAY.

[60734.]—**Wimshurst Machine.**—Seeing that the inventor of this machine has himself given full explanations in these columns, would it not be advisable for the querist to refer to Mr. Wimshurst's descriptions?—C. K.

[60735.]—**Electric Gas-lighter.**—This query has been answered over and over again. All that is wanted is a spark to pass between two points just over the gas-burner. If the portable form is meant, the latest was described in No. 1,033, p. 403; but if the battery form is required, see No. 927, p. 391.—NUN. DOR.

[60751.]—**Wiped and Blown Joints.**—Should not this query be put to the engineer of the Water Co. in question? He, I believe, insists on having screw-down taps to all domestic fittings; but screw downs, in my experience, are more wasteful than plug taps. No doubt the engineer or the authorities have a reason, as they have for preferring wiped joints. Perhaps the latter is to avoid the risk of bunglers letting the metal run into the pipes. Perhaps Mr. Davies knows.—SAML. RAY.
